Other exhibitors of smaller collections are Mr. E. Burbury, gardener to the Duke of Norfolk, Arundel Castle, with thirty dishes; Mr. J. Rust, gardener to the Marquis of Abergavenny, Eridge Castle, Tunbridge Wells, with thirty-six dishes; Mr. J. Anderson, Crawley, with twenty-four dishes; and Mr. J. Bolland, East Grinstead, with forty-seven dishes.

Mr. J. Smith, gardener to the Earl of Rosebery, Mentmore, Leighton Buzzard, contributes fifty dishes of good average fruits, Marie Louise, Duchesse d'Angoulême, Beurré Diel, Maréchal de Cour, Beurré de Capiaumont, Beurré Clairgeau, and Bellissime d'Hiver being some of the best. Mr. G. T. Miles, gardener to Lord Carrington, Wycombe Abbey, has forty dishes, comprising excellent examples of Uvedale's St. Germain, Pitmaston Duchesse, Beurré Clairgeau, Bonne d'Ezée, Catillac, Duchesse d'Angoulême, Doyenné du Comice, and Van Mons Léon Leclerc.

WILTSHIRE.—Several good growers have entered collections from this county, and the fruits generally are fairly representative, though not large. Mr. A. Miller, gardener to W. H. Long, Esq., M.P., Rood Ashton, Trowbridge, has sixty varieties. Mr. C. Warden, Clarendon Park, Salisbury, contributes twenty-five varieties, of which some fine specimens of Beurré Clairgeau from fan-trained wall trees on the Quince stock are notable. Mr. H. W. Ward, Longford Castle Gardens, Salisbury, stages forty varieties, Beurré Clairgeau and Pitmaston Duchesse being very handsome. Mr. B. Cochrane, Manor House, has eight dishes of small samples.

DORSETSHIRE.—An excellent general collection of 110 varieties is entered to represent this county from Mr. W. G. Pragnell, gardener to J. D. W. Digby, Esq., Sherborne Castle, Dorset, and the fruits from various kinds of trees on either the Quince or the Pear are handsome examples of good culture. The leading varieties are Uvedale's St. Germain, Pitmaston Duchesse, Beurré Clairgeau, Doyenné du Comice, Bellissime d'Hiver, Gratioli de Jersey, Gansel's Bergamot, Doyenné Boussoch, Vicar of Winkfield, Beurré Diel, Beurré Bachelier, Du Congrès Pomologique, a very handsome medium size and rich yellow Pear, and Colmar d'Arenberg.

ESSEX.—An important collection is that from Messrs. Saltmarsh & Son, Chelmsford, which includes eighty varieties, all meritorious, and chiefly from pyramids on the Pear stock. The best are Calabasse Grosse, Marie Louise d'Uccle, Huyshe's Bergamot, Pitmaston Duchesse, Beurré Diel, Uvedale's St. Germain, Catillac, Beurré Clairgeau, Doyenné du Comice, and a curious little oval Pear named Longue Verte Panachée, striped with light and dark green. Mr. H. Spivey, gardener to J. H. Houlton, Esq., Hallingbury Place, Bishop's Stortford, has fifty dishes, the fruits of good medium size, and from trees on the Quince stock either as pyramids, wall, or espalier trained. The finest examples are Pitmaston Duchesse, Gansel's Bergamot, Doyenné du Comice, Durondeau, Beurré Langelier, Beurré Hardy, Catillac, Passe Colmar, Nouvelle Fulvie, General Todtleben, Easter Beurré, and Glou Morceau. Mr. W. Dance, gardener to Col. A. S. H. Lowe, Gosfield Hall, Halstead, also has sixty-two varieties of good average quality.

WORCESTERSHIRE.—From Messrs. R. Smith & Co.'s well known Worcester nurseries come sixty dishes of good fruits, many of the varieties being uncommonly fine, amongst which may be named Pitmaston Duchesse, Beurré Clairgeau, Easter Beurré, King Edward, Beurré Bachelier, Uvedale's St. Germain, Duchesse d'Angoulême, Beurré Hardy, Gansel's Bergamot, Maréchal de Cour, and Passe Crasanne. Mr. W. Crump, Madresfield Court Gardens, shows samples of thirty good varieties. Mr. W. Davis, Tenbury, has forty dishes of rather smaller fruits. Mr. Gibbon, Pershore, shows a dozen sorts, and about the same number comes from Mr. W. Jenkins.

HEREFORD.—Sixty-seven dishes of handsome fruits were contributed by Mr. W. Denning from the Earl of Chesterfield's garden at Holme Lacy, where cordon trees are so admirably grown. Those shown are mostly from these, but some are from fan-trained trees, the following varieties being the most remarkable for size and good appearance:—Beurré Bachelier, White Doyenné, Easter Beurré, Duchesse d'Angoulême, Brown Buerre, Louise Bonne of Jersey, Princess, Durondeau, Beurré Hardy, Van Mons Léon Leclerc, Beurré Superfin, Beurré d'Amanlis, Hacon's Incomparable Maréchal de Cour, Beurré Rose, Forelle, Chaumontel, Doyenné du Comice, General Todtleben, Triomphe de Jodoigne, Flemish Beauty, Pitmaston Duchesse, Beurré Clairgeau, Bergamotte d'Esperen, Doyenné Boussoch, Bellissime d'Hiver. Mr. W. Coleman, Eastnor Castle Gardens, Ledbury, has seventy dishes of Pears, some of fine quality. Mr. J. Watkins, Pomona Farm, Withington, has thirty-eight dishes. Mr. Ward, gardener to Lady Emily Foley, Stoke Edith Park, Hereford, shows thirty-six dishes, the early varieties being very good; and Mr. J. Henderson, Hatfield Gardens, Ledbury, sends twenty-five varieties, none except Doyenné Boussoch being remarkable. Dr. Bull and G. H. Piper, F.G.S., have a collection of Perry Pears, under the local names, such as Pine Pear, New Meadow, Red Pear, Moorcroft, Hellen's Green, Bach's White, Cheat Boy, Rock Pear, and Knock Down, with several others bearing similar titles, but small and far from tempting.

The foregoing, with the Channel Island collections to be noted, include all the best fruits, and it is not necessary to particularise the varieties in the following, as there were few above average class, and many were below it. The number after each exhibitor's name indicates the number of dishes staged:—Messrs. F. & A. Dickson, Chester, 50, mostly good fruits from pyramid trees in open quarters; Messrs. J. Dickson & Son, Chester, have 32, fairly good; Messrs. J. & R. Pearson & Sons, Chilwell, Notts, 65; Messrs. J. Jefferies & Sons, Cirencester, 20; Mr. W. H. Bannister, Cote House, Westbury-on-Trym, 24; Mr. T. Laxton, Bedford, 64; Mr. W. Ingram, gardener to the Duke of Rutland, Belvoir Castle, Grantham, 50; Mr. Shingles, gardener to the Earl of Duncie, Tortworth Court, Gloucester, 54; Mr. Garland, gardener to Sir T. Dyke Ackland, Bart., Killerton Park, Exeter, 37; Messrs. R. Veitch & Son, Exeter, 111.

Mr. Gilman, gardener to the Earl of Shrewsbury and Talbot, Ingestre Hall, Stafford, 25; Mr. R. Mackellar, gardener to James Watts, Esq., Cheadle, 30; Mr. C. Clements, Hasley Manor, near Warwick, 12; Mr. W.

Davies, Grove Park Gardens, Warwick, 20; Mr. W. Froggatt, Chesterfield, 12; Mr. W. Gaiger, gardener to S. T. Whitehead, Esq., Derby, 13; Mr. W. H. Pownall, Lenton Hall, Notts, 24; Mr. J. N. Gleeson, Clumber Gardens, Worksop, 40; Miss Johnson, The Beeches, Carlisle, and Mr. McInnes, Carlisle, 1 dish each; Mr. J. Lends, Newport, Salop, 25; Mr. W. H. Divers, Ketton Hall Gardens, Stamford, 20; Mr. Grey, Normanton Gardens, Stamford, 30.

Mr. E. Cole, Althorpe Park Gardens, Northampton, 64 very good samples; Colonel R. T. Clarke, Welton Place, Daventry, 6; Mr. Coomber, gardener to J. A. Rolls, Esq., Hendre, Monmouth, 30; Mr. H. Ritchie, Eardiston Gardens, Worcester, 50; Miss Cheere, Popworth Hall, St. Ives, Hunts, 12; J. Plowright, Esq., Swaffham, Norfolk, 12; Colvill Brown, Esq., The Paddocks, Swaffham, 50; R. H. Mason, Esq., Necton Hall, Norfolk, 19; Mr. G. Palmer, gardener to F. H. Palmer Esq., Drinkstone, Bury St. Edmunds, 25; Mr. J. Sheppard, gardener to J. Berners, Esq., Wolverston Park, Ipswich, 19; Mr. J. McKelvie, Leadenham, Grantham, 30; Mr. F. C. Barker, Heatherdale, Woodford Green, 80; Simeon Jacobs, Covent Garden, 24 dishes of very handsome Pears from Havre; Messrs. Harrison and Sons, Leicester, 54; Mr. R. H. Poynton, Taunton, 31; Mr. H. J. Clayton, Grimston Hall, Tadcaster, 30; Mr. E. C. Hall, Bolton Hall Gardens, Bedale, Yorkshire, 45; Mr. J. Hathaway, Latham House, Ormskirk, 35; and Mr. T. Winkworth, Childwall Hall, Liverpool, 36.

WALES.—There is not a large display from the Welsh counties, and few of the fruits are above medium size. Mr. Middleton, gardener to Sir Watkin Wynn, Bart., Wynnstay, Ruabon, has sixty dishes of average fruits, *Beurré d'Amanlis* being the most notable for quality. Mr. G. Griffin, Slebeck Hall Gardens, Haverfordwest, has twenty dishes. Mr. J. Muir, gardener to C. R. M. Talbot, Esq., M.P., Margam Park, Taibach, shows twenty-four varieties, the best being *Beurré Clairgeau*, Bishop's Thumb, Black Pear of Worcester, and *Belissime d'Hiver*. Mr. Powell of Taibach also has several varieties, but not of remarkable merit.

SCOTLAND.—Some good fruits are included in some of the collections from Scotland, but they are mostly from wall trees, or in a few cases from orchard house trees, but in the majority of cases the varieties are not up to the condition they are obtained in the south. Still, several good representative collections are shown, prominent amongst them being forty varieties from Mr. Melville, gardener to the Hon. G. G. Dalrymple, Elliston House, St. Boswells, all of which resembled orchard-house fruit. The following varieties were very good:—*Nouvelle Fulvie*, *Bergamotte d'Esperen*, *Glou Morceau*, *Passe Colmar*, *Uvedale's St. Germain's*, *Winter Nelis*, *Beurré Clairgeau*, *Pitmaston Duchess*, *Durondeau*, *Marie Louise*, and *General Toddleben*. Mr. M. Dunn, gardener to the Duke of Buccleuch, Dalkeith, has sixty-two varieties. Mr. J. W. Machattie, Newbattle Abbey Gardens, Dalkeith, has fifteen. Dr. Robertson, Errol, shows fifty varieties, a very interesting collection. *Ormiston & Renwick*, Melrose, have fifty varieties, some of the best fruits from trees on a south wall and others from an orchard house. Mr. Lacaille, Errol, shows sixteen varieties; and Mr. J. Day, Galloway House, Garlieston, has thirty-five, *Pitmaston Duchess* being beautifully represented by fruits from a tree trained to a south wall.

Ireland is not strongly represented, the collection of twenty varieties from G. F. Unthank, Limerick, being the only one exhibited. These are fairly good, but not extraordinary, *Pitmaston Duchess*, *Beurré Bosc*, *Marie Benoist*, *Durondeau* and *Marie Louise*, however, being notable fruits. Mr. F. W. Burbidge, Trinity College Botanic Gardens, Dublin, sent samples of *Bishop's Thumb*, of which he stated that two thirds of the crop every year come as seedless, long, cylindrical fruits, the others being more distinctly pear-shaped.

CHANNEL ISLANDS.—Jersey has long been famed for its Pears, and it is not, therefore, surprising that the collection of eighty varieties from Messrs. J. Le Cornu & Son, St. Heliers, should contain the largest and most handsome Pears in the whole Exhibition. Single fruits of *Uvedale's St. Germain's* (shown as *Belle de Jersey* and *Belle Angévine*) weigh 1 lb. 10 ozs. *Catillac* is the same, and *Beurré Clairgeau* 1½ lb., these being 6 to 8 inches long and 12 to 15 inches in circumference. Grand fruits of the following varieties are also shown:—*Easter Beurré*, *Duchesse d'Angoulême*, *Doyenné du Comice*, *Chaumontel*, *General Toddleben*, *Van Mons Léon Leclerc*, *Louise Bonne of Jersey*, *Durondeau* (shown as *De Tongres*), *Beurré Superfin*, *Catillac*, *Maréchal de Cour*, *Beurré Diel*, *Beurré Clairgeau*, *Nouveau Poiteau*, *Doyenné Boussoch*, *Glou Morceau*, *Columbia*, *Beurré Bachelier*, *Triomphe de Jodoigne*, *Napoleon*, *Marie Louise*, and *Bergamotte d'Esperen*. From Guernsey, Mr. J. Thurston, Mount Row, contributed twenty dishes of fine specimens, of which the best were *Catillac*, *Doyenné du Comice*, *Madame Treyve*, *General Toddleben*, *Glou Morceau*, *Beurré de Jonghe*, *Souvenir du Congrès*, *Maréchal de Cour*, and *Pitmaston Duchess*.

FRANCE.—The celebrated pomologist M. André Leroy, Angers, has a very interesting collection, numbering 196 varieties, many of which are little known in England. The fruits are not large, except one giant sample of *Uvedale's St. Germain's*, weighing over 2 lbs. M. F. Jamin, Bourg-la-Reine, Paris, shows fifty dishes of handsome fruits, the following being wonderfully fine, and more like Jersey Pears. *General Toddleben*, *Beurré Bachelier*, *Fondante de Noël*, *Beurré Sterckmans*, *Beurré Bretonneau*, *Beurré Six*, *Beurré Clairgeau*, *Beurré Luizet*, *Nouveau Poiteau*, *Beurré d'Hardenpont*, *Lieutenant Poidevin*, and *Triomphe de Jodoigne*.

It may be noted that the Exhibition continues open until next Wednesday, November 4th, so that intending visitors who have not hitherto had an opportunity of seeing it may do so this week.

GREENHOUSES AND THE BUILDING ACTS.

Is a greenhouse a building within the meaning of the Metropolitan Building Acts? This is a question that is repeatedly being asked in the horticultural world, and it will continue a vexed question until an Act is passed exempting greenhouses from the operations of the respective Building Acts. As the law at present stands there is no doubt that a greenhouse is a building within the meaning of the Acts, and a person erecting one is liable to be called upon by a district surveyor to pay his fee, or, more strictly speaking, he renders himself liable to a penalty of £20 for not giving the district surveyor notice.

My impression is that it never was intended district surveyors should

have the privilege of compelling anyone who erects a small greenhouse to pay a fee for surveying it. The Acts are intended for the protection of the public, such as preventing "jerry builders" erecting dangerous structures, &c. There have been a number of decisions in the Police Courts upon this question as affecting greenhouses, but not a single case is reported where the question has been taken to the Superior Courts. The mode of appeal from the Police Court is by special case to the High Court of Justice, the cost of which would be about £20, and this is probably the reason why builders of small greenhouses prefer to pay the 15s. surveyor's fee to having the trouble and expense of an appeal.

In 1880 a case against a Mr. Norris came before the magistrate at the Clerkenwell Police Court. The defendant was summoned for erecting a greenhouse at the rear of his premises without giving the district surveyor notice, and here the magistrate decided that the greenhouse was not a building within the meaning of the Acts.

Again, in 1884, before Mr. Hosack, at the Worship Street Police Court, the district surveyor for East Hackney (North), summoned a gentleman for a fee in respect of a detached greenhouse, 16 feet long and 9 feet wide, which had been erected in a back garden, and in this case the magistrate said he would allow that a greenhouse attached to a building was not exempt, but thought one that was detached, as in this case, was exempt, and therefore dismissed the summons. In addition to these there have been many decisions both in favour of and against the district surveyor, the majority being in favour of the latter.

Magistrates and judges, as we all know, are on the bench only to administer the law as it stands, and it is of little use going to the Superior Court on an appeal in the present unsatisfactory state of the Acts, and I would suggest that the only way to alter it will be, when a new Building Act is introduced, for the lovers of horticulture to combine together to get a clause inserted, either exempting greenhouses altogether, or making the Acts so that they apply only to large conservatories or greenhouses,

Fig. 60.

say over 12 or 15 feet in height, and by this means the amateur and the small nurseryman will be relieved of the persecutions of the district surveyor.

The Metropolitan Building Act, 18 and 19 Vic., cap. 122, is the principal Act under which district surveyors claim to interfere with the enthusiastic amateur or nurseryman who erects a greenhouse. Sec. 6 of that Act refers to greenhouses as follows:—"The following buildings and works shall be exempt from the operation of the first part of this Act. All party fence walls and greenhouses, so far as regards the necessary woodwork of the sashes, doors, and frames." Sec. 31 says, "With the exemptions hereinbefore mentioned, every building, and every work done to, in, or upon any building, shall be subject to the supervision of the district surveyor appointed to the district in which the building is situate." And sec. 38 deals with the notice to be given to the district surveyor two days before commencing building.

Many persons are under the impression that by placing a greenhouse on wheels they do not come within the Acts. Prior to 1882 it may have been possible to avoid the operation of the Acts in this way, and probably it was in consequence of this being done that the 13th section of the 1882 Act was inserted, which is as follows:—"The Metropolitan Management and Building (Amendment) Act, 45 and 46 Vic., cap. 14, sec. 13. "It shall not be lawful for any person to set up in any place any wooden structure or erection of a moveable or temporary character, unless the same be exempt from the operation of the first part of the Metropolitan Building Act, 1855."

It is possible, under exceptional circumstances, to erect a greenhouse which is exempt from the operation of the Acts, as I know from experience, having had considerable difficulty with a district surveyor in the erection of my third greenhouse (the first two were erected without his aid). He wanted to insist upon my bricking up the front of the house to the sills with 9-inch brickwork and the necessary footings under schedule I. of the Act of 1855, which is as follows:—"Every building shall be enclosed with walls constructed with brick, stone, or other hard and incombustible substance; and the foundations shall rest on the solid ground, or upon concrete or upon other solid substructure." To this I protested, and positively declined either to put a single brick in the building or pay a surveyor's fee.

The greenhouse (fig. 60) was built principally for the purpose of blooming Chrysanthemums in, and as all Chrysanthemum growers know, in order to keep the plants healthy, a plentiful supply of ventilation is necessary both above and below the stage. I had the good fortune to have walls at the end and on either side of my garden, which is 17 feet 3 inches wide, and I determined to avail myself of these walls by erecting a square span-roof house the whole width of the garden, and putting in a front as shown in the accompanying sketch. For ventilation it will be seen I have a lantern light at the top, a patent Moore's ventilator over the door, and four doors opening outwards upon hinges fitted into the framework below the sills. These are the doors the district surveyor endeavoured to compel me to remove and replace with 9-inch brickwork, and thus destroy part of my ventilation.

By erecting it in this way it will be seen I have a greenhouse which is composed entirely of sashes, doors, and frames, and as that portion of a greenhouse composed of sashes, doors, and frames is exempt from the operation of the Acts, I contended, and successfully, that this house did not come within the Building Acts. My contention was not the old question, Is a greenhouse a building within the Acts? but, Is my greenhouse a building? &c.

As before stated, I had some difficulty with the district surveyor, who refused to accept my reading of the Acts, and a lengthy correspondence passed between us. He would insist upon visiting my premises a number of times while the building was in course of erection, and when completed he sent me an account as follows:—"For surveying one building, being a certain building under 400 square feet in area and one storey in height, and being situate, &c., &c., £1." To this was affixed a receipt stamp, across which was written, "Received the above," and signed. A letter from the district surveyor accompanied the receipt, stating it was sent to show he was not "fighting for his fee."

There are two things connected with this receipt which are somewhat amusing. In the first place I had never been requested to pay the £1, and in the second place the Act of 1855 sets out a schedule of charges the district surveyor is entitled to make as follows:—

FEES PAYABLE TO DISTRICT SURVEYOR.

Fees for New Buildings.

For every building not exceeding 400 square feet in area, and of one storey only in height, the fee shall be... .. £0 15 0

It may be well to mention that before the tenant erects a greenhouse similar to the one represented in the sketch he should take every precaution, as it is both expensive and annoying after erecting a greenhouse to find someone in a position to interfere and insist upon structural alterations being made or the removal of the house. For instance, the tenant should have either a clause inserted in the agreement or lease under which he holds his premises, or obtain an undertaking from the landlord, to the effect that he may be at liberty to erect greenhouses and remove them at the expiration of the tenancy, otherwise the tenant may find he has erected a house which his landlord will in all probability endeavour to insist upon his leaving upon the premises. In addition to this the house should be built with gutters to catch the rain, so that the wet does not run off the roof upon the walls. If eaves or gutters are erected over a neighbour's land he has the legal right to have them pulled down without waiting for an actual inconvenience to arise, therefore it is advisable that the neighbour's permission should be first obtained.

From the above facts it will be seen that an ordinary greenhouse, whether on wheels or planks, is without doubt a building within the meaning of the Building Acts, and that directly an occupier commences to erect even one of the smallest greenhouses we find advertised as tenant's fixtures, the district surveyor appears upon the scene and claims to have the right, under the Act of 1855, to compel the unfortunate horticulturist to put brickwork up to the sills, and then at one stroke, not only makes the greenhouse a landlord's fixture, but brings the structure under the Building Acts, which enables him to claim his fee for surveying a greenhouse, which often is so simple that it scarcely deserves to be called a structure.

I have several times used the term "tenant's fixture" in the above article, this is a question which is far from clear and equally as interesting as the present one, and upon which a deal may be said; but as space will not permit I must leave my remarks upon tenants' fixtures for some future occasion.—GEO. S. ADDISON.

CHRYSANTHEMUM NOTES.

THE FROSTS.—There is no doubt but that the early frosts in September played sad havoc in the gardens, more especially in the low-lying districts. I can truly sympathise with your correspondent "A. A." (page 362). It must have been saddening to see all the flower buds cut up as described by him, and to find one's labour for the whole year thrown away and the loss of a floral display. This is one of the many things that a gardener has to bear; fickle seasons, diseases, birds, and insects wage warfare with him on every hand, and with truth, "Love's Labour Lost" might be written across many a label after the loss of a crop through no fault of his own. Happily we have many bright sides to the picture that bears us up through all the disappointments of the seasons. Although living but about four miles as the crow flies from "A. A., Mitcham," the frosts did not hurt my plants of Chrysanthemums that I had out of doors on account of our place being at a much higher elevation. I expected we should have had a little frost, and consequently took the precaution to house temporarily in a shed all that was then showing colour. Often the

effect of frost on the buds is not seen until the blooms begin expanding, when the tips of the florets soon begin to decay, as if scalded.

VARIETIES.—One of the earliest to flower with me this season is *Flamme de Punch*. This variety is now at its best. I first grew it last year, so these flowered rather early; a good type of a Japanese Chrysanthemum, with long drooping florets and a full centre, but the colour was not at all pleasing, it was of a dull rusty brown. This season it has come much better in colour, with a yellow stripe down the centre of each floret. It is very distinct, and I should think a good amateur's flower.

MARGOT.—This is, like the preceding, a variety of recent introduction—and a great acquisition both as a decorative and an exhibition flower. It is quite a new and fashionable colour, and sure to be a favourite with the ladies. It may be described as a beautiful soft rose, with a cinnamon buff tint diffused through the whole flower.

MONS. ASTORG.—This is another valuable addition to the white-flowering varieties, and I think it will fully bear out the opinion I formed of it last season as a grand show flower. The outer petals open out with a pink shade on the outside, but when they are more fully developed they spread out and fall over in a very graceful manner. The petals are broad and of good substance and of a pure ivory white.

MDLLE. LECROIX.—Is another early-flowering white now pretty well known. It has long drooping petals, more or less twisted, of a creamy white. An early variety of good habit. It has a good constitution and is very constant, the flowers keeping well.

PORCUPINE.—I refer to this here, as I have already seen the name mentioned in the daily papers as a new variety amongst others at the public exhibitions in London. I had a cutting sent me this spring, and I recognised it by the foliage as *Gloire Rayonnante*, commonly called the Hedgehog, on account of the quilly nature of its florets. It is now in flower with me, and is no other than the old friend I have mentioned.

GLORIA SOLIS.—This is in the way of *Bronze Dragon*, but of a deep guinea gold colour, splashed with bronze. If it will come full up in the centre it will be a great acquisition in colour.—C. ORCHARD, *Coombe Warren*.

WATERING CHRYSANTHEMUMS.—In my experience, and it is somewhat extensive, two cardinal mistakes are made by inexperienced growers in watering these plants. The first is not giving them sufficient liquid support at the right time in summer when the pots are filled with roots, the sun bright, and air dry. At that time they may be watered twice or even thrice a day, and yet not be satisfied if the soil is permitted to shrink from the pots before water is given. Good growers never allow such a mistake as that, and they keep the roots moist without saturating the soil with less water than is needed when the shrinkage alluded to is thoughtlessly allowed. The next mistake consists in giving the plants too much water after they are housed in the autumn. I have heard gardeners say Chrysanthemums cannot have too much water then, and it is given, often strong liquid manure, every day; in fact, in years gone by I had to carry out that practice, and I now know that I ruined many plants "by order."

I have just been in two gardens. In one of them Chrysanthemums are so fine that the blooms are almost certain to win high honours at some of the great shows; in the other there will be few if any flowers of it for exhibiting. In the former case not a drop of water was given to a plant until the pot was rapped and the soil tested. The soil in many pots passed by the waterer "looked dry," but he knew it contained sufficient moisture for the plant that day, and to have given it when not wanted would have done harm and not good. Though the huge plants, clothed to the ground with splendid foliage and showing great fat expanding buds, are only in 8-inch pots, it is almost certain that they are not watered more than twice or thrice a week—that is, those watered to-day will not need a further supply for two or three days, according to the condition of the varieties and the weather; indeed, one plant that accidentally got too wet would not require, nor receive, a drop more water for a week.

In the other garden no such care was exercised. The young man said he gave them "good stuff" every day. It was a "single-handed" place, and in many such gardens Chrysanthemums are remarkably well grown. In this I am bound to say they were simply being ruined. In some of the pots the soil was saturated and poisoned with liquid manure too strong by half. I am quite positive that some of the small plants in large pots would be better without a drop of water for a week, even if the weather were bright, while if dull the soil would remain wet for a fortnight. The plants had lost most of their foliage, and though the soil was quite wet, much too wet, the leaves remaining were flagging with the sun—a certain indication of the roots being injured by too much water and too strong doses of nitrate of soda. The plants had in all probability been drawn up and weakened when young, not potted soon enough, and the earnest young man was striving to make up for lost time; but he was too late and too earnest, and I am sorry to say will not be able to cut six blooms from 300 plants that can win a third prize at a good show.

To grow Chrysanthemums in first-class style stout cuttings must be had, the plants kept sturdy, never checked in any way, and must be watered with as much care as if they were Heaths. These may be easily ruined by under-watering in summer and over-watering in the autumn, and so may Chrysanthemums.—AN OLD EXHIBITOR.

YIELD OF POTATOES.

HAVING seen several notes in the Journal of the yield of Potatoes, I send you an account of what has been grown here this season, the soil

being very heavy. I grow about a dozen varieties, including Ashleaf and Early Regent, which is the best second early I have got, the crop and quality being first-class. From half a pound of the latter planted for trial on 9th April I lifted 119 lbs. on August 17th, all sound. For the main crop I grow Reading Hero, Magnum Bonums, and Reading Russet, the former being the chief one, the quality being so good. From sixty perches planted in the middle of March, we lifted at the end of September over four tons of good Potatoes, three tons of Hero and one of Magnum, with about 3 cwt. of small ones over the four tons. I cannot come up to some of your correspondents in weight of tubers, but there are plenty weighing about 1 lb. each. I may say that Potatoes in this neighbourhood have not done well this season in general, the produce being small, with second growth in many cases.—W. WHITTAKER, *Manor House, Stockland, Bridgwater.*

ROYAL HORTICULTURAL SOCIETY.

OCTOBER 27TH AND 28TH.

THE concluding Show of the series of twelve provided at South Kensington since the beginning of May this year was devoted to Vegetables and Chrysanthemums, and was as satisfactory as those which preceded it. The entries were very numerous in all the classes, and the competition remarkably keen in consequence of the uniform good quality of the exhibits. During these six months a wonderful quantity of horticultural produce has been brought to the exhibitions, and there can be no doubt that the prizes offered have induced much healthy rivalry, which has imparted an invaluable stimulus to horticulture generally. It is to be hoped that a similar series of shows will be provided next year.

VEGETABLE AND CHRYSANTHEMUM SHOW.

COLLECTIONS.—The competition was exceedingly strong with collections of eight kinds of vegetables, no less than eighteen exhibitors entering, and their produce was as fine and clean throughout as anyone could desire. Mr. G. F. Miles, gardener to Lord Carrington, Wycombe Abbey, gained the premier award with a grand collection, one of the best he has shown for some time, and including admirably grown examples of Veitch's Autumn Giant Cauliflower, Sutton's New Intermediate Carrot, Walker's Exhibition Onions, Veitch's Exhibition Sprouts, Stamfordian Tomato, Leicester Red Celery, Chancellor Potatoes, and Lyon Leeks. Mr. R. Phillips, gardener to Dr. Baker, The Decdars, Meopham, and Mr. S. Haines, gardener to the Earl of Radnor, were second and third, their vegetables being very few points behind the first in quality.

POTATOES.—There was an extensive display of Potatoes, and the majority of the exhibits were of fine appearance. With thirty varieties Mr. J. Hughes, gardener to Colonel Cartwright, Eydon Hall, Byfield, took the lead amongst four other exhibitors, and showed handsome even tubers of Beauty of Hebron, Pride of Eydon, London Hero, Cardinal, Reading Russet, Schoolmaster, Queen of the Valley, Cosmopolitan, Woodstock Kidney, Edgemoor Purple, Vicar of Laleham, Chancellor, Snowdrop, Prizetaker, Lord Rosebery, The Dean, Fidler's Prolific, Rufus, The Captain, M.P., Crimson Beauty, The Colonel, Red Fluke, Adirondack, Sutton's Early Regent, Purple Perfection, Myatt's Prolific, Favourite, and Magnum Bonum. Mr. E. S. Wiles, Edgemoor, Banbury, and Mr. William Kerr, Dargavel, Dumfries, were second and third, each with good specimens. Ten competitors staged twelve varieties. Mr. William Ellington, West Row Gardens, Mildenhall, Suffolk, taking the first place for excellent tubers of Grampian, Chancellor, Beauty of Hebron, The Doctor, Vicar of Laleham, Adirondack, Edgemoor Purple, Magnum Bonum, Lee's Defiance, Lord Beaconsfield, Lifeguard, and Snowdrop. Messrs. E. S. Wiles and J. Hughes followed closely. Mr. W. Robins, gardener to E. D. Lee, Esq., Aylesbury, had the best six varieties of the fourteen lots staged, the varieties being Mr. Breese, Radstock Beauty, Schoolmaster, Reading Hero, International Kidney, and Vicar of Laleham. Messrs. E. S. Wiles and William Ellington were second and third respectively.

MESSRS. SUTTON'S PRIZES.—Messrs. Sutton & Sons, Reading, contributed prizes in two classes for Potatoes, the principal being that for nine varieties selected from eighteen sent out by that firm. Mr. J. Donaldson, The Gardens, Keith Hall, Inverurie, was awarded the premier honours amongst twelve competitors with capital clean tubers of Lady Truscott, Magnum Bonum, Fiftyfold, Woodstock Kidney, Favourite, Prizetaker, Reading Russet, First and Best, and Reading Hero. The other awards were secured by Messrs. Haines, gardener to the Earl of Radnor, Colleshill, Highworth, Berks; C. W. Howard, Bridge, Canterbury; and Mr. C. Ross, Welford Park Gardens, Newbury. In the other class for two varieties, Early Eclipse, a white round, and Reading Ruby, a long red handsome kidney, Mr. J. Donaldson was again first, Messrs. E. S. Wiles and S. Haines being second and third, all showing good samples, though the first were much the best.

Mr. C. Fidler, Reading, also provided a class for four dishes to comprise Fidler's Success, Prolific, and Enterprise, and Reading Russet. Mr. J. Hughes was adjudged the chief prize, and was followed by Mr. E. S. Wiles, Mr. C. Osman, Sutton, and Mr. Ellington, there being in all eight exhibitors.

ONIONS.—These were well represented by solid handsome bulbs, twenty-six dishes of nine being entered in the class devoted to them, fifteen of these being Rousham Park Hero. Mr. G. Neal, gardener to P. Southey, Esq., Bampton, Oxford, was first with Deverill's Anglo-White Spanish, large, even and handsome. Mr. E. S. Wiles followed with the same, not quite so large, and Mr. Aggins, gardener to the Earl of Effingham, Tusmore, was third with Rousham Park Hero. Mr. H. Deverill, Cornhill, Banbury, provided four prizes for the best dishes of the following varieties:—Rousham Park Hero, eleven entries, won by Mr. Henley, Banbury; Anglo White Spanish, six entries, Mr. G. Neal; Main Crop, seven entries, Mr. E. S. Wiles; Finlay's Wroxton, seven entries, Mr. Doherty, gardener to Lord North, Wroxton Abbey. Mr. Deverill also showed a collection of twenty-eight varieties that, like the preceding, were distinguished by fine quality.

Numerous classes were devoted to vegetables, in which the following were the winners of the principal prizes. There were twenty lots of six heads of Celery, Mr. G. H. Richards, gardener to the Earl of Normanton, Somerley Park, Ringwood, Hants, being first with Wright's White, solid white samples, much the best shown. Sutton's Sulham Pink, and Luck-

hurst's Giant White were the other winning varieties. Mr. Richards was also first with Parsnips amongst twenty-two exhibitors, having fine specimens of Elcombe's Improved, and again with Turnips the same exhibitor was first with Snowball. The best of eighteen exhibits of Carrots was shown by Mr. W. H. Kingsmill, Newbury, clean handsome specimens of Sutton's Intermediate, 14 to 16 inches long. Mr. May, gardener to Captain Le Blanc, Northau House, Barnet, had the finest four plants of Brussels Sprouts, capital examples of his well-known strain. For half a peck of Sprouts, Mr. R. Lye, gardener to W. H. Kingsmill, Esq., Newbury, was first with Sutton's Exhibition variety, close neat sprouts. Endive was admirably shown by Mr. G. Bolas, gardener to H. C. P. Gell, Esq., Hopton Hall, Wirksworth, who had selections of Messrs. Sutton's. The best Beet was Pragnell's Exhibition from Mr. May, fine even roots. Autumn Giant Canli-flowers of medium size gained Mr. Haines the first prize, and were preferred to much larger heads. The same exhibitor also had good specimens of Lyon Leek, and led in a class of nineteen competitors. Mr. C. Osman showed fine examples of Sutton's Allheart Cabbage, and was placed first, as he was also with Drumhead and Red Cabbages.

Fifteen dishes of highly meritorious Tomatoes were staged, all being forms of Trophy. Mr. R. Farrance, Chadwell Heath, was first with grand even richly coloured fruits; Mr. N. Phillips being a very close second with rather smaller but equally beautiful fruits; Mr. Worthing, gardener to A. Ross, Esq., Chadwell Heath, being third. Gourds made an interesting display, the fruits being most curiously formed and brightly coloured. Messrs. C. Osman, Glen, and J. Sharpe were the prizetakers.

CHRYSANTHEMUMS.—In the class for a group of Chrysanthemums in pots Mr. G. Stevens, Putney, won first honours with an exceedingly tasteful contribution, the plants well grown, and the blooms, chiefly Japanese, of good size, bright, and clean. There was a margin of dwarf plants in front, principally L'Africaine, which formed an agreeable finish to the group. Mr. A. Cuff, gardener to R. R. Hyatt, Esq., Leigham Court Road, Streatham, was second, his group being fairly well arranged, but the blooms were small; Mr. C. E. Smith, Silvermere, Cobham, being third with loosely arranged rather late plants, but bearing fine blooms of Mdle. Lecroix, Mrs. Marsham, Comte de Germiny, and Queen of England.

Six remarkably good collections of twenty-four blooms were entered for such an early period in the season. Mr. J. Ridout, gardener to T. B. Haywood, Esq., Woodhatch Lodge, Reigate, being awarded the leading prize for a dozen Japanese, exceptionally fine, and the same number of incurved, several of which were also good. The varieties were, Japanese—L'Incomparable, Mdle. Lecroix, Dr. Macary, Madame Auguste Gautier, Criterion, Margot, Chang, Madame de Serin, Madame Rendatler, Madame C. Audiguier, Soliel de Levant, and Rubrum striatum. Incurved—Queen of England, Jeanne d'Arc, Empress of India, Nil Desperandum, Mrs. G. Rundle, Mrs. Dixon, Baron Benoist, White Venus, Mr. Bunn, Prince of Wales, Mr. G. Glenney, and Lady Hardinge. The second place was taken by Mr. J. J. Lowry, gardener to James MacAndrew, Esq., Belmont, Mill Hill, who had splendid blooms of several Japanese varieties, such as M. Henri Jacotot, Md. Astorg, Mdme. Audiguier, M. Desbrieux, Margot, M. Moussilac, Dalmio, Berthe Rendatler, and Magnum Bonum. Mr. C. Goode, gardener to G. G. Stone, Esq., Eastcote, Red Hill, was third, his best blooms being Madame C. Audiguier, Roseum Superbnm, and Margot.

MISCELLANEOUS.—A silver-gilt medal was awarded to Messrs. Sutton and Sons, Reading, for a superb collection of Potatoes and Kales. There were three large heaps of Reading Hero, Magnum Bonum, and Reading Russet, all fine tubers. Eleven dishes of unnamed seedlings were also shown with samples of the produce of the Darwin Potato, Solanum Maglia. There were eighteen dishes of varieties sent out by the firm, and thirty-four of general varieties, all distinguished by their fine appearance. Of the Kales, the Exquisite Dwarf Green Curled, Dwarf Purple, and Improved Variegated were very beautiful. Silver medals were awarded to Mr. W. Kerr, Dargavel, Dumfries, for 100 dishes of Potatoes, comprising many varieties all superbly represented by clean handsome tubers. M. M. Vilmorin et Cie, Paris, showed an interesting collection of about 100 old and new varieties of Potatoes, some of which have been cultivated by them for eighty years. The Marjolin Hâtive, the Early Ash-leaved Kidney, was notable, as were also several forms of the Vitelotte or Fir Apple type, some of which are quite cylindrical and long, strangely and regularly indented, which is most marked in a small form called Asperge. To Mr. J. Deverill for the Onions already noted; and to Mr. Dance, gardener to Col. Lowe, Gosfield Hall, Halstead, for eighty dishes of Apples and Pears, comprising many large handsome fruits. Bronzes medals were awarded to Mr. C. Fidler, Reading, for an extensive collection of Potatoes; and to Messrs. Hooper & Co., Covent Garden, for a choice group of Carnations and Gesneraceous plants, including numerous handsome varieties.

COMMITTEES.

FRUIT COMMITTEE.—Harry J. Veitch, Esq., in the chair. Present:—Messrs. Paul, Ford, Ross, Haywood, Roberts, Bunyard, Blackmore, Hogg, and Burnett, and Mr. A. F. Barron, Secretary. Mr. Pritchard, Queen Street, Sittingbourne, sent an Apple named St. Christopher; the fruit tasted of the packing, and it was requested to be sent again, when six fruits must be shown. Mr. A. Lancaster, Holkham Hall, Norfolk, sent a large handsome Apple named Lord Leicester. It has a very firm, crisp, and agreeably acid flesh, and promises to be a long-keeping kitchen Apple of great merit. It was placed in charge of Mr. Barron, with the request to be brought forward later in the autumn at a subsequent meeting. Mr. William Earl-y, Ilford, sent a dish of a large variety of Apple from a seedling grafted eighteen years ago. It bears a strong resemblance to Lord Derby, and the Committee asked to see it in June or as late as it was in condition. Mr. Cummins, gardener to A. H. Smee, Esq., Wallington, sent an Apple named Smee's Seedling, which was past. He also sent tubers of Magnum Bonum Potato, some of which weighed 2 lbs.; a vote of thanks was awarded. Messrs. John Peed & Sons sent a seedling Plum found in a hedgerow, a prolific variety keeping till Christmas. It was very acid, and the Committee requested that it be exhibited again next year. G. F. Wilson, Esq., Heatherside, Weybridge, sent a Pear named Bœurré d'Anjou from a tree grown in a pot for the last twenty-eight years; a vote of thanks was awarded. Mr. Jones, Carshalton, sent Celery Plein blanc dorée, to which a vote of thanks was awarded. Mr. Miles, Banbury, sent a variety of Brussels Sprouts called Edgemoor, which was passed.

FLORAL COMMITTEE.—G. F. Wilson, Esq., in the chair. Present—Messrs. J. Douglas, John Laing, W. Bealby, J. Child, H. Herbst, J. James, John Fraser, Thos. Baines, John Dominy, H. M. Pollett, E. Hill, H. Cannell, H. Ballantine, H. Turner, James O'Brien, Henry Williams, Amos Perry, Shirley Hibberd, and M. T. Masters.

Messrs. J. Veitch & Sons, Chelsea, exhibited several new Chrysanthemums, all Japanese, the best being Lakme, bright red; Melanie Fabre, of a rosy tint; Souvenir d'Haarlem, like Margot, but of a deeper colour; and Lady Rosebery, one of Salter's varieties, with flat florets of a pale rose or blush colour. A botanical commendation was awarded for *Peristeria pendula*, bearing wax-like flowers dotted with purple. *Amazonia punicea* with scarlet bracts and yellow tubular flowers, was also shown, together with a fine plant of the graceful *Davallia retusa*, and a collection of *Bouvardias*, comprising President Garfield, double pink; Alfred Neuner, double white; Maiden's Blush, pale pink; Leiantha, very bright scarlet; Priory Beauty, soft blush pink, handsome; Vreelandi and Umbellata Alba, white, and Elegans, scarlet. A vote of thanks was accorded for a plant of *Eugenia Ugni* bearing numerous fruits. Votes of thanks were also accorded for the following: To Mr. Cummins, gardener to A. H. Smee, Esq., The Grange, Wallington; to James Bateman, Esq., Worthing, for sprays of *Acacia retinodes*, with small yellow flowers; to Mr. B. S. Williams for *Echmea imperialis* of the Marie Regine type, with large drooping crimson bracts, and *Sarracenia Flambeau*, a hybrid between *S. psittacina* and *S. variolaris*; to Mr. Robert Owen, Maidenhead, for cut blooms of Tuberous Begonias and Chrysanthemums; to Messrs. H. Cannell & Sons, Swanley, for blooms of Zonal Pelargoniums Swanley Gem and Henry Cannell, both grand varieties, rosy salmon and deep crimson colour; to Mr. S. Forbes, Roehampton, for a stand of Chrysanthemum blooms; to Messrs. E. G. Henderson, Pine Apple Place, for Nerine elegans cœrulea, a variety with a purplish tinge in the flowers; and to Mr. Ridout for blooms of Tea Roses very fresh and beautiful, especially President, Annie Ollivier, Souvenir d'un Ami, Mons. Lambard, Etoile de Lyons and Catherine Mermet. C. Norman Cookson, Esq., Wylam-on-Tyne, showed several beautiful hybrid Calanthes, two of which were certificated, others being named C. Normani, white with a red eye, and C. Sedeni candidula, red with a white eye.

CERTIFICATED PLANTS.

Cattleya autumnalis (J. Veitch & Sons).—A small-flowered but extremely pretty variety, with purplish sepals and petals, a crimson lip with a white throat.

Chrysanthemum Val d'Andorre (Mr. Wright, Middle Temple Gardens).—A Japanese variety shown last year, having flat or slightly fluted florets streaked with bright red on a yellow ground. Blooms large and of good substance.

Sarracenia Buchani (B. S. Williams).—A hybrid between *S. rubra* and *S. purpurea*, dwarf, the pitchers 6 to 8 inches high, the lid broad, rounded, and erect, and the colour an extremely rich dark red with darker veins.

Cymbidium elegans (B. S. Williams).—A strong-growing plant, with leaves like *C. Lowianum*, the flowers $1\frac{1}{2}$ inch long, tubular in form, of a peculiar buff tint, and borne in dense pendulous racemes.

Nepenthes Excelsior (B. S. Williams).—A hybrid between *N. Hookeriana* and *N. Rafflesiana*, with pitchers of medium size, of neat form, and finely mottled with bright red.

Calanthe Alexandri (Norman C. Cookson, Esq., Oakwood, Wylam-on-Tyne).—A beautiful hybrid between *C. Veitchi* and *C. vestita rubra oculata*, the flowers of an intensely deep crimson colour, the two lower sepals whitish.

Calanthe Cooksoni (Norman C. Cookson, Esq.).—A hybrid between *C. Veitchi* and *C. vestita luteo-oculata*, one of the grandest white forms yet obtained, the flowers very large, of handsome shape, and pure white, with a light yellow eye.

AUTUMN SHOWS.

EXHIBITORS of Chrysanthemums will soon be actively engaged in preparing for the numerous shows announced for the present season, and the following list of fixtures may be useful as a reminder. Secretaries of Societies not mentioned will oblige by forwarding their schedules.

- October 21st to November 4th.—Chiswick (Pear Congress).
- November 3rd and 4th.—Ealing, Southampton, and Lambeth.
- " 4th and 5th.—Brixton.
- " 5th and 6th.—Richmond, Havant, and Highgate.
- " 9th and 10th.—Stoke Newington.
- " 10th.—Southend and Putney.
- " 10th and 11th.—Brighton and Kingston.
- " 11th.—Basingstoke.
- " 11th and 12th.—National Chrysanthemum Society and Croydon.
- " 12th and 13th.—Lindfield and Portsmouth.
- " 13th and 14th.—Huddersfield.
- " 14th.—Ramsbottom.
- " 17th.—East Grinstead and Devizes.
- " 17th and 18th.—Lincoln, Manchester, and Winchester.
- " 18th and 19th.—Northampton, Bristol, Burton-on-Trent, and Birmingham.
- " 19th.—Taunton, Hammersmith, and Aylesbury.
- " 19th and 20th.—Hull.
- " 20th and 21st.—Sheffield.
- " 24th.—Liverpool.

LATE GRAPES AND CHRYSANTHEMUMS.

As proposed in the columns of the Journal by "A Surrey Gardener," seconded by Mr. Stephen Castle, and finally accepted by Mr. H. Holmes (Hon. Sec.) on behalf of the Committee of the National Chrysanthemum Society, that a Grape class or classes should be added to the January, 1886, Exhibition of Chrysanthemums to be held at the Royal Aquarium, Westminster. I think the idea is a good one, and I am of opinion that to make it a representative Show of late-keeping varieties several classes should be added for both black and white varieties, such as Lady Downe's Seedling, Alicante, and Gros Colman; for white variety, Muscat of Alexandria, and Golden Queen as any other variety of white Grape. Those who attended the Grape Show in September at South Kensington would notice how badly Golden Queen was represented. There were

only two exhibits, and they were quite green, simply because it is a late Grape. I think nothing is so damaging to the character of this Grape as showing it in an unripe state. I do not maintain that it is a first-class Grape not to be compared with Muscat of Alexandria and some other white Grapes. I have heard several persons speak of it as good for nothing, and not worth growing; but with me it has proved to be a very useful late Grape after Christmas when other white varieties have been over, and it grows and ripens equally well with Alicante and Lady Downe's Seedling. I have seen this Grape at some of the late autumn shows in very fine condition, but unless a class is provided for it I do not think it would be shown in competition with Muscat of Alexandria. Can any reader of the Journal inform me if Gros Maroc is a late-keeping variety?—A. O. W.

JUDGING GRAPES.

I DID not state that the "popularity" of the Alicante was the only ground claimed by "A Kitchen Gardener" for its superiority; but it certainly is the principal ground which he has to stand upon. He asks me if I can see nothing more in his notes than the brief distinction of popularity. Yes, I see attempts made to establish the superiority of Alicante over Madresfield Court; but, as far as I can see, only attempts. We are fully aware that there are not nearly as many Vines of the latter variety planted as of the former, and I think that the principal reason for this is that Alicante is easier to grow, not because it is a superior Grape. Madresfield Court might be much more planted if it were not written about as on page 292 by "A Kitchen Gardener." In our own case, for the first two seasons it failed to colour properly and also cracked somewhat badly, but this was no doubt partly owing to wrong treatment. This season we were able to cut bunches good enough to accompany the Alicante amongst the eight which were placed second at the Royal Caledonian Society's Show. So I say to those who have not yet succeeded, Try again, for it is worth a little trouble.

"A Kitchen Gardener" would almost make your readers believe that because the grand bunch of Madresfield Court shown at Edinburgh was not mentioned in the report, that it was not equal to Alicante which is shown so well in all the collections, or, indeed, that it was nothing out of the common; but the fact is, that it was shown in the class "for any black not named in the schedule," and as far as I remember very little mention was made of any of the double and single-bunch classes, I presume simply because it would occupy too much of the valuable space of the Journal. It certainly was not because they were not deserving of notice. I am pleased to see that Mr. D. Buchanan has lately given an accurate description of the bunch to which I referred on page 342, which saves me the trouble of saying any more about it, except that I think with the many that it was the finest bunch in the Show, all things considered. It may not, as "A Kitchen Gardener" says, "speak highly of its abundance;" but is abundance to be considered the test of merit? Judging from what we too often see at shows, appearance is very often regarded as the test of merit; but, as Mr. Iggulden says on page 342, I certainly think that the present discussion will cause Judges to reflect a little more before making their awards next season; at any rate, let us hope so. We do not wish to exclude Alicante and other fine late Grapes from our autumn shows. That is not the point under discussion; the principal question put by Mr. Iggulden at the commencement was, Is appearance to go before quality? or questions to that effect. If "A Kitchen Gardener" cannot grow Madresfield Court himself, he ought not to discourage others who are willing to try.—WM. JENKINS.

KITCHEN GARDEN.

FORCING.—Kitchen garden work is not pressing just now. The whole of the crops which are of any use this season are in and left to go on as best they can, and the most important matter to be considered is the forcing of those roots, the produce from which is so much valued about Christmas and during the winter. Preparation for this should begin at once. There are two ways of doing the work; one is by the aid of fermenting material, the other by the help of hot water. Where a well-heated pit or Cucumber-like house is at command successful forcing is a very easy matter. It is not very difficult either with fermenting material, but not so quick as with the hot water. Fallen leaves, which are now very plentiful, and manure from a stable, are the best materials for hotbed-making.

RHUBARB.—This is very easily forced by the aid of these. Some large pots, old boxes, or empty casks should be turned upside down over the crown of each clump of Rhubarb, and then a good heap of the fermenting material should be put around each of these. It should be made as firm as if it was being formed into a hotbed of the ordinary kind, and the material should not be put on merely to cover the box, or whatever it may be, but it may extend over the whole of the space where the roots are, as it is by the heat penetrating the soil and exciting these that growth is produced quickly. The stems would never spring up if surface heat alone

was applied, and when the soil is warm it does not matter much whether the interior of the cask, or whatever it may be, is heated or not. The upper end of the cask should only be a little way from the surface, so that it can be conveniently examined occasionally to see how growth is going on, and cutting ought to be done without having to upset anything to get to the stems. This is our favourite way of forcing Rhubarb. We are just covering a few roots now; more will be covered in three weeks or so, and others again when necessary, and our supply will begin about the middle of December, and lasting, if we wish it, until growth is natural in the open air. We have lifted the roots and forced them in a house, but the produce was not so fine as from under the manure, and we also preferred the flavour of the old cask produce. No roots will bear forcing for two years in succession, and no attempt must be made to force those which underwent the operation last winter. When our roots become too large we split them into a number of pieces, make plants of each, and we have never any scarcity of forcing roots. Those which are forced in the ground will grow strong again if protected until the spring, but those taken up for forcing are of very little use afterwards.

ASPARAGUS.—We have put in our first batch of roots of this, and will send the first to table by the first week in November or thereabouts. Nothing gives so much satisfaction as a forced vegetable as Asparagus. We plant out about 300 young roots annually, force the same number, and we have always a full supply. Last winter, and for many before that, we lifted some of the strongest of the roots for forcing from our quarter-acre bed. In spring these blanks were well manured and filled, and this system of lifting and replanting goes on annually.

The roots are put in about 3 feet apart each way, and we find this way of working acts uncommonly well. In beginning to force the stems are cut over close to the surface, the roots are dug up without breakage, and then they are packed in as closely as they can be put in a layer in the bed of a Cucumber pit. A little soil is put under them, more over them to cover the crowns; then a watering is given, and with a bottom heat of 80° and a top heat of 65° many fine heads soon appear. No attempt is made to blanch it, as it is more tender and much better flavoured green. Sometimes part of the Cucumber pit bed is empty to receive it, and if not the roots are put in round the mounds in which the Cucumber plants are growing. We put in two or three dozen large fully matured roots once a fortnight or so, and keep on cutting so long as we care to put the roots in. At times when space under glass was scarce we have made a large hotbed, placed a frame on the top of this, and put the roots inside on the top of the manure, covering them with a little soil, and keeping the lights close afterwards. It does not grow so quickly here as with the Cucumbers, but otherwise the forcing was very successful.

SEAKALE.—The leaves have not died from the Seakale crowns yet, but they will soon go, and then forcing may be commenced. Pots or boxes may be used for going over the crowns, and the hotbed system which is recommended for Rhubarb will produce excellent Kale. Growth is not very rapid at this season, and forcing should commence five weeks or so before the produce is required. Only strong well-ripened roots need be taken in hand now, as none other will force profitably. Keep the small ones until the spring. Besides the covering plan we have frequently lifted quantities of the roots, placing from six to eight of them in a 10 or 12-inch pot and then plunge the pot in a brisk bottom heat in a dark place. Although the growths are not so robust under this treatment as with the roots in the ground, they are earlier, and where roots are plentiful this lifting process may be practised with advantage up to the new year.

KIDNEY BEANS.—These are the most difficult of all to force in the short days; unless they can be accommodated in thoroughly heated structures their culture should not be attempted. They will only succeed in a temperature of from 68° to 75°, and at times, especially when the plants are in bloom, the atmosphere must be kept dry. A leaky house will not do for them. With a good house and plenty of heat, however, they may be grown well, and the plants will fruit in winter about ten weeks after sowing. We generally sow the seed in small 3-inch pots first, and when the plants are 4 inches high or so three of the small pots are put into a 9-inch one. They are kept near the glass and in as much light as possible. At first they do not require much water at the roots, but as soon as the pots become filled with them a little guano water is beneficial. We grow our plants on the back shelves of a Pine stove and find them succeed very well, although we can hardly say they are a paying crop, from December until March at least. Mint and Tarragon may both be forced by lifting a few roots, putting them into a shallow box, covering them with a little soil, and placing them in a temperature of 70°.

FRUIT FORCING.

FIGS.—*Early-forced Trees in Pots.*—In our last calendar we directed attention to the importance of getting the trees from which ripe fruit is to be gathered in April ready for starting in November, and if those matters have received prompt attention the plunging material has been cleared away, the roots shortened, and the turf walls rebuilt of good fresh turf with a sixth of lime rubble, and a sprinkling of crushed bones—an excellent material for the new roots to work in. The turf walls should be rammed firmly until the level of the pot is reached, when the roots that have found their way over the rim are built in, and the turf walls taken up 3 inches higher to form a receptacle for a mulching of decayed manure, and prevent liquid manure running off when the trees require water. If the trees have been infested with red spider or scale the wood-work ought to be painted, the walls scalded and afterwards limewashed. If mealy bug has got a hold turpentine should be freely used with the paint, and for dressing the trees a wineglassful of petroleum should be added to every gallon of the dressing used, and which, stirred constantly

by another person so as to keep it mixed whilst it is being applied to the trees, remembering that its potency depends in a great measure upon its thoroughness of application. Give the trees a good watering so as to have them thoroughly moist at the roots by the time arrives for closing the house in the middle of November, by which time some fermenting material should be ready, such as Oak leaves, introducing those between the pedestals, which will afford a genial bottom heat, gradually reaching the roots, producing a moist heat, saving fire heat, and lessening the necessity of syringing until the sun is getting more power. Small trees may be placed in the first instance on the surface of the fermenting bed, and when the heat declines to 75° they may be plunged; but the heat at the base of the pots ought not to exceed 75°, and instead of sinking the pots deeper as the heat declines introduce an additional supply of leaves at short intervals, until the bed is raised to the rim of the pots. This will keep the trees well up to the light—a very important matter in Fig culture.

Planted-out Trees.—Those that have been in bearing since midsummer will now be going to rest, and may be divested of the old foliage, as soon as it parts freely from the wood when touched by the hand. In the case of trees that are making too strong wood and the trees are in inside border, the present is a favourable time for root-pruning—an operation attended with the best results, especially where the space allotted to the branches is limited. Work it well under the roots, remove any inert soil, cut off all strong roots, and examine the drainage. The young or fibry roots should then be relaid in fresh compost, firmly rammed and mulched and left dry until the time arrives for starting the trees. The best soil for Figs is a good friable loam with a liberal admixture of lime rubble, broken bricks, and bone dust. Stimulants, whether in the form of solid or liquid manure, may always be given at the surface when the trees are in growth. The young shoots that have been allowed to grow up to the glass will be thickly studded with embryo fruits, which must be guarded from injury when the trees are dressed, as well as from the effects of frost, by being untied and drawn down below the trellis until the time arrives for thinning the branches that have reached the extremity of the trellis.

Late Trees.—Have all root-pruning finished, bearing in mind that strong-growing varieties, when confined to limited root space, can only be kept fruitful and manageable by limiting the rooting area, and feeding when carrying heavy crops of fruit. The houses should be freely ventilated, especially at night, except when frosts prevail.

CHERRY HOUSE.—The lights having been taken off the house, the trees are fast casting their foliage, and as soon as the leaves are all down prune at once. Cut back to within an inch of the base from whence the shoots started all those laterals which were made during the summer, and which have been stopped at about the fifth joint. It is not good practice to shorten any of the terminal shoots unless the trees have reached the extremity of the trellis, or when it is necessary to multiply the shoots another season. The trees should then be washed with a brush with soap and water, and may then have the branches tied together to save them from injury whilst the house is being cleansed and the walls limewashed. The latter should be made of the best fresh lime, put on rather thinly, and is best with a little size to make it adhere firmly. Dress the trees then with an insecticide, train and tie them to the trellis. These matters being attended to, all the loose material on the border should be cleared off, and any soil of an inert character that can be forked over and changed for fresh turfy loam of a calcareous character, or a sixth of lime rubbish may be added, then top-dress with 3 inches thickness of decayed manure. If the borders are in the least dry they must have a thorough supply of water, but the lights having been off it will be necessary only in very exceptional cases. Keep the house ventilated fully at all times excepting during frost, until such time as forcing operations are commenced, which, to have the fruit ripe at the beginning of May, will need to be at the beginning of December.

Strawberries in Pots.—Much of the success in Strawberry forcing depends upon the treatment the plants are subjected to at what is commonly known as the resting period prior to forcing. The wintering of Strawberries in pots by stacking them one upon another in sawdust or other material against a wall, or housing them on the borders of fruit houses, is not only unnecessary but absolutely injurious, as they not infrequently become dry at the roots, and the dry atmosphere induced by the free ventilation wastes the energies of the plants. Plants that have had the crowns thinned in the season, the side shoots removed and kept to a central crown, will have these well developed, having made their growth early, and have the pots filled with roots. If intended for early forcing they will be the better for heavy lights placed over them, the pots being plunged in ashes or cocoanut fibre refuse, or even tree leaves, but not so thick as to heat, but the lights must be withdrawn in mild weather, and only used in case of heavy rains, when they must be tilted, or in case of frost. They should be regularly supplied with water at the root, as the Strawberry never suffers so much as when allowed to become dry at the roots. Late plants should be placed in a raised bed or plunged in ashes or other material on the flat in a sunny position to finish the ripening process, and they too will require to be well supplied with water. Sun and sharp winds ripen the growths and solidify the crowns far better than the atmosphere of houses.

Autumn-fruiting plants should have a steady night temperature of 55° to 60°, and 10° to 15° rise by day; ventilate freely so as to prevent the condensation of moisture on the fruit, as that will cause its speedy decay.

PLANT HOUSES.

Chrysanthemums.—It is not safe to leave these outside any longer, for they are very liable to suffer from hailstorms, wind, and frost. Varie-

ties such as Princess of Teck, Princess Louise, and other dwarf plants grown for flowering after Christmas, may be left outside for a short time longer provided they are plunged in a sheltered position and protected during unfavourable weather by means of mats, tiffany, or other material. It is sometimes necessary to keep them covered by day as well as by night to insure their remaining in good condition until they are housed. When these plants are housed they should be sorted into batches, and all the late-flowering varieties arranged by themselves, so that they can be kept back as much as possible by leaving full ventilation on the house which they occupy both day and night when the weather will allow of this being done. The plants struck late in from 3 to 5-inch pots can be kept late by protection in cold frames. The lights should only be placed over them during bad weather, and if this is attended to there will be found no difficulty in keeping a good number of these dwarf useful plants for flowering during January. If there are aphides upon the plants they should be destroyed by fumigating the house with tobacco when the plants are arranged. Mildew should be watched for, and directly its appearance is observed the affected parts must be well syringed with a solution of soft soap and water in which a little sulphur has been mixed. Continue feeding the plants until they bloom. It is necessary to use a little fire heat occasionally for those developing their large flowers from crown and terminal buds, for the petals are liable to damp if due care is not taken. The house in which these are unfolding should be kept perfectly close during fogs, or the flowers will be ruined.

Imantophyllums.—These are very frequently seen with the tips of their leaves brown, which is the result of careless watering at this season of the year. If too much water is given at their roots the foliage is certain to become spotted, which destroys their beauty, for the foliage is effective even when the plants are not in flower. From the time growth ceases no more water should be given than is sufficient to keep the foliage healthy. From the present time keep them rather dry, and then the foliage will remain perfectly good. Some of the earliest plants are showing their flowers, but as these will not be wanted for some time keep them back by having the house as cool as possible.

Abutilons.—Plants in small pots for flowering during the autumn and winter should now be placed in a temperature of 50° to 55°. These must be kept slowly moving if they are to unfold a good number of their useful flowers. They should occupy a light position, and have free ventilation daily when the weather is favourable. Small plants soon cease flowering under greenhouse treatment. The plants have filled their pots with roots, and weak stimulants should be given every time water is needed.

Epiphyllums.—Keep these cool, or they will flower before they are needed. The flowers are more useful after Christmas than they are before. While under cool treatment very little water will be needed at their roots; in fact, in this position they should be kept rather dry. The roots soon perish if the soil in which they are growing is too wet while the plants are in a state of inactivity in a cold house. Plants with stems varying from 9 to 18 inches in length are very effective when in flower arranged amongst *Adiantum cuneatum*. The heads of the plants should be slightly elevated above the Ferns, which should be employed only to form a groundwork.

Luculia gratissima.—Where this beautiful flowering plant is grown in the conservatory or other comparatively cool structures it should be examined, for it is very subject to thrips. If any are present sponge the leaves with weak tobacco water. The flower trusses are advancing rapidly, and any insects that may be present must be destroyed, for it is impossible to do so when the flowers are expanded.

THE BEE-KEEPER.

THE BEST HIVE IN CREATION.

THE reason I have given the hive about to be explained the above name is that its principles have been advocated in this Journal by some, while it at the same time was as strongly condemned by others. Some of the latter, as well as many continental and transatlantic brethren, affirm it is the "best hive." Its explanation will give my reasons for saying so. Although I never made myself a prominent exhibitor I have been a successful one; almost, though not every time my hives have been exhibited, they were placed first. At the first Crystal Palace Show, though I entered some exhibits, paid the entry money, and received the receipt for the same, they were not allowed to compete. No writing could wring an explanation from the Secretary. In 1875, at the Caledonian Show, I also had several hives in competition, was unsuccessful, and some parts of my hives received severe criticism from the Judge, yet the very parts found fault with are faithfully copied by him now.

In 1876, at the Kibble Palace Botanic Gardens, Glasgow, I again competed. My hive was then awarded the first prize, but on consulting with the Judges and consideration that Mr. Abbott had come a long distance, and that he claimed properties in his hive suitable for the south, I agreed to share the honours with him. One feature my hive possessed that year was a shade. The weather previously had

been so hot that many hives' combs collapsed. This shade was raised above and around the hive by light frames of wood or wire. Pockets at each corner weighted are sufficient to prevent its being blown away. Although the Editor of the *British Bee Journal* was an eye-witness to this shade he announced a short time after that, though shade was essential, no person had up till the time of his writing suggested such a thing.

It is not through any bravado that I mention these trifles, but to impress your bee-keeping readers, particularly those of the "Cambridgeshire Bee-keeper's" type, that I am not, nor have I been, either a follower or a copyist, as some would like to make it appear. Surely I am entitled to my own. I will patent nothing nor lift my voice against those who do so honourably, but let us be all straightforward and help one another.

In describing this hive I need not set forth in detail all the advantages it possesses. Its construction will suggest to the merest tyro its advantages. There are several things bee-keepers should bear in mind—that the useful and economical hive is one that any person can make either from old or new wood, and when made it is capable of being handled with ease and moved about from one place to another. This cannot be said of many of the hives of the present day.

A free circulation of air, too, without a draught is as essential to a hive as a dwelling house. In the external appearance and construction of "the best hive in creation" and that of the cheap, thin, weather-boarded outside case lately described there is no difference. Internally there is. The outside case is suitable for any hive, octagon or square. If the octagon is used, then it will be necessary to have the doorway extending on three sides. The need of this will be explained shortly. For lightness the perforated floor will be the bottom of the case, which may be either hinged or sliding.

The case may have its posts any size, but I prefer 1½ by 2 inches, allowing 1½ inch between the wall of the case; and as it is now ceded by so many practical bee-keepers that the tiering system is the best for all purposes, we will adhere to what I have found the best size—viz., 15½ inches over the hive, or the same size and material as the Stewarton. Less in size and deeper would not be wrong, but larger superficially it must not be. The case when finished will measure about 19 inches, quite a handy size for removing to the Heather; and, owing to the lightness of the material it is made from, equally light of itself—a desirable quality. Fifteen inches and a quarter being the outside measure of the hive, must also be the exact size between the posts. Before the lining is nailed on outside the case there must be a thick rail let into the posts on the two sides just where the handles are to be screwed on; then, though very heavy, it can be lifted with safety. On the inner sides, at the junction of the lower and upper edges of the divisions of whatever number and depth they may be, a strip of wood about 2 inches broad by half an inch thick must be let in flush with the inner side of the posts. In the centre of this groove cut as much as will admit one flat of seven-eighths angled iron which forms the slide on which the hive or division runs. Before this is completed, however, it might be well to give the inner side of the lining a coat of tar. If the case is inverted when that is done none will escape to outside to injure the paint, which should be white or of a light colour. After the tar is dry pack the space between outside boarding and inner side of posts with straight straw. The door the same, which is also light, having two upright bars 2½ inches broad by five-eighths thick, to which the boards are nailed.

Underneath the door, as well as above it, there must be a strap of galvanised strong hooping both to keep it rigid, but the upper one must be portable, fixing with brass screws. This is desirable if the hive is to be practically workable. When the door of the case is open the hive proper will have the appearance of a number of drawers all having handles at the back. This hive being particularly adapted for examining any division without interfering with the other parts, and that to be done without killing bees. The entrances to all the divisions must extend the whole width, the mouthpiece of which must be a fixture between the front posts, bevelled a little on both sides, so that it may not only part with the hive easily, but that it may enter as easily into place when the division is pushed in. The slides must be put in exactly, and the divisions rather slack than tight. If the divisions are made to fill neatly and easily between the guides it does not matter, though there is a slight opening between the upper edge of a division and the underside of the angled iron slide, which is only one-eighth of an inch thick. The only opening that will affect the hive is at the back, but the opening there is filled with a little block kept at hand.

Slides are employed for sections or supers similar to those for divisions; only if small supers or sections are used a frame of angled iron must be made suitable to sizes used. This can be done cheaply. The zinc-covered roof, too, will be all the better to have the underside covered with straw, but the ventilation must not be closed. I do not consider any hive complete unless it has its crown

fitted with slides of some sort. Of these there are three kinds—the sliding as in the Stewarton, the lateral as in the Lanarkshire, and the moveable ones falling in between frames, but not close. When a hive is supplied with slides clean supers are certain, manipulation is easier, and bees are not so liable to be killed as when a quilt is used over frames with the openings between. Besides, the bee-keeper is saved much labour and annoyance in gathering, applying, and removing the propolis, always offensive and ample where quilts are so used. Frames where the dropping-in slides are used should not have broad ends, but the distance staples should be in the ends. There is one great advantage tiering hives have over broad and shallow ones—viz., the bees keep quieter during winter and do not fly out so readily in the treacherous sunshine when snow is on the ground.

I hope the foregoing notes will give an idea how to make such a hive, partly from old Orange boxes, and that bee-keepers will learn that the hive so protected with the best of non-conducting material, yet allowing a circulation of air all round, is a good one, and I hope to show that it is easy to manipulate.

To be prepared for the manipulation the bee-keeper must have a sufficient number of sheets of brown paper. These should be kept perfectly flat, and may be fastened somewhere to the door of the case, where also a few feathers should be. In the vent pocket have an exciseman's oval-shaped ink-bottle to hold carbolic acid, and another containing camphorated olive oil, very useful for reducing the pain and swelling caused by stings. Some sort of adjustable stage or platform having a division or hive similar to those inside, and on to which the inner one with bees and combs is to be drawn. If the combs are wanted free from bees slip a sheet of carbolicised paper between each seam. The bees will retreat to the box beneath, which the bee-keeper can dispose of as he has a mind. If the queen is wanted comb after comb will have to be examined separately, and when not found in the one will be in another. Sometimes the bees take a turn and seal the outside upper combs, which stops the quick and satisfactory filling of supers, as bees do not care to walk over sealed comb. When this occurs draw out the upper division and either remove the sealed combs or break the seals, then the bees will fill the supers.

As the supers rest more on the division than these do on one another, it will be advisable to wedge the supers up a little from the back, where all the manipulation is performed. This is easily done with a long screwdriver and two wedges. The hive or divisions, if exactly made, may be of the roughest description. If any think of having such a hive I doubt not but improvements will be suggested, and many more advantages will be seen than I have enumerated, but there is no other hive made that combines usefulness, control in manipulation, comfort, elegance, durability, yet lightness, and so well adapted for both bee-keepers and bees, as the "best hive in creation."—A LANARKSHIRE BEE-KEEPER.

* * All correspondence should be directed either to "THE EDITOR" or to "THE PUBLISHER." Letters addressed to Dr. Hogg or members of the staff often remain unopened unavoidably. We request that no one will write privately to any of our correspondents, as doing so subjects them to unjustifiable trouble and expense.

Correspondents should not mix up on the same sheet questions relating to Gardening and those on Bee subjects, and should never send more than two or three questions at once. All articles intended for insertion should be written on one side of the paper only. We cannot reply to questions through the post, and we do not undertake to return rejected communications.

Pansy (G. H. B.).—The flower did not arrive in a sufficiently fresh state for its merits to be satisfactorily determined; but it appears to be a very good variety.

Lecture on Fruit Trees (Gardner).—Mr. Baillie's lecture was published in this Journal, and we are not aware that it has appeared in any other form. As you are a reader of the Journal you will possess the lecture if you have preserved the numbers, and if you have not, we think the publisher can supply them.

Bulbs Decaying (J. H. S.).—The bulbs appear to be attacked with a small mite that is very destructive to Eucharis bulbs. You had better burn the worst examples and wash the remainder in a solution of Gishurst compound before potting or planting them. They should be well surrounded with sand or sharp ashes.

Pears Cracking (H. S. E.).—The cracking is due to the light sandy or gravelly soil, and the variety, which seems to be some late sort which we cannot name, is not likely ever to succeed. Graft the tree with such as Doyenné du Comice, Vau Mons Leon Leclerc, or Beurré Superfin.

Erythras and Tigridias (Somerset).—The height referred to is that of the tree in the Brazilian forests. All the varieties you name grow about the same height when planted close to a south wall in this country. The stems are cut down in winter, and if ashes are placed over the roots fresh growths appear in spring and flower when they attain a height of 3 to 5 feet according to the nature of the soil. The growths are usually trained to walls, but in sheltered places in some of the London parks the plants grow and flower in open beds, the plants in that case being wintered in pots. If your plants are established near a warm wall to which you wish to train the growths we should not disturb the roots, but afford protection in the manner indicated. If your garden is much exposed there is no certainty of these plants flowering in the open, and you had better try the species you have in that way before purchasing the others. For producing a good mass Tigridia bulbs should be planted not less than 6 inches apart. They should be inserted during a fine day in spring, when the soil is in free good working condition.

Liliums (A Subscriber).—You had better turn out the bulbs, removing most of the old soil from them with any dead roots above or below the bulbs, but not disturbing the large fleshy roots that you ought to find, and place them at once in fresh soil. They grow well in equal parts of turfy loam, peat, and leaf mould, adding sand and crushed charcoal to render the whole porous. Place sand round the bulbs, and do not fill the pots with soil, but leave space of an inch or two for top-dressings. If the soil is pleasantly moist, as it should be, not decidedly wet, nor so dry that it escapes between your fingers when a handful is grasped, no water will be needed, provided the pots are plunged in damp cocoa-nut fibre refuse or ashes and covered with the same 3 or 4 inches deep. A cold frame is a good position for them during the winter and the earlier stages of growth in the spring.

Size of Chrysanthemums (A. B.).—Your bloom of Queen of England, 24 inches in circumference, is, if solid, above the average size of flowers of this variety staged at the London shows, and Lord Alcester, 18 inches in circumference, is not often seen larger when cupped and arranged in the stands. Good judges have regard to the depth and solidity of blooms, and do not look with favour on what they term "blown out" examples. We do not for a moment suggest that yours are of this character, and if they are deep, firm, and fresh, they are large enough for staging anywhere.

Angle for Cordon Trees—Gishurst Compound (F. J.).—For getting the "best value out of the space" the trees should be trained at an angle of 45°, but not when first planted. They may be vertical, or only slightly depressed the first year for encouraging growth, then gradually brought down to the angle indicated. Any that do not grow freely may be kept upright, others that grow robustly may be depressed, and in this way your wall may be uniformly covered in the course of a few years. A strong lather of Gishurst compound is excellent for brushing into the crevices of fruit tree branches in winter for the destruction of insects. We have never said it will cure canker, but is at least worth trying, and if it fails it is certain softsoap will not succeed in accomplishing that desideratum.

Moss Roses—Primulas (W. A.).—You have not made the condition of the Roses clear to us. There are numbers 3 feet high, yet the growth they make annually is weak and poor, while others of the same height have luxuriant shoots. The length and strength of the wood made in the summer is what must be known before anyone can properly tell you how to prune and treat them. If the pots of your Primulas are filled with roots give them clear soot water of the colour of pale ale about twice a week, and let them have a light position in a house having a temperature ranging from 45° to 55°. We are not aware that you can safely push them in any other manner, unless you like to try a little sulphate of ammonia, about a quarter of an ounce being dissolved in a gallon of water.

Drying Pampas Grass (South Norwood).—The best and only plan that we know is to cut the plumes with a good length of stalk when quite dry, and before the plumes are quite clear of the sheaths, placing them in a greenhouse or other place where they will be dry, in a similar position as grown, or upright. In ten days to a fortnight they should have the leaves or grass removed and given a gentle shake; they will then open out, and have the beautiful feathery appearance for which they are so much admired. Ours dried in this way retain their beauty for at least twelve months, indeed we have some two years old still very attractive.

Temperature for Ripe Grapes (Merchant).—The temperature for Black Hamburgs and Alicante Grapes, now they are ripe and the leaves falling, should be kept as equally as possible at 50° by artificial means, with ventilation in the daytime, so as to allow of damp escaping, the pipes being allowed to cool before night, and even then a little top air may be given so as to prevent the deposition of moisture on the berries through the night. The temperature at night should not fall below 45°. Do not allow the temperature to rise in the morning over 50° without giving a little air, or moisture will be condensed on the berries, and they will not keep well. The Muscat will not now colour well, but we should afford a temperature by day of 60° to 65° by artificial means, and ventilate freely above that temperature, indeed allow a little air with a gentle warmth in the pipes constantly until the leaves turn yellow, when the temperature may be lowered to 50° gradually, ventilating freely by day in favourable weather. We think the Vines are in good condition, and the promise for another year excellent. You may apply a dressing of quicklime to the border, and point it in with a fork, but not so deeply as to injure the roots. Half a bushel per rod (30½ square yards) of border would in your case be amply sufficient.

Preserving Labels—Impatiens Sultani (Trike).—We know of no better method of rendering wood labels used in flower pots more enduring than that suggested a few years ago by Mr. G. F. Wilson—namely, soaking them in hot paraffin. Some that Mr. Wilson had soaked for forty-eight hours absorbed 12 per cent. of the paraffin. You probably know that paraffin is not petroleum, but a solid substance, and it contains nothing injurious to plants; but if you cannot readily obtain it you may try soaking the labels in petroleum, which is a preservative of wood. You may insert cuttings of

the Impatiens now, and they will be well rooted in a week in a brisk temperature. After young plants are established the old can be thrown away if you have not room for them. If you have no propagating case insert one cutting in the centre of a thumb pot of sandy soil, and as many more as you like in the same way, placing the pots in a box, which cover closely with squares of glass; stand the box in a warm position in your plant stove, and we think you will succeed. Your other letter shall have attention.

Mealy Bug in Vineries (J. L. A.).—Stronger remedies are safely employed by experienced gardeners than can be safely recommended to less experienced amateurs. Mr. Divers is a very able, also a very careful man, and it is certain he would not have described his practice on page 288 (October 1st) if he had not found the strong remedies he adopted perfectly safe. We have seen the mixture of tar and clay applied to numbers of rods by various gardeners with perfect safety, but have not had occasion to use it, as our Vines are clean. We have never seen such a strong mixture of petroleum and carbolic acid applied to Vines as mentioned by Mr. Divers, and we suspect he would have achieved his object by using less quantities. The reply given on page 371 is founded on practical experience, and the method there described of cleansing Vines and vineries has proved successful. It is very important that the Vines be examined daily as they are coming in leaf, and every insect destroyed. This may be done, as was stated, with a small brush and methylated spirits. Just as the buds are swelling, the rods—not the buds—may be dressed with petroleum, mixing a wineglassful in a gallon of water in which 2 ozs of softsoap is dissolved. Comparatively mild remedies thoroughly applied are as effectual as stronger applications not so carefully given. Every part of the house must be cleansed with the same care as the Vines.

Renovating Vines (J. F. H.).—The Vines are evidently in poor condition, the roots perhaps deep and in an unfavourable rooting medium. We should remove the surface soil down to the roots and pick out as much of it as possible from amongst them carefully, and if the roots are deep—more than a foot from the surface—they should be carefully lifted and placed in fresh soil nearer the surface; but if they are not deep, then only proceed as above advised, and in place of the soil removed from amongst the roots add a compost of fresh turfy loam, with a tenth part of old mortar and a twentieth of crushed or half-inch bones and charcoal in equal proportions, the turf chopped up moderately small, and the whole thoroughly incorporated. Work it well in amongst the roots with the hand, and then cover them 6 inches deep with the same kind of compost, and mulch the surface 6 inches thick with rather short fresh stable litter, which will protect the roots from frost and encourage surface fibres. No manure should be mixed with the soil, but what is required in the way of stimulants should be given at the surface as mulching and liquid manure during growth. The quantity per Vine will depend upon its size, but in ordinary cases a distance of 12 feet from the stem outwards is treated as suggested. The best time to perform the work is now, doing it in mild weather, and having all in readiness so as to do it quickly, keeping the roots as little exposed to the atmosphere as possible.

Hardy Rose-coloured Nymphaeas (G. G.).—We cannot better answer your question than by citing from a letter that was communicated to us last year by a great authority on and successful cultivator of aquatic plants:—Questions are from time to time asked regarding the hardiness of the rose-coloured variety of our common Water Lily, and also the variety rubra of *N. odorata*, not only north of the Tweed, but many lovers of the beautiful aquatics in the south are not at all sanguine of its success outside. That they are hardy enough even far north there can be no doubt, sufficient time having elapsed since their first introduction into cultivation in our gardens; and where the anxiety to have them has overcome the doubt of their hardiness they have surpassed all hopes, and within the last half-dozen years their capacity for standing even the hardest winters has been thoroughly tested. With them, however, as with many other aquatics that adapt themselves to our trying climate, planting near the surface of the water should in all cases be avoided—from 2½ feet to 1½ foot at the very least being about the depth usually recommended, as deep planting not only serves to protect the crowns from frost were they likely to be injured, but it also serves as an inducement to freer flowering. *Nymphaea alba* var. *rosea*, which is confined to Sweden, was first introduced into this country about the year 1872, and since that time has been cultivated with success in several places where aquatic plants are a speciality; indeed, wherever the *N. odorata*, *N. tuberosa*, and *N. alba* can be grown there will be no trouble with the rose-coloured variety in question. Of *N. odorata* var. *rubra* much the same may be said, and as they both form quite a novelty in the way of hardy aquatics, we may yet hope to see our lakes made beautiful with a colour that unfortunately has been too long associated with glass houses and hot-water tanks. In the matter of soil they are not fastidious. Strong loam, to which has been added a good half of cow manure and rough sand, will be found a good mixture in which to grow them; and, instead of lifting or disturbing the plant when fully established, preference may be given to a good top-dressing for the first two or three years, or until a failing is detected. The other plants that would no doubt flourish in your tank are *Aponageton distachyon* and *Menyanthes trifoliata*. The Water Flag, *Iris pseud-acorus*, would also succeed.

Names of Fruits.—The names and addresses of senders of fruit to be named must in all cases be enclosed with the specimens, whether letters referring to the fruit are sent by post or not. The names are not necessarily required for publication, initials sufficing for that. (*N. H. Pownall*).—Suffolk Thorn. (*J. D.*).—1, Reinette de Canada; 2, Scarlet Nonpareil; 3, Sam Young; 4, Dutch Mignonne; 5, not known; 6, Beurré Langelier. (*C. E.*).—1, Gansel's Bergamot; 2, Doyenné du Comice, (*S. T.*).—1, Pearson's Plate; 2, Golden Pearmain; 3, Paradise Pippin; 5, Emperor Alexander; 6, Northern Greening. (*E. M.*).—1, Hollandbury; 2, Lane's Prince Albert; 3, Golden Reinette; 4, Lewis' Incomparable (?); 5, Sturmer Pippin. The Walnut is the Thin shelled. (*A. W.*).—1, Dumelow's Seedling; 2, Yorkshire Greening; 3, Hall Door; 5, Court Pendu Plat; 6, Braddick's Nonpareil. (*J. K.*).—1, Reinette de Canada; 2, Rosemary Russet; 3, Catshead; 4, Golden Noble; 5, Small's Admirable; 6, Yellow Ingestrie. (*S. T. Clothier*).—1, Brown Beurré; 2, Napoléon; 3, Easter Beurré; 4, Bergamotte Esperen; 5, Vicar of Winkfield. (*W., Reading*).—1, Golden Pearmain; 2, Golden Noble; 3, Dutch Codlin; 4, Caraway

Russet; 5, not known. (*A. Brooke*).—1, Beurré d'Aremberg; 2, Beurré Diel; 3, Passe Colmar; 5, Hacon's Incomparable; 6, Crassane; 7, Glou Morceau. (*F. P., Exeter*).—1, Hughes' Golden Pippin; 2, Ribston Pippin; 3, Cellini; 4, Mère de Ménage; 5, Gilgil. (*W. W. W.*).—1, Franklin's Golden Pippin; 2, London Pippin; 3, Cellini; 4, English Codlin; 5, Keswick Codlin; 6, Claygate Pearmain.

Names of Plants.—We only undertake to name species of plants, not varieties that have originated from seed and termed florists' flowers. Flowering specimens are necessary of flowering plants, and Fern fronds should bear spores. Specimens should arrive in a fresh state in firm boxes. Slightly damp moss or soft green leaves form the best packing, dry cotton wool the worst. Not more than six specimens can be named at once. (*A. H. P.*).—*Cercasus borealis*. (*Rosa*).—1, *Ipomœa palmata*; 2, Impossible to name: send larger specimen with flower; 3, *Clematis brachiata*; 4, *Bryophyllum calycinum*.

COVENT GARDEN MARKET.—OCTOBER 28TH.

BUSINESS is quiet, early Apples being now cleared. Kent Cobs free at same rates.

WINTER DIET.

AGAIN has the time come round for bringing dairy cows and cattle into yards off the pastures, and well will it be now before it is too late if we carefully consider ways and means, and see if our provision of food for winter is ample for feeding all the live stock we intend keeping till we are able to turn them out upon the grass again. In doing this we ought to allow a full margin for a late spring, which really means that we should now have enough food laid up in store or upon the land for the next seven months. To those who were so unwise as not to do this last autumn came a severe trial in spring, when, instead of being able to turn out the cattle upon the grass early in March, they had to buy food week after week till late in May. It is true enough that many a man did turn out his cows in April, but to very little purpose, for the pastures were generally bare where this was done; yet many a meadow even then gave pleasing indications of the heavy crop of hay which was saved in such excellent condition when summer did come. Paradoxical as this statement may appear, yet it is true enough. The man whose store of fodder and roots was exhausted prematurely was in most cases the man whose poverty-stricken pastures made little progress till late in spring, while he whose forethought had led him to make due provision to meet the fluctuations of our uncertain climate, had taken good care to impart fertility to his pastures by the timely application of manure. We have repeatedly told how this restoration of fertility, or rather this prevention of exhaustion in pastures, is managed, and we hope to do so again at the proper season. But even in winter the difference between rich and poor pasture is too remarkable to escape attention. We must not, however,

debate on this matter now, important though it be, but we will keep to the point of our lesson—the quantity of food we have in store, the number of animals for which food has to be found during winter.

Dairy cows must not only be kept, but they must have a liberal diet; therefore we must give them first place. Next to them come any beasts which we design either for Christmas beef or to have ready for the butchers at a given time in the three months after Christmas. Next come heifers and cow calves reserved as future additions to the dairy herd. We cannot well dispense with them, but if, after we have made sure of having enough food for the whole of them, there is the slightest prospect of running short, we must have no hesitation as to the immediate disposal of any other calves or store cattle we may have. The price is undoubtedly so low now as to make one slow to sell, a yearling being hardly worth so much as a calf was a year or two ago. We have recently seen yearlings in fair condition sold for £5 10s. apiece; yet we cannot hope to gain any profit upon keeping superfluous stock till spring. It has never answered to let any cattle fall into poor condition in winter, and we again say, Keep well within the scope of your means in this matter, and let what you do be done in the best way. In making calculations take care that there is abundance of wholesome food and pure water, in addition to warm, snug, yet spacious quarters, dry bedding, and sound sheltered yards. By sound yards we mean yards with firm raised bottoms and efficient drains, so that there is no danger of any harmful accumulation of water.

Sheep must also be taken fully into account, for notwithstanding recent low prices the flock still brings in the nimble 9d. of profit under skilful management. We must have chaff of both straw and hay, with crushed Oats and bran of dry food, with plenty of Cabbage and grass up till lambing time, when—or a little sooner—Mangolds come fully into use, and Turnips are held in reserve later on for the breeding flocks, but hoggets will be put upon them at any time. Do not in any case reckon upon Turnips for the breeding flock till after lambing; many serious losses by abortion have happened solely through folding the ewes upon Turnips. By all means keep ewes in lamb in good condition now and onwards throughout winter if you would have a healthy strong crop of lambs. Our safety crops for spring feeding of the flock are almost all sown, but it is not too late to sow Winter Tares for a supply of green food next May, and we strongly advise those who feel doubtful of their provision of food for that critical period of the year to lose no time in sowing a large breadth of them. We have had a few acres of Mangolds pulled somewhat early specially to clear the ground for another piece of Winter Tares. Our bailiff said it had always been customary upon that farm to put sheep upon the Mangold ground when cleared of roots to eat the leaves, but we would not allow this to be done, knowing as we do what an excellent supply of manure the leaves impart to the soil when ploughed in quickly. In the field next to where the Mangold was so cleared off we have eleven acres of Rye nicely above ground, a strong thick sturdy plant. This green crop is after Barley, and no manure was used for it at the time of sowing; but next February we purpose giving it a hundredweight of nitrate of soda per acre.

(To be continued.)

WORK ON THE HOME FARM.

Calves and colts should now be confined to the yards and lodges to keep them from exposure to cold and wet, and to protect calves from hoose, which is so often rampant among them in autumn. The larva is picked up by them from the coarse herbage which comes in wet undrained land, or from foul water in stagnant pools, and develops in the animal into thread-like worms from 1 to 2 inches in length. These worms are sometimes found in masses in the throat, causing a cough which proves fatal in many a case. The remedy is two or three inhalations of sulphur fumes; but do not forget that prevention is better than cure, for if once this disease get strongly hold of an animal it causes much debility. The sowing of winter corn and the application of artificial manure goes steadily on as weather permits. See that all sloping land has enough water furrows to check any serious surface washing by heavy rainfall.

Every effort must be made to get in the Wheat as soon as possible. In very wet districts it is safe practice to plough and sow day by day, for if we plough and wait for fine weather for sowing, we may have long to wait at this season of the year. Do not let Mangolds remain out in the fields any longer. No more growth can reasonably be expected now, and much harm may be done by early frosts. Do not forget that Mangolds may be used at once with perfect safety if pulped, mixed with chaff, and allowed to undergo a slight degree of fermentation before being used. Much Barley was laid and discoloured. Some of the grain, too, is slight, owing to drought. We should refrain from pressing the sale of such, or of any inferior corn, but rather hold it in reserve for crushing or grinding for animal food. Barley meal for pigs, and oatmeal for both pigs and poultry, is excellent food, and there should be no waste upon a farm, nor need there be any sacrifice of corn at extremely low prices. Pigs that have been out on the stubbles may now be disposed of at once for porkers, or brought on quickly for bacon. We have no faith in a low diet for swine, but prefer to bring them on quickly batch after batch, and we have several yards full of them now to consume inferior corn and to make some manure for our root crops next summer. We have so often found some farmyard manure insure success in root culture, especially in seasons of drought, that we do not like to dispense with it altogether for such crops.

DRAINING.

THIS is the time of the year when landowners undertake draining operations, and, if I may be allowed to speak from experience of most English counties, those operations will be conducted in a wrong because not a thorough manner.

The usual way of draining a field is to cut a trench about 3 feet deep, put in some 2-inch pipes, fill in the stiff clay again, and thus ends the matter. In a few years the pipes are choked up, or rather do not act, the truth being that they are choked up in a few months by the loose soil from above, but there is a certain amount of good effected by them until the soil that was turned back upon them becomes homogeneous once more; then of course drainage is at an end.

Now, the only lasting and efficient cure for bad drainage is not to turn back the clay upon the drain pipes, but to burn that clay into ballast, and put back the ballast upon the pipes. Ballast is both hard and porous; rain trickles slowly but surely through it down to the pipes, and thus, instead of the drain being merely 2 inches in width when the job is done, that drain is at once increased to a practicable depth of 3 feet with a 2-inch fair outlet all along its base. Such a drain can never become stopped.

To burn clay to ballast is very inexpensive—not more than a shilling per cubic yard of clay. It expands 25 per cent. in burning. The ballast heap when cold should be raked down, so as to avoid using the fine stuff. This fine stuff is rich in soluble potash, and the very best of manures for Potatoes. In fact, in many cases the manurial value of the superfluous ballast would pay the expense of burning it.

If any of your readers desire information how to burn clay into ballast I shall be happy to inform them, or, if you think fit, to describe the process in your columns.—W. M.

[Practical notes on this important subject could not fail to be acceptable to many readers.]

OUR LETTER BOX.

Grain (F. S.).—The Tare seeds had escaped from the packet and fell out of the envelope in opening the letter. The Barley is only a moderate sample. It is contrary to our practice to recommend dealers. Farm seeds can be had in all markets that are largely attended by agriculturists.

REMARKS.

18th.—Dull and rather raw.
19th.—Fair generally.
20th.—Fine bright day.
21st.—Foggy till 11 A.M., then fine till 3 P.M., afterwards thick with slight rain.
22nd.—Fine early, cloudy day, moonlight night.
23rd.—Dull early, very wet after 10 A.M., and all night.
24th.—Rain early, fine and bright about 10 A.M., then windy, dull, and showery, but not measurable.
Rather damper and cooler than the previous week, and with less sunshine. The mean maximum temperature continues its unbroken decrease, which this week amounts to 2°.—G. J. SYMONS.

FRUIT TREES—PRUNING AND LIFTING.

THE work of pruning, nailing, and root-pruning fruit trees is often, if not generally, postponed till winter, but no more unsuitable period could be selected for such work. It is unsuitable because the individuals engaged in it are exposed to the risk of catching severe colds and probably rheumatism. Economically it is not the best season, for the days are comparatively short then, and a man cannot accomplish one-fourth the work during piercingly cold days that he can when the weather is genial. We should also remember the beneficial effect early pruning has upon fruit trees. When the trees are pruned directly, all fear of their starting again into growth is past; every ray of light and sunshine has free access to the wood and fruit spurs, and assists in the important work of maturation which is so essential to the production of good crops of fruit. Early pruning is further beneficial because it results in the resources of the trees being spent in completing the full development of the buds instead of being conveyed into wood that has to be cut away.

The general autumn and winter work is considerably advanced by completing pruning and nailing by the time the foliage falls, if it cannot be accomplished earlier. This allows of the necessary manuring and digging being brought to a close as early as possible. When fruit gardens are in close proximity to the houses or other frequented parts, it is important that the vacant ground between the trees should be made neat as early in the season as practicable. It is useless to turn over walks or regravell them until this work is completed, and when pruning is left until the winter this department is untidy for some months longer than need be the case.

Nearly the whole of our fruit trees are pruned, and every advantage is taken to complete the nailing as rapidly as possible. The ground where the bush fruits are grown is ready for manuring and forking over, deep digging being avoided. After the Raspberries were gathered the old canes were removed, as well as all that were not required for next year's fruit-bearing, those retained being secured to thin supports, and the only work remaining to be done is that of shortening the canes and wheeling on manure; the former will be done before these notes are printed, and probably the latter also. Gooseberries have been pruned some time by merely removing branches that are likely to hang upon the ground; also strong useless wood or any shoots that crowd or render the bushes unshapely. Hard pruning is unnecessary, and a crop of fruit is certain by the system of pinching the shoots while young, as advocated during the growing season.

It was then asked how the buds were preserved from the birds and the foliage from being devoured by caterpillars. Both questions in my case are easily answered, the first by placing a net over the trees directly the ground has been forked, or we should get no fruit. This necessitates the trees being planted as much together as possible. The Gooseberry is well worthy of this protection where birds are troublesome,

and in the end it is the cheapest and most effectual manner of preserving the buds. Some years ago caterpillars were very prevalent; they were destroyed by syringing the trees with a solution of hellebore, and since then every moth that made its appearance was caught, and we have never been troubled with caterpillars since. Apples and Pears were pruned as soon as the fruit was gathered; in fact, all the work will be completed by the end of next week, except a few standard trees and a wall of Morello Cherries.

If due attention is paid to thinning and pruning during the summer, very little remains to be done during the autumn months. Many of the shoots on both Apples and Pears that were pinched early in the season have formed splendid fruit buds instead of extending into growth. This renders autumn pruning a mere matter of shortening leading shoots, thinning out weak growths likely to crowd the trees and those that started after the second pinching. Fruit buds cannot be induced to form on the young wood of trees subjected to hard pruning in winter, but luxuriant growth is promoted, and this does not ripen sufficiently in the majority of seasons to produce fruit spurs on the young wood.

Trees that form fruit spurs on the young wood after being pinched early in the season are generally well managed, and almost certain to carry crops of good fruit if the weather during the flowering period is favourable. Severe frost will certainly destroy the strongest and best developed flowers, however well ripened the wood may be; but if the flowers are set they will bear a good deal of cold before the young fruits are destroyed. This was proved last spring, for certain varieties of Pears were just set and subjected to 8° of frost, yet they bore large crops of fruit, but all in flower along the same wall were practically barren. I believe a piece of tiffany hung in front of the wall that one night would have saved the blossom. The result, however, is that we have only had a partial crop. Horizontally trained trees running east and west have scarcely a fruit upon them. Several pyramidal trees bore only on the east and west side. This clearly proves that in our case, at least, the sun did its share in the work of destruction. In future trees exposed to a sharp frost while in bloom will as far as practicable be screened from the sun the day following the frost, with mats or any similar material.

But, to return to our subject. The lifting of fruit trees in order to root-prune them, plays as large a part in promoting their fertility as pruning does. Trees that are not root-pruned often make an enormous quantity of wood, and rarely bear good crops of fruit, but often fall a prey to canker. In order to keep fruit trees healthy, and in the best condition for bearing fine fruits annually, they must be subjected to periodical liftings of their roots. With disbudding early in the season, summer-pinching when necessary, and a careful system of root-pruning, the knife is scarcely needed in their management except, perhaps, to thin out the fruit spurs that, with age, have a tendency to become crowded.

In a properly managed fruit garden there are always some trees that need root-pruning, and it is much better to lift them as needed than to wait until a good number require attention. When the trees that require lifting are done as they become ready this operation does not prove a very laborious one, and the whole of the trees are retained in a healthy fertile state. Directly a tree shows signs of growing too strongly a trench should be cut at a suitable distance from the stem and the strongest roots shortened. While the trench is open it should be ascertained if any roots are extending in a downward direction, and if so they should be removed. When trees possess a large quantity of fibry roots, which is generally the case when subjected to a judicious system of lifting, the trench cut round the tree will often prove sufficient to check its growth without disturbing the ball to any great extent. Those with plenty of fibry roots make short sturdy growths, and these form quantities of flower buds the same season. It is often necessary to cut

these hard back in order to keep growth in the trees, and be certain that they are sufficiently vigorous to swell their fruits to a large size. It is undoubtedly a mistake to get the trees in such a fertile state that they produce annually nothing but fruit spurs. They must not by an unduly severe system of root-pruning be crippled. It is as necessary for the trees to produce every season a moderate amount of wood as it is for them to have fruit spurs for the production of fruit. Stunted trees may be renovated by lifting their roots and the removal of the fruit for a season or part of the crop. When these trees are lifted a few barrowfuls of good loam, with some half-inch bones and a little soot or wood ashes mixed with it, should be laid amongst the roots. This in a season or two invigorates the trees and works wonders in bringing them back to health and vigour. Freedom from fruit-bearing alone for one season has a wonderful effect upon such trees.

Where practicable all trees that are lifted should have a good mulching of manure as far round the stem as the roots extend. On light shallow soil we have found it a good plan to mulch all fruit trees annually. Root-pruning may be done any time during the autumn, and we have always found that the earlier it is completed the better. When lifted before the foliage falls the trees make a fair quantity of roots before winter, and start into growth the following season with greater freedom.—WM. BARDNEY.

THE PRIMULAS.

(Continued from page 357.)

P. DENTIFLORA, And.—I have never seen this in cultivation, although I hope it will arrive one day from some of the old gardens. It resembles *P. cortusoides*, and were it not for the very distinctly serrated petals might be mistaken for a form of that species; the above character, however, which is said to be constant, is considered by many to be a good specific distinction. It has also the recommendation of flowering during the month of September, which should be enough for all growers of hardy plants. It grows about a foot in height, with a straight stem carrying from twelve to eighteen deep purple yellow-eyed flowers in a loose corymbose head. The leaves are the same shape, and not unlike *P. cortusoides*, not rough however, and not so deeply dentate. Syn., *P. cortusoides*, var., *Lehm*; *P. dentata*, *Don*.

P. DIGNEA, A. Kern.—A hybrid between *P. elatior* × *acaulis*; *Reut*, more interesting than beautiful, and not by any means a desirable garden plant.

P. DINYANA, *Lagget* (*P. super-integrifolia* × *viscosa*, Kern).—Closely allied to *P. Muretiana*, another hybrid, which is sub instead of *super-integrifolia*. *P. Dinyana* is a first-rate garden plant, growing with freedom even on the border, and never failing with a plentiful crop of its cheering flowers. It, however, requires well-drained soil, and is all the better of a few stones packed round the neck of the plants, as it is inclined to get leggy. The leaves grow about 4 inches long, curving down from the crown. They are ovate lanceolate, with ciliated and distantly dentated margins. The scape is from 3 to 6 inches high, terminated by about half a dozen lovely deep purple flowers, produced in April and May. Native of Bavaria.

P. DISCOLOR, *Leyb.* (*P. super-auricula* × *daonensis*, Kern).—A very beautiful plant from the West and South Tyrolean Alps, where it is found in the fissures of the granitic rocks at elevations of 6500 to 7000 and 8000 feet above the sea. It is amongst the easiest of this section to grow when in its element, granite. We manage it by tightly wedging the fleshy roots between the rough pieces; and as it seems to prefer an almost perpendicular position, care should be taken that it does not want for water, and especially during the time it is making its growth. The habit of the plant is more in the way of *P. Auricula* than *daonensis*, as also are the leaves. They are nearly ovate, very slightly dentated at the margins, and sparingly covered with glandular hairs. The petioles are leafy, broadening to the clasping point. Flowers large for the size of the plant, lilac or violet purple, very striking and beautiful. It flowers during April.

P. DUMOULINII, *Stein.*—A hybrid between *P. subminima* and *spectabilis*, *Stein.* This plant is nearly related to *P. minima*, the chief difference between them being in the shape of the leaves, the great number of flowers borne on short sturdy stalks, and the much deeper colour. On the mountain Trate in Indicien there seems to be a great variety of forms, the result of crosses between the

above two species, some of which approach *spectabilis* and others *Fachinii* and *minima*. *P. Dumoulinii* forms pretty little tufts of jagged-edged rosettes, from which rise the numerous flower stalks, bearing each many flowers, and which if it were as plentiful would make it more preferable than *P. minima*. It thrives well on limestone, and seems to like a fully exposed situation. It flowered with us in April.

It was named in honour of Count Carl Dumoulin of Bertolshelm, a Bavarian botanist of repute.

P. ELLIPTICA, *Royle* (fig. 61).—Introduced a few years ago by the late Anderson Henry, Esq., Edinburgh, and sent out by him under the name of *P. obtusiloba*, a name by which a form of *P. involucrata* has also been distributed, probably through some mistake in labelling the seed sent home. It grows well in the north, the home for Himalayan plants generally, but proves delicate in the south of England; indeed it often dies after it has flowered, as so many plants from that region do in our hot dry summers. It may be described as a *Primula rosea* with bluish purple instead of rosy red flowers. The leaves are not at all mealy, about 2 inches long, ovate or ovate oblong, narrowing into a broadish petiole, the margins sharply toothed, and the upper surface dark green and shiny. It

Fig. 61.—*Primula elliptica* (after Royle).

grows between 6 inches and a foot high, with from four to ten flowers in a loose umbellate head surrounded at the base by narrow bracts. The flowers are purple or almost blue, with broad deeply cleft lobes, and having an extremely variable tube. It is found at elevations at 8000 to 12,000 feet above the sea in Western Thibet, Peer, Punjab, Cashmere, &c., flowering in June and July. In peaty soil in shady positions. Syn., *P. denticulata*, *Wight*; *P. spatulacea*, *Jacquin's MSS.*

P. EROSA, *Wall.*—Though quoted by Duby in De Candolle's "Prodromus" as a variety of *denticulata*, this has by modern botanists been thought quite deserving a specific distinction, and it is so given in the "Flora of British India." In aspect it is not unlike *P. denticulata*, and may readily be taken for a small form of that plant. It requires similar treatment, a partly shady spot on the rockery in peaty soil suiting its requirements well. The flower stems grow from 4 to 8 inches in height, supporting an umbellate head of lavender or purple flowers covered with fine meal dust. The leaves are fully developed with the flowers, oblong spatulate or oblanceolate, coarsely or unevenly toothed, the edges appearing as if partly eaten away. They are generally a few inches long, but sometimes attaining the enormous length of 18 inches and entirely free from meal. It flowers in early spring. Native of the districts from Kumaon to Bhotan in the Himalayas, at elevations of 4500 to 9500 feet above sea level. Syn., *P. denticulata* var. *erosa*, *Duby*.

P. FACCHINII, *Schott.*—The author named considers this to be a cross between *P. minima* × *P. spectabilis*, and by Stein to be *subminima* × *spectabilis*. The latter I am inclined to favour, as the form in cultivation in this country has decidedly more of *minima* in it than of *spectabilis*. Schott in Reichenbach's "Flora" gives it a distinct place, while Nyman ("Conspectus Europæa") reduces

it to a variety of *Floerkeana*, *Schrad.*, which is no doubt its right place. It seems a variable plant; in some of the forms the leaves deeply and sharply crenated, while in others the crenations are hardly distinct, showing how little reliance can be placed on mere leaf characters when the plant has a wide distribution. It grows 2 or 3 inches high, the sturdy scapes supporting two or three fine rosy purple flowers, about an inch in diameter. The leaves are spatulate, gracefully curved, deeply crenated, and forming a compact little rosette. It grows best in a loose well-drained soil, lime predominating, and wedged between pieces of limestone. It likes plenty of sun and light. Native of the Tyrol and granitic Alps on east and west exposures, flowering in May and June.—D.

(To be continued.)

ESTIMATES OF VEGETABLES.

KIDNEY AND RUNNER BEANS.

THESE are of two kinds—viz., the Dwarf or French, and Runners. I was told the former did not pay, being next to unsaleable, and that the latter would only bring in a plentiful season 1s. 6d. per bushel. This I thought a poor affair if true, especially as they were quoted at 3d. to 4d. retail in the list of Covent Garden Market prices as given in the gardening papers, and as I sell wholesale, or rather the Covent Garden salesmen do for me, I entered on their cultivation with great misgivings as to the result. However, I resolved to put matters to the test, finding a season's experience of more value than a lifetime of hearsay information. My first consignment of French Beans realised 1s. per lb. on July 11th; on the 18th the price fell to 6d., 4d. on the 21st, and on August 1st the value per half-sieve of 16 lbs. had fallen to 1s. Scarlet Runners brought 1s. 1d. per half-sieve of 16 lbs. on August 1st, and on August 4th French Beans brought 2s. per bushel of 32 lbs.; and on August 8th Scarlet Runners sold for 1s. 6d. per bushel. Between this and autumn the prices fluctuated from 3s. to 4s. per bushel; the last sold October 17th, bringing 2s. 6d. per half-sieve of 16 lbs.

Then I was told that Runners yielded best when treated as dwarfs—i.e., stopped and not staked, which might have been another stumblingblock, only I did not care to see it, as I had determined to have half an acre, and meant to stake half and stop the others, leaving them all the same distance apart, or 5 feet, with a row of French Beans between the rows of the Runners intended to be stopped. The results were that the Runners pinched afforded pods fit to gather ten days earlier than those staked, and everything looked in their favour, but the staked Runners gave twice as many pods row for row as the stopped ones, and the quality was much superior. This was only what might have been expected, as the stopping concentrated the strength of the plants on the first fruits, and they in consequence swelled and came to maturity—i.e., use, ten days in advance of those running up stakes, which were making unchecked growth, and with a better hold of the soil they were enabled to give a better crop, though somewhat later; but the advantage of earliness in the stopped is counterbalanced by their being sooner affected by drought, and in the liability to be cut off by the early autumn frosts whilst the staked ones escape, consequently affording a much later supply. Our stopped Runners were cut by the frosts that occurred at the end of September, whilst the staked rows were not injured and gave Beans fully a fortnight later.

For early use I find Osborn's Forcing excellent, but I do not care to grow many of it as its pod is small in comparison with those that come in a little later, and it is fine appearance with good quality that bring the best returns from the salesman. Of Dwarf or French Beans I award the palm to Ne Plus Ultra, of dwarf habit, a great cropper, with fine straight pods, and good colour. Equally good, but a stronger grower is Negro Mammoth Long-podded, a great advance upon the old Negro, having pods twice as long and giving quite as many of them. It is a really good variety, and has not the purple tint on its pods to the same extent as the old sort. Canadian Wonder also deserves praise in common with the other two, and comes in a little later, being stronger in growth than Negro Mammoth, is a very fine-podded variety and heavy cropper. Those three I consider the best of the Dwarf Beans.

Of Runners I find Scarlet Champion a long way ahead of the old Scarlet, especially when the plants are given stakes, as its pods are truly grand, we having had them 7 inches long, not a few picked pods here and there on the rows, but by the bushel. I have no fault, however, to find with the old Scarlet, as it crops well and gives useful pods, which fill with beans more quickly than Champion, which is a matter of consequence, especially in a dry season like the past one, and nothing taking so much from the energies of the plants as seed-formation we are pointed to a more speedy exhaustion. What of the Giants? I have only grown Giant White, an excellent cropping sort, with long fleshy pods, but I consider it tender, and if grown should have stakes. Girtford Giant I have not grown, but if it only gives pods 7 inches long in what is it superior to Champion?—UTILITARIAN.

STEPHANOTIS AND GARDENIAS.

I FAIL to see how Mr. Muir arrives at the conclusion that I regard these as the only pretty and good flowers, inasmuch as I mention at page 324 some twelve other choice genera, exclusive of the two above-named, of our best plants for cutting. It would not assist if Mr. Muir had known hundreds instead of scores of growers with bitter complaints as to the increase of mealy bug in mixed collections after the introduction

of Gardenias, for I feel sure that many hundreds of gardeners, and nursery-men too, are compelled to grow both in a collection of other plants, the places, either trade or private, where special houses are devoted to them, being in the minority. Those healthy Gardenias at Chilwell are associated among a great variety of stove plants, which include, if memory serves me right, choice Palms in variety, *Eucharis Sanderiana*, *Jasminum gracilimum*, various stove bulbous plants, *Allamandas*, *Orchids* in variety, and many more. Mr. Pearson points to the fact, as also do several correspondents, myself included, that these plants may be grown minus that dreaded pest, and cases innumerable have been brought to light where once they abounded, but now unknown. Moreover, Mr. Pearson says his Gardenias "have not been washed for years." I saw these plants a little over twelve months ago, and most creditable they were, and if Mr. Muir would only persevere, he, too, like Mr. Pearson, would be free of these plant parasites. "Bitter complaints" will never get mealy bug out of plant stoves, but give them a dose or two of petroleum, examine them once a week, and await the result. In the list of substitutes Mr. Muir names *Bouvardias*, which will harbour bug as badly as most plants, but it must be kept under. Mr. Muir protests against wire for *Stephanotis*, but can he utilise the long delicate tubes of *Bouvardia Humboldtii* corymbifera without these or similar aids? if so, I shall be grateful if he will inform me. I have grown *Bouvardias* by thousands, and have cut and wired the produce of hundreds of plants. Either for wedding or ordinary bouquets, wreath or buttonhole work, artificial stems of some kind must be used with many *Bouvardias*, and other plants too, unless you are prepared to sacrifice a quantity of lateral blossoms.—E. JENKINS.

OUTDOOR PEACHES FROM JULY TO NOVEMBER.

To many readers the above heading will doubtless appear strange, but our experience of the past three years quite justifies the phrase, and as the planting season is now at hand a few remarks on the subject may possibly be of interest to those of your readers who has not yet dispatched their orders for trees. It may be as well to state that this note is applicable to the southern counties only, and, further, we do not wish to imply that a continuous supply of fruit can be had except where a large collection of varieties and a good number of trees are grown, these being on the three different aspects of south, east, and west. Even under these conditions there may occasionally be a break of a few days. In our own case, however, we have this season only experienced two—viz., the second week in August, and the third week in October.

Taking the varieties in the order of ripening, we have first Alexander, a really high-class early variety, and of which we gathered our first ripe fruit this year on July 20th; for flavour, colour, and size it is superior to any other early sort with which I am acquainted, and in my opinion is destined to become very popular when better known. It is said to have been raised and sent to this country by our American cousins; it would be interesting to learn its parentage.

Early Beatrice is a few days later than the preceding, still it is a very useful Peach and well worth growing; its chief defect is its being small, and when fully ripe very thin-skinned and easily bruised—not very great faults certainly.

Early Louise is very similar to the last named, but by many considered to be the better of the two; fruit medium size, highly coloured, and of good flavour.

Early Rivers, fair-sized fruit, pale straw colour, but in my opinion not worth growing owing to its cracking or splitting propensity.

Early York, until recent years first favourite amongst early Peaches, ripens in August, and too well known to need any lengthened comment. Suffice it to say that no collection is complete without it. This brings us to the end of our list of the early-fruited varieties, and I would certainly advise the planting of at least one tree of each on an east or west wall to prolong their duration of fruiting.

Royal George still holds its own, and is a very reliable free-fruited mid-season Peach largely grown in most districts; with us, however, it is perhaps more susceptible to mildew than any other variety.

George IV. is nearly lost to cultivation, but it is difficult to say why, as it possesses real merit, being strong-constituted, a free bearer, of good flavour and colour, and large size. The oldest Peach tree in our collection is of this variety, and our wall man John, who has been here many years, says that he has never known it fail to give a good crop.

Dr. Hogg, a large handsome Peach, is well worth growing if only for appearance, ripens towards the end of August or beginning of September, and of very fair flavour.

Noblesse is an excellent high-class variety that should find a place in all collections; it has also the additional merit of being very hardy and a good grower, but does not at all times set freely.

Barrington may invariably be depended upon to give a good crop; fruit large and quality first-rate; all points considered it may be regarded as one of the best of our mid-season Peaches.

Sea Eagle.—Within the past few years this variety has been brought prominently before fruit-growers through the horticultural press, and in my opinion deservedly so; indeed, if I were compelled to grow one late variety only it would be Sea Eagle. The fruit grows to a good size, averaging about 10 ozs. when not overcropped, highly coloured on the sunny side, of excellent flavour, strong constitution, and free bearer; a character honestly given, and which ought to satisfy the most fastidious of specialists. Duration of ripe fruit this season from September 18th to October 12th.

Walburton Admirable is in all respects a high-class Peach, being of large size, highly coloured, and good flavour. In some localities it is

rather a shy bearer: with us, however, it is very free, and regarded as second only to Sea Eagle.

Late Admirable.—A very useful variety, of good size and fair flavour, but scarcely worth growing beside those previously named. The same remark is applicable to Prince and Princess of Wales and Lord Palmerston; still they are excellent for kitchen purposes.

Salvey.—This is the latest Peach of all, coming into use at the end of October and beginning of November. The fruit when well grown has certainly a grand and imposing appearance, and if ripened under favourable conditions the flavour is excellent; it cannot, however, at all times be depended upon.—H. J. H.

ANNUAL MEETING OF THE YORKSHIRE ASSOCIATION OF HORTICULTURISTS.

ADDRESS BY THE REV F. D. HORNER.

[At the last annual meeting of the above Association, held at the rooms of the Paxton Society, Wakefield, the Rev. F. D. Horner delivered an interesting address upon the general objects of the Association, and this was supplemented by a lecture on the Auricula. We have been favoured with the MSS. of both these, and as they are of far more than local interest we present them to our readers.]

(Continued from page 382.)

If I may without tediousness pass on now to speak of the Auricula from a florist's point of view, I cannot better lay the subject before you in the abstract than by reproducing the words of a brother florist, Rev. F. Tymons, who says, "The points of a good flower are not arbitrary, as the uninitiated sometimes say, but really appeal to rules of beauty recognised and allowed by all who have made a study of the flower. Thus, as in other matters of beauty and taste, the verdict of those most skilled in the subject is that which is entitled to weight. Rigid attendance to these points is of proportionate importance in any flower which is largely the creation of skill stretching forward to some ideal standard."

"Capability of modification under culture so as to draw nearer and nearer to that standard, is one of the prime distinctions of florists' flowers. Among these, none probably are more our creation than the Auricula. Hence the importance of a thorough knowledge of what a flower ought to be." Nature suggests, and leaves us to work out with her those suggestions. Hence when we find the Picotee gifted with the property of a beautiful wire edge of some soft tint upon its white petal, we at once see that that wire edge must be more perfect upon a smooth-edged petal than a jagged or fimbriated one. So of the Pink in the smooth petal that most sets off its lacing. Where the Auricula displays rings of colour on its flower disc in many velvet and enamelled textures, we see at once the full circular shape is better than the wingy windmill style of petal that cuts the zones in gaps and lets daylight spaces into the beautiful design.

In fact, whatever a man may be as an uninitiated and outside objector, he becomes what florists are if it is vouchsafed to him afterwards to become a florist.

Florist Auriculas are divided first into two broadly distinguished groups—the edged flowers and the Alpines. The main lines of separation here are the unmealed centres and shaded petals of the Alpine classes. In the edged Auricula the centres are all densely mealed, and each colour is of one uniform unshaded kind. The highest type in the Alpine (this term is technical here, and not to be confounded with the botanical use of the word alpine) is the golden centre and heavily shaded petal; the paler the centre and the less the shading the weaker is the flower in its properties. This section is the hardest and most prolific of all Auriculas, and those that are generally grown in garden borders are Alpines of more or less watery blood and inferior strain.

The other group is the Auricula Royal, containing all the edged classes which constitute the highest and most wonderful development of the flower. In these all the play of the flower in variety of colouring lies in the two outer rings or zones known as the edge and body colour; the two inner, the circle of the mealy paste, and the tube are constant in all. The paste ought always to be a dense smooth circle of white meal, and the tube a golden centre, prettily fringed with the gold-dusted anthers at its mouth. The stigma in Auriculas of each group and in every class must be below the anthers and almost sessile on the ovary, or it is the pin eye, which is a disqualification, as giving the tube and the whole flower a hard stony vacant look, for the mossy anthers in this case are always sunk to the bottom of the tube. The green edges are accounted the highest rank of all. They are the most difficult to obtain at all, and are rarely, even yet, obtained good. They have the richest play of contrast in their colours. An edge of pure emerald green outside a zone of black velvet, and that again succeeded by a circle of snowy meal with enamelled throat or tube of gold, is a flower of wondrous and rare type of beauty truly.

The green edges are the only class in which a mealy habit of foliage never occurs. The contrast of their zones of emerald black and white in a setting of silver leaves would be very beautiful, but Nature denies this combination, though often granting the converse in white edges with green foliage. The deposit of what we call meal upon the flower and its leaves is curious, and we may often have wondered what its nature is. The latest light I know of on that point is the interesting result of some carefully conducted chemical experiments that have been made by a brother florist, Mr. Worsley of Clifton. He has found this meal to be a vegetable oily or waxy substance, and is working this matter out further. There certainly appears on the thick green foliage of some varieties an oily deposit, and it is pungent to the lips, as you will find if you blow the water out that may have got into the heart of the plant, while a thin film of oily matter is sometimes seen on a wet leaf not exposed to washing by rain. It may be an abundant secretion of this matter that coagulates upon leaves of some varieties and gives them the snowy habit which we called mealed. The matter, however, is interesting, and I thought I would name it. The next class to green edges are the greys, in which a sprinkling of meal, like hoar frost upon grass, lies delicately over a green foundation without hiding it further than to give a pearly semi-transparent effect, as of a silver dew crystallised upon it.

The class following are the white edges. It is very hard to say which is best where all are beautiful; but the white edges are the fairest to see. The white edge is the Auricula in her bridal dress. The whole face of the flower, except the one feature of the velvety body colour, is veiled in a fall of softest snowiest meal. Good true whites and good true green edges have been very few so far.

Then follows that beautiful consort of the edged classes, the self. Really it is itself an edge, and used to be called self-edged, the space allotted to two zones of colour in other classes being here occupied by one in a double breadth, the colour being one rich tint from the edge of the paste to the rim of the petal. The self, with its mealed paste and colour of one decided hue, is a very different flower from the Alpine with its unmealed centre and heavily shaded colour, and not the least approach of the one to the distinct properties of the other can be tolerated. If an Auricula has one unshaded colour it should have white paste and be a self. If it has a well-shaded colour it should possess the golden unmealed centre and be an Alpine. Those are the differences that form the class distinctions in the florist Auricula, and in all the colours should remain true and fast, not fading into sere or weaker shades. A good flower dies well. One word—as I have said in other remarks on our flower—one word may suffice to express the share which the flowers of all the classes should apportion to their zones, and that single word is balance. The flower should be well balanced.

In form, circular and flat; in substance, stout and lasting; in size, moderate, certainly not big, but moderate. In the currency of the Auricula we want no crown pieces and get no threepenny bits; a pip the size of a shilling is small enough, and one like a florin is quite large enough. As a rule a flower suffers more by over size than under. It is soon coarse and rough in the grain. The Auricula is a jewel. It is one of the oldest of our exhibition florist flowers, for there were exhibitions of Auriculas in Lancashire more than 150 years ago. It was an English resident as far back as 1570, brought into the east and north-west of England by those Flemish weavers who brought to this country the craft of handloom weaving of woollens and with them these favourite home flowers. In 1725 we have proof that the culture of the Auricula was established in Lancashire. For a period of some fifty years then no record of it exists, but in 1830 the flower was grown abundantly in Lancashire districts; but independently of that, fifty years back from now almost every district in Yorkshire, Staffordshire, and Cheshire had its circle of Auricula growers. So too in Scotland and in the south of England. There were shows and societies in the home counties, and many growers in places which are now simply brick-and-mortar London.

(To be continued.)

FORCING SEAKALE.

As the time has now arrived when choice vegetables are comparatively scarce in the outside garden, and gardeners not having proper accommodation for forcing will be studying how they can best supply the requirements of the cook in the shape of delicate vegetables to fill the vacancies that have occurred through the loss of the crops of Peas, Beans, &c. Where a Mushroom house is in existence little difficulty will be experienced in obtaining a supply of Seakale from November onwards. To secure this no time should be lost in taking up a number of roots (according to the accommodation and requirements of the family) and place them

as thickly as possible in pots, and fill in with soil from underneath the potting bench or other material that might be at hand, then giving a good soaking of water, allowing them to remain outside for a few days. In the meantime have a slight hotbed made in Mushroom house, and as soon as a gentle warmth is perceptible plunge the pots in it; at the same time place pots of the same size over these, covering the whole with leaves and litter. Great care must be taken, and the trial sticks frequently tested, to see that there is not too much heat, as hard forcing thus early in the season would possibly spoil the crop. We have kept up a supply in this way until February. At this time we placed pots over crowns on permanent beds outside, which we covered with leaves and litter in the usual way, and in the course of a fortnight a second batch was treated in a similar manner. There was little trouble attached to the third batch, as the material from the first was ready to be removed, and with the addition of a little litter did service for forcing the third batch, then the pots were taken from the first and the crowns covered with litter, and placed over the last batch, and sufficient leaves put on to keep them in darkness, which was all that was necessary to keep up the supply as long as it was possible to do so.

My plan is to grow sufficient plants each year for forcing in pots to the above-mentioned time, as I think there is a great saving of labour in carting material, &c., that would be required if the whole was forced in established beds. When the crowns are taken up in autumn we carefully preserve the roots of these, covering them with soil, and as soon as convenient those about the size of one's figure are cut into lengths of about 6 inches, the top part is cut level, and the lower end in a slanting direction. In doing this it is more readily understood by the planter, as where this has not been attended to I have frequently noticed the bottom end placed uppermost. After the sets are prepared they should be covered with soil, and there remain until March, when they should be planted in good soil at about 1 foot apart in the rows, and 2 feet from row to row. These sets will send out several shoots, which must be reduced to one, which will form a good crown the following autumn. Established beds should undergo the same process as to disbudding, &c., but the beds should receive a liberal dressing of manure, which should be slightly forked into the beds. By adopting this method I have found no difficulty in keeping a full supply of this vegetable from the middle of November, and as long as it was possible to have it the following year.—ROBT. D. LONG.

AMONGST THE CHRYSANTHEMUMS.

THE Chrysanthemum season has commenced. The first three shows have been held, and intending exhibitors are busily preparing to test in competition their skill as growers of the varied and beautiful flowers now so widely popular. Those have entered for the more important classes at large shows are anxiously watching the blooms, and perhaps in some cases selecting those that are likely to be required, allowing a sufficient number over to provide for accidents. This selection is an important task, and good chances of success have been lost by deferring it until the last moment, when a hurried search for blooms necessary to complete a stand of twenty-four varieties often results in two or three small or imperfect specimens being included, which destroy the uniformity of the collection, and it has to take a second or third-rate position. Even where several hundreds of plants are grown the difficulty is frequently great to procure sufficient first-rate blooms for the large classes, and where the grower is intending to compete at several shows on different dates still more care is required in the selection. At present it seems that the incurved varieties are rather late, and at the earlier shows the Japanese will probably prove the stronger (this certainly is the case in several collections), and attempts at forcing may prove disastrous. Experienced growers are well aware of this, but beginners require caution, for we have seen some promising blooms spoiled by too great a hurry to have them out. The more gradually and naturally the blooms develop in a cool but not a damp stagnant atmosphere the more satisfactory they will prove when placed upon the exhibition boards. There is another point that is also occasionally lost sight of—namely, that good, solid, clean, well-finished blooms of medium size will rank higher than larger, rough, coarse samples. Substance is an important quality in a Chrysanthemum bloom, but is not synonymous with size as some seem to suppose.

Competition is expected to be brisk in the principal shows, but the chief interest in the metropolitan district will no doubt centre in the Kingston and Aquarium Exhibitions. At the former the challenge vase will bring renowned growers together, and it is said that this year a new competitor will contest the honours with them. There is a very general desire that the competition may be extended to another year, though the winner will unquestionably deserve the honour he gains, for the contest will be a close one. At the Aquarium the large money prizes will induce some good growers to enter, while at Richmond and the Crystal Palace the prizes are also sufficiently substantial to insure satisfactory exhibitions.

The following jottings will indicate the general condition of the Chrysanthemums around London, the collections named being some of the principal and most representative. There are many new varieties, of which some are mentioned in the following notes, but others will be reserved to another occasion, when a better judgment can be formed respecting their merit.

FINSBURY PARK.

An excellent show of 1500 plants has been again provided at the pretty North London park under Mr. Cochrane's superintendence, and is attracting large numbers of visitors, especially on Sundays, when several thousands pass through the house devoted to the Exhibition. The idea of

commencing a display of this kind was an excellent one, and it has been so well carried into execution that the Finsbury Park collection now ranks as the best of similar public shows. This is partly due to the judicious liberality of the Metropolitan Board of Works, and to the fact that Mr. Cochrane, with the aid of his experienced practical foreman, Mr. Mardin, has produced plants and blooms in first-rate condition, thus giving something more than mere popular interest to the display. This season the plants are arranged in two banks sloping upwards from the central path, and as much care has been exercised in arranging the various colours, the general effect, viewed from either end, is very beautiful. At present the Japanese predominate, as the incurved are not yet all out; but there are fine blooms of some of the varieties, such as St. Patrick, which is rarely seen so good, Lord Derby, Mr. Bunn, Prince of Wales, Lord Alcester, Alfred Salter, Emily Dale, and Mrs. G. Rundle. Of the better known Japanese some of the best are Lady Salborne, which keeps very true; James Salter; Elaine, wonderfully good; Margot, large and of fine substance; M. Henri Jacotot, which is in grand form, as it is indeed in most collections this year; Comte de Germiny, Chang, Etoile Toulousienne, M. Astorg, and Tendresse. There is a suitable proportion of reflexed varieties, the bright yellow Chevalier Domage being especially fine, as also is King of the Crimson, several blooms of which are 6 inches in diameter, of good substance and rich colour. Ten in front of each bank is a row of dwarf Pompons, chiefly of the Rosinante and Sœur Melanie forms, the latter being loaded with its pure white flowers.

Recent and new Japanese are well represented by some of the best forms, showing their characters well. Frizou is a striking flower of good substance, with bright yellow fluted and slightly recurved florets. Souvenir du Caire, rich maroon with a yellowish reverse, is good. Beauté des Jardins, of a distinct purplish crimson tint, very free, is likely to prove a useful variety. The blush Brise du Matin, and the rosy crimson Madame de Sevin, are both substantial blooms that have attained a good size. Joseph Mahood is a floriferous yellow or bronze variety. The rose and white Mons. Tarin, the red and bronze thread-like Madame Eugénie Pourquie, and purplish and silver Souvenir de la Reine Marie, are all notable varieties. The plants are in excellent condition, well clothed with healthy foliage, and there will be a good display of blooms for at least three weeks.

A CHRYSANTHEMUM NURSERY.

Mr. N. Davis, Lilford Road, Camberwell, has provided his usual exhibition in his nursery, and the large show house which he had specially erected for Chrysanthemums is now gay with an extensive collection of new and old varieties. The house is a span-roof structure 65 feet long by 32 feet wide, and contains 1900 plants arranged in ten groups, the greater part in the centre. The varieties are mostly associated in accordance with their colours; thus the orange, yellow, bronze, and reds occupy the centre, the end groups comprising the white, crimson, and pink varieties. This is a pleasing variation of the usual method of arrangement, and produces an excellent effect. The plants are thoroughly well grown, are clothed with healthy foliage, and bear numerous, handsome, substantial blooms, a large proportion of which are fully up to exhibition standard. The collection is a remarkable one, for not only are all the good recent and old varieties included, but the continental varieties for the present year have been obtained, and are being fairly tried for comparison with those of proved merit. Those trials and comparisons are of much importance, and for his own credit Mr. Davis is particularly careful not to recommend any but what he proves satisfactory and distinct. Bestowing new names upon older varieties is becoming too common a practice, and those who grow the new French varieties cannot be too careful in ascertaining whether they are really distinct before placing them in commerce. We have an instance of the care needed in the case of La Purété certificated last year at the Crystal Palace, which has now proved to be Mlle. Lacroix. We cannot now refer at length to all the new varieties at the Lilford Nurseries, but a few of the most prominent may be mentioned. Amongst the Japanese Val d'Andorre is a thoroughly good variety, the blooms of great substance streaked with bright red on a yellowish ground. Lakmé, bronze-yellow fluted florets, pretty, distinct, and of medium size. Jupiter, likely to prove a handsome variety of the Henri Jacotot build, but of a very bright lively red hue. Mlle. Crouzette, not one of this year's novelties, but better than we have hitherto seen it, the florets quilled half their length, then expanding broad and flat, of a clear pale pink, becoming nearly white. L'Aube Nationale is a pleasing variety in the way of Triomphe de la Rue des Chatelets, with fluted florets, silver and red. L'Adorable is in the style of Val d'Andorre, the florets fluted, rich yellow with a narrow reddish margin. Dr. Barrie, is a curious variety with large blooms, some of the florets quilled and golden, others flat and bright crimson. This is very remarkable, and is already a favourite with many who have seen it. Mons. N. Davis, of the J. Delaux type, neat, compact, bright maroon, and with a good centre, is a promising variety; and M. Harman Payne, described as a sport from Marguerite Marrouch, appears promising from late buds, the early ones being rather poor in colour.

Older varieties, including the last two or three years' novelties, are very numerous; still, amongst the Japanese Madame de Sevin is in capital condition, the smaller bright yellow L'Or du Rhin being a useful decorative variety, with which may also be associated the taller-growing but free bronzy yellow Joseph Mahood. Beauté des Jardins is a useful decorative variety, the colour a fine bright rosy crimson or purple, the blooms of medium size, but freely produced. Agrements de la Nature and Alexandre Dufour are good for the same purpose. Notable also are Mons. Tarin, M. Juan Cruz d'Equileor, Frizou, L. Negre, Garnet, J. Delaux, Triomphe du Nord, Madame Audiguer, Mrs. Townsend, Flambeau, Source Japonaise. It

might be added that Mary Salter, as grown by Mr. Davis, is much like Fair Maid of Guernsey.

The incurved are later and are not yet at their best, though there are good blooms of Prince of Wales, Mr. Bunn, Empress of India, Lord Wolseley, Lady Hardinge, and Lord Alcester. The early flowerers, Madam Desgranges and its golden sport G. Wermig, are still beautiful, the latter having been in flower for over three months.

MORDEN HALL, MERTON.

For several years Mr. Gibson, the gardener at Morden Park, has grown Chrysanthemums with remarkable success, and this season he does not appear likely to lose the credit he has gained. He has 400 plants, each bearing three or four blooms of exhibition size and substance, forming one of the most even and meritorious collections that we have seen. The blooms are much earlier than the majority around London, and this may prove a source of weakness in some of the severe contests they will have to endure, but at present there is little to fear on that score. Both Japanese and incurved are of excellent substance, large but clean, and free from all objectionable coarseness. All the best new and old varieties are grown. Here again we saw Madame de Sevin in good condition, and Mr. Gibson recommends it strongly as a useful variety that ought to be included in every collection where Chrysanthemums are grown for exhibition. Mr. J. Laing is also good, of a bright reddish hue from late buds, and is in that state much superior to the early blossoms. The beautiful Japanese Anemone Sœur Dorothee Souille continues gaining favour deservedly, and at Morden Park is very fine; its companion, Fabian de Mediana is, however, much later this season, and up to the present we have not seen a good representative bloom of it. Reflexed varieties are well grown, the bright yellow Chevalier Damage being uncommonly good, while the Violet-scented Progne, the deep-coloured King of the Crimson, and the Christines are all notable in this section. The other varieties in the respective groups cannot be enumerated, for so many are good. The plants are arranged in vineries and constitute a handsome exhibition, which is open to all visitors.

COMBE LEIGH, KINGSTON.

About 250 plants are grown by Mr. C. Orchard, not for yielding exhibition blooms but for decorative purposes, and his success in this respect and in grouping is well known. The charming and useful dwarf plants are as usual excellent this season, and bearing fine flowers, a good proportion of which are quite fit for the exhibition board. One variety with which Mr. Orchard is particularly pleased is the Japanese M. Henri Jacotot, which in all stages, either as dwarf, medium, or tall plants, is free and of first-rate quality. Some dwarf specimens, 2 or 3 feet high, have six grand blooms each, of great substance, and intensely rich crimson maroon with golden tips. La Purété and Mlle. Lacroix are here again proved to be identical, and the former name must be discarded; the variety is, however, an excellent one, and some standards have twelve to sixteen of its pure white blooms, extremely useful for arranging in groups. Cullingfordi is in splendid condition, the blooms 5 inches in diameter, very solid, and unrivalled in the intensity of its rich crimson colour. Val d'Andorre is again noteworthy, as also are M. Astorg, Beauté des Jardins, Yellow Dragon, Joseph Mahood, Gloria Solis, Agréments de la Nature, Mrs. Mahood, M. Tarin, and Elaine. A pretty old variety, but seldom seen, is Bras Rouge, not large enough for cutting for exhibition, but fine as plants for groups, the colour something like J. Delaux, but brighter and with a golden reverse. As elsewhere the incurved are not fully out; there are some fine blooms promising, and when Mr. Orchard has the plants arranged in the pretty conservatory at Combe Leigh they will undoubtedly form a group that could scarcely be surpassed.

SWANLEY.

As is well known Chrysanthemums form a special department of the "Home of Flowers," and are in charge of an expert who devotes his whole thought and time to their propagation and culture. Every section is represented, all established varieties grown, and new ones added from American, French, Chinese, Japanese, and English raisers. The collection embraces about 900 named varieties, represented in about 5000 plants. There are arranged in five new span-roofed structures, a walk passing down the centre, and the soil excavated on each side, so that the pots are 2 feet or so below the floor level, and the blooms are consequently brought literally "under the eyes" of spectators. They are from ten days to a fortnight later this year than usual, in consequence of the prevalence of north and easterly winds. Only a few of the earlier varieties are flowering, but in the course of ten days and onwards till Christmas there cannot fail to be an imposing display. Amongst the few in flower a grand bloom of Jeanne d'Arc, beautifully coloured, attracts notice, and well confirms what has been said as to the great value of the variety. A new variety named Ensign, received as a Japanese, has proved to be a true incurved, but whether totally distinct from some others of its colour, pinkish lilac, can only be proved by comparison. Since some of the best judges in England have been deceived in awarding a certificate to an isolated variety, the test of actual comparison of so-called new with existing forms becomes the greater for avoiding the mistakes in future. Mlle. Lacroix and La Purété, the last certificated last year, are identical at Swanley, if not everywhere else, and persons who possess the latter will do well to give it its right name, Mlle. Lacroix; it is a charming white Japanese variety well worth growing. L'Triomphante (De Reydelet) is effective at Swanley; it is a large Japanese, with broad, flat, drooping pale peach-coloured florets something like Brise du Matin. Henri Jacotot is free and fine, crimson, tipped with gold, and will be extensively grown

for conservatory decoration and for the front rows of exhibition stands of Japanese blooms. Sœur Dorothee Souille is one of the Anemone Japanese that will find its way into all collections. The pretty old reflexed variety Phidias is restored, as it deserves, from its long obscurity, and King of Crimson, with Emperor of China, are very fine in the same section. Several dwarf floriferous forms of Japanese will be valuable for small greenhouses and conservatories generally, also for affording cut flowers. Firmament, crimson, tipped gold, is extremely free; so are Isidore Ferral, pale pink, and A. Dufour, rich magenta; but the darkest and richest of all is Black Douglas, purplish plum colour, but less floriferous than the others. The bright yellow early-flowering Pompon, Fiberta, is fading, but there are few more worthy of culture for late summer decoration.

The yellowish Pomponium (certificated) cannot be referred to approvingly, as the plant is the reverse of compact, however dissimilar the flowers may be from others. Something more than distinctness is needed now-a-days, and the feeling is growing that enthusiasts are somewhat too readily disposed to grant certificates for new varieties before their characters have been fully proved. Among the single varieties at Swanley, Miss Mary Anderson, silvery peach, is one of the best yet raised; and Rev. A. H. Glenny, rich chestnut, is in full beauty. Those are only a few noted amongst the "early bloomers," the great majority of the varieties only just showing the colour of the florets, but they will produce a fine effect by-and-by.

ROYAL NURSERIES, SLOUGH.

For years "Turner's Chrysanthemums" have long been famed for excellence of culture and the great number of plants represented in the annual displays. This year they are, if possible, finer than ever, and in a short time will produce a magnificent effect. Three or four large houses are filled with some 4000 plants, and there are probably 3000 more under a framework and protected with mats. These are varieties of the Rundle type, mainly grown to meet the great demand for early cut blooms. It would astonish those persons who think Chrysanthemums cannot be well grown except in 9 and 10-inch pots to see the vigour of the stems, clothed to the base with luxuriant foliage, on plants in 7-inch pots. As in other places, the blooms are late, and the majority will not be fully developed till the middle of this month. Flowering now and very fine are Lady Selborne, which is appreciated because of its character being so unlike that of Madame Desgrange, which it succeeds, and on that account is preferred to Elaine; Cassandra, a white rose-shaded incurved variety, very attractive; Empress of India and the golden form, also Lord Alcester, large and fine; Jeanne d'Arc, excellent; John Salter, Mr. Bunn, Sir Stafford Cary, Virgin Queen, and some other early incurved well represented. In addition to Lady Selborne the following Japanese forms are highly effective:—Alum plenum, Margot, A. Dufour, Chinaman, F. A. Davis (J. Delaux), George Gordon (L'Africaine), La Purété (Mlle. Lacroix), Flamme de Punch, Henri Jacotot, Flambeau, Golden Fair Maid of Guernsey, Source d'Or, Mons. Franchenau, Madame C. Audiguier, and Hiver Fleuri. These are a mere fringe of the collection, but they indicate the character of the coming display, which will undoubtedly rank amongst the greatest and best in the country.

ST. JOHN'S NURSERY, PUTNEY.

Some thousands of Chrysanthemums are grown by Mr. G. Stevens, and this year he has surpassed all his previous efforts in the production of fine blooms. The Japanese are of good substance and bright in colour, but the incurved are some of the best we have seen, being earlier than the majority, of capital size, clean, and even. He also has a sufficient number of dwarf plants this year to render his groups more effective and better finished, as was seen in the case of that at Kensington recently, when he secured the first prize. They are well clothed with foliage, an important point in producing a good group, and which unfortunately is not always fully recognised by exhibitors. A useful decorative Japanese variety, which is grown this season in large numbers at Putney, is a seedling named Mrs. Stevens; the blooms are yellow and bronze, the florets flat, and is extremely free and effective, in a dwarf state, with dwarf Elaines and Madame Desgrange; it is excellent for grouping or cutting. Another seedling Japanese, named Maiden's Blush, has large handsome blooms somewhat in the way of Hiver Fleuri, but greatly superior, quite distinct in the foliage, and of a soft blush tint. It is of strong habit, and appears promising. The single variety, White Perfection, certificated last year, is grown extensively, and the abundant graceful blooms are now expanding. Elaine is largely grown for yielding its blooms early and is then discarded, the later crop referred to last year not proving satisfactory.

INNER TEMPLE.

The exhibition in these gardens, which is opened to the public by the liberality of the Benchers, is now attracting large numbers of visitors. The general opinion is that Mr. Newton has this year provided an even better display than usual, the blooms promising more substance and being brighter in colour. About 800 plants are arranged in the house near the Thames Embankment, and include representatives of all the leading varieties together with some of the newer forms. Both Japanese and incurved are rather earlier than in most gardens, but there are still many more to come, and intending visitors will find a good display for fully another fortnight. The best of the Japanese are James Salter, Lady Selborne, Margot, Beauté des Jardins, Madame de Sevin, Mlle. Lacroix, J. Delaux, Val d'Andorre, Comte Germiny, and Curiosity. The incurved include Jeanne d'Arc in handsome form, Lord Derby, Jardin des Plantes, and Mr. Bunn as the best of the general collection. A Japanese variety

is shown under the name of Porcupine, which seems to be the same as Gloire Rayonnante, but how it obtained the former title does not appear, though Mr. Newton is not responsible for it. The florets are quilled up to the apex, but it cannot be commended as an attractive variety though it is certainly curious.

SWANMORE PARK.

Many persons will be anxious to know how the Swanmore plants are looking, and it may be said that, considering the "roasting summer" on the south coast this year, they are looking very well. If wood-ripening is an important element in the production of fine blooms there ought to be some good ones in this collection, for plants exposed to the full sun at an altitude of 450 feet above the sea cannot be otherwise than matured. Some persons say the wood can be over-ripened, that being a view held by some Liverpool growers, and we can only wait and see what the well-ripened Swanmore plants will produce. When inspected a few weeks ago it was too soon to form any correct estimate of the ultimate character of the blooms. Only a few early flowers, and these mostly Japanese, were approaching development, the first of the incurved, such as Jeanne d'Arc, Lord Wolseley, and Prince Alfred not being half-grown. They would, however, be quite early enough for the shows, if not too early; but as some early blooms, and these usually the finest, are nearly always lost by all the best exhibitors they meet on even terms as regards that contingency. Mr. Molyneux was amused by the remark of a correspondent as to his seeing a "red light." He does not over-estimate his own chances of winning, nor lightly regard the skill of his competitors. He will, as usual, do his best, as they will, for the coming contest. His plants—there may possibly be five or six hundred of them—vary in height from 3 to 10 or 12 feet, and the foliage was stout and the buds fat. He was anxiously watching the opening of Mdle. Lacroix and La Purété and shaking his head over them; he has perhaps found by this time they are both alike. A Japanese sport from Bouquet Fait was developing; it is quite distinct from the parent, having creamy rose drooping florets and was promising well, as was Mons. Planchenau, an improved Bouquet Fait, but much darker than the sport. Ferdinand Ferral, sent out as an incurved, was developing into a rosy pink large-flowered Japanese. M. Tarin, a large deep lilac Japanese, was favourably regarded, as was Val d'Andorre, Henri Jacotot, chestnut tipped with gold, was beautiful, but too early for showing. Laing's Anemone Japanese, Margaret Villageoise, gave promise of being a good variety, and Madame Clos and Belle Pauline were coming out well, as also was the distinct and beautiful Sœur Dorothee Souille. Mons. Mousillac and L'Or du Rhin were very rich and very much alike; and Pietro Diaz, sent out as a chestnut incurved, was being watched with some interest. The Swanmore Chrysanthemums are arranged in large light houses, in which the blooms ought to "colour up" well.

THE HIGHGATE NURSERIES.

Messrs. W. Cutbush & Son have arranged a large number of Chrysanthemums in the corridor and conservatory of their Highgate Nursery, and in the course of a week there will be a good display. The plants are late, as they appear to be generally, especially in the north of London, and even in the south it is feared that some of the earlier shows will be too soon for several growers. A careful selection of all the best varieties has been made in the Highgate Nurseries, and when the blooms are fully out visitors will have a good opportunity of judging the respective merits of the numerous claimants to popular favour, and will also be able to form a correct idea of the principal types of variation distinguishing the Chrysanthemums now cultivated. Amongst the earlier blooms there are already some handsome examples of Margot and a few other varieties of sterling merit.

VICTORIA AND PARADISE NURSERIES, UPPER HOLLOWAY.

Each season brings its special attractions at Mr. B. S. Williams' nursery, and in November one of the leading features are Chrysanthemums, which are arranged in the handsome conservatory facing the main road. They are placed in groups around the large Palms, Ferns, and other fine-foliage plants, and are grown more with a view to show their usefulness as decorative plants than to produce a few large blooms of exhibition size. It is as free-flowering plants that Chrysanthemums are valued in the majority of gardens, and yielding as they do a plentiful supply of variously coloured blooms at a time when flowers are not too abundant, it is not surprising that they are so highly appreciated. Mr. B. S. Williams' plants show these qualities admirably, many of them being loaded with medium-sized blooms exactly fitted for cutting to arrange in vases or baskets. The most floriferous varieties distinguished by bright or pure colours have been chosen for the purpose, and they have been arranged with much taste. Such specimens as these Mr. Williams will employ largely with suitable foliage plants in the floral decorations of the Guildhall on the occasion of the banquet next week.

MESSRS. J. VEITCH & SONS, CHELSEA.

As with many other collections the plants in this one will not be at their best for at least a week. The earliest plants are placed in the corridor at the Brompton Road end of the nursery, several other houses being devoted to the general stock of old and new varieties. Of the latter about fifty are on trial, including a number of Mr. Salter's, several of which appear very promising, though it is yet too early to form an accurate judgment of their characters and qualities. Some of the earliest Japanese, and now in condition, are the following—Source d'Or, a free useful variety, with fluted yellow florets; Beauté des Jardins, rich colour; William Robinson, large, free; Boule d'Argent, crimson, silver reverse; J. Delaux, rich dark colour, and of good size; Henri Jacotot,

extra good; Criterion, of fine substance; Brise du Matin, full, handsome; L'Ile des Plaisirs, rich orange bronze in tint; M. Mousillac, intensely deep crimson, fine bloom; Isidore Ferral, lilac rose, free and distinct; La Charmeuse, purplish crimson, fluted florets, notched at the points; Eclatante, bronze red; Madame de Sevin, excellent as we have noticed it elsewhere; M. Viviani Morel, short, broad, white florets, somewhat of the reflexed type; Etoile Fleuri, bronze and yellow, with curiously notched florets; Comet, bronze red, one of Mr. Salter's varieties, of medium size, and very free.

There are not many of the new varieties in perfection yet, but Mons. Freeman, which was certificated at the Aquarium recently, is better than we have seen elsewhere, must be termed an incurved Japanese of a lilac colour; Mdle. Melanie Fabre, of similar colour, is more like a reflexed bloom, but is rather pretty. Souvenir d'Haarlem has rose-coloured blooms with fluted florets, and is of good quality. M. Paul Fabre, very bright red, is likely to be a good variety, and several of Mr. Salter's varieties which have not been named are promising well. The incurved blooms are much later, as they are generally this season, but there will be some fine blooms if the substantial buds expand satisfactorily.

MR. W. BULL'S NURSERY, CHELSEA.

It has been the custom at this nursery for some years to obtain and test the new varieties annually distributed by the continental growers, and Mr. Bull confines his collection to the best of these, the general stock of old varieties not being made a speciality. Numbers of novelties have been procured this season, and though the majority are still expanding and will need several days to reach their full size, some show their characters fairly well. The Japanese are again the most prominent. Lakmé, which has been already certificated this season, is in capital form, and evidently deserves the honour it receives, as it is also free and likely to be useful for decorative purposes. M. Henri Jacotot is handsome, and the new Mons. Ghys, with rosy lilac blooms, is noteworthy. Other good varieties are M.M. Thibaut and Keteleer, intensely rich crimson-maroon with a golden reverse; L'Aube Matinale, large, free, and handsome; Mr. J. H. Laing, large, with broad florets of a bluish tint, yellow in the centre. Golden Gloire Rayonnante is an American variety, said to be from the well-known quilled variety; but it does not resemble that in the slightest, though of a pleasing yellow tint. Several good Pompons are flowering, amongst them being Belle Navarraise, white fringe, free and compact; Neatness well deserves its name, the florets being very closely packed, in symmetrical ball-like heads of a pale rosy colour; Surprise, pink and white is a charming little floriferous variety, the plants having been in flower for three months; Petit Mignon is also a beautiful little variety, the purple and white blooms being particularly charming; Exposition de Chalons is pretty and distinct, the blooms freely produced, crimson and white. Many others are advancing, and we may have occasion to refer to them a little later in the season.

MESSRS. J. LAING & CO., FOREST HILL.

Several houses are devoted to the extensive collection of Chrysanthemums in the celebrated Tuberous Begonia nursery, and the best varieties are represented by well-grown plants, a large proportion of which are bearing handsome blooms of exhibition quality. No doubt some of these will be seen at the leading exhibitions during the season, Messrs. Laing's groups of plants being especially noted. There are many new varieties, several of this year's importations promising to be valuable additions to the already long list, and the approved of last year's novelties fully maintain their characters.

GROS MAROC GRAPE.

I BEG to inform "A. O. W." (page 389) that this is, according to my experience of it, a first-rate late Grape, and as such I believe it is destined to be extensively grown in the future. I have no experience of it on its own roots; but during the past summer I have planted a house with Madresfield Court, Alnwick Seedling, Muscat Hamburg (at the warmest end of the house), and Gros Maroc, the latter both on its own roots (for comparison) and on the Black Hamburg stock, as my experience of this grand-looking Grape is confined to bunches secured from this union. It is highly appreciated here, not only on account of the size and shape of bunch and berry and density of bloom, but also on account of its excellent flavour, the result, no doubt, of its union with the Black Hamburg, as the flavour of Gros Maroc when grown on its own roots is, according to statements which have appeared in the Journal within the last twelve months, only third-rate. Messrs. Thomson & Sons have found room for Gros Maroc in their wonderful Grape-growing establishment at Clovenfords; and, judging by the samples which I saw there a short time ago and my own knowledge of the Grape, I expect ere long it will be grown extensively in the Tweed Vineyard, and to such a state of perfection as all Grapes there, not excepting the Duke, attain, as to place it beyond all doubt as one of the best and grandest-looking late Grapes in cultivation.

To those who have given the Gros Maroc a trial and condemn it on the score of indifferent flavour, I would say, Try it on either a Black Hamburg or Muscat of Alexandria stock, and the improvement in flavour consequent upon such union will be such as to place it equal to, if not before, that of any other late black Grape grown.

While on this subject I may state for the benefit of those of your readers who may not have had any experience of the "influence of stock upon scion," that wherever it is deemed necessary to extend the culture of any particular Grape by the process of grafting or inarching, the character of the variety on to which it is intended to place the scion and the probable consequences that such a union would lead to should be duly

considered before performing the operation—that is, let there be no hazard choosing of stock, but let the object in view be distinctly seen before pursuing it. There is no better stock for grafting or inarching (I prefer the latter mode of propagation) any variety of Grape on than the Black Hamburgh. I go further than this by expressing my firm belief that every variety of Grape in cultivation may be more or less improved by being grown on the Hamburgh stock. Next to this comes the Muscat of Alexandria. On the other hand, put either of these varieties (Hamburgh and Muscat) on a Gros Colman, Trebbiano, or Alicante stock, and the result of such a union will be a deterioration of flavour. There can be no doubt, I think, about Gros Maroc, Madresfield Court, and Alnwick Seedling doing satisfactorily together in the same house. As reference has been made to the Golden Queen Grape, I may be allowed to say that when grown and staged at the Edinburgh Show by Mr. Murray of Culzean Castle, Maybole, and Mr. Hammond, Brayton, it is a grand Grape, Mr. Murray's example of it being especially fine in size and form of bunch and berry and perfect finish. The same may be said of his specimen bunches of Alnwick Seedling and Muscat of Alexandria which were staged at the same excellent fruit show.—H. W. WARD.

PTERIS TREMULA.

THIS is one of the most useful and accommodating Ferns with which I am acquainted. It will stand in a room for months where no gas is used without any apparent harm, and does not easily lose its lower fronds provided it is regularly supplied with water. Like many of the Pterises it reproduces itself very freely from spores when standing over soil or near other plants in pots. These sporelings, when large enough to handle, should be placed into small 60-size pots, and as growth advances be transferred into 5-inch pots, which are large enough for ordinary purposes. It is surprising what a length of time it will last fresh without any repotting or adding fresh soil as top-dressings, and it would appear to be quite content with clear water only. It is not particular as to soil, but a mixture of loam, leaf mould, and sand would seem to suit its requirements exactly.—W. B. H.

It is with unfeigned regret that we have to announce the death of DR. HENRY GREAVES BULL of Hereford, after only a few days' illness, at the age of sixty-seven. Dr. Bull practised for many years as a physician in Hereford, and was a magistrate for the city and also the county, and there was no work of usefulness which was not aided by his untiring help. The Woolhope Club, which he did so much to make famous, will miss his masterful management, and the city of Hereford will lose one of its most devoted residents. Dr. Bull was a native of Northamptonshire, and resided in Hereford for many years till his death on the 31st ult. "THE HEREFORDSHIRE POMONA," the publication of which engaged so much of his attention for the last few years of his life, and which has been produced under his fostering care, was fortunately completed only a few weeks ago, and will ever remain a monument of his untiring energy and cultivated taste.

— ONE of the principal objects of the APOTHECARIES' BOTANIC GARDEN, CHELSEA, which has been established for 200 years, is the teaching of botany to medical students, and latterly also to young women and to ladies in training for governesses in public schools. During the present year the number of visitors, mostly students, has been 2784, of whom some 1200 were males and the remainder females. The Society gives a gold and also a silver medal in both classes of students to those who pass the most creditable examinations.

— THE FIRST ESTABLISHED HORTICULTURAL SOCIETY IN SCOTLAND.—At the recent Horticultural Show at Falkirk the Secretary, Mr. Haining, intimated that it was a hundred years since the first show of the kind was held in Falkirk, and was probably the first held in Scotland. Mr. Wm. Sword said that, according to old books connected with the Society at that time, there were neither trimming nor any artificial means allowed in bringing to competitions either vegetables, fruits, or flowers.

— THE PROPOSED PARKS AT HIGHGATE AND KILBURN.—The Common Council last week agreed to accept the offer of the Ecclesiastical Commissioners of land at Highgate and Kilburn for open spaces, and also that the Remembrancer should be instructed to give the notices

necessary for the introduction of a Bill in Parliament next session to enable the Ecclesiastical Commissioners to convey, and the Corporation to accept, the sites. It was further resolved that the interest of the residuary bequest of the late Mr. W. Ward (amounting to £20,000) should be applied towards the maintenance of the open spaces at Kilburn and Highgate.

— AT the meeting of the LINNEAN Society, which takes place to-night (Thursday) at Burlington House at 8 P.M., papers will be read on the following subjects:—1, "Flora of the Peruvian Andes, and its History and Origin," by John Bell. 2, "Monograph of Recent Brachiopoda," Part I, by the late Dr. Thomas Davidson.

— DR. BRAITHWAITE, 303, Clapham Road, S.W., has lately issued the ninth part of "THE BRITISH MOSS FLORA," which is in every respect fully equal to the preceding parts of this carefully executed work.

— AT Wakefield the usual weekly meeting in connection with the Paxton Society was held on the 24th ult., a very able and exceedingly interesting paper relative to the various modes of GROWING BRITISH FERNS was read by Mr. J. G. Newsham, a noted and successful amateur Fern-grower, at Sheffield, and it was followed by a capital discussion, in which several professional and amateur gardeners took part. Councillor Milnes presided, and Mr. T. Garnett filled the vice-chair. A very hearty vote of thanks was accorded to Mr. Newsham. It was generally admitted that the essay was one of the best ever read in connection with the Society, and the clear and interesting manner in which the essayist replied to a number of questions was much admired. A good collection of British Ferns was exhibited by Mr. Wassell, gardener to W. Vibart Dixon, Esq.

— WE are sure many of our friends will regret to hear of the DEATH OF MR. W. H. LASCELLES. He was well known and much respected throughout the horticultural trade. Those who have gone through his greenhouses with him will not soon forget his genial manners or his enthusiastic love of horticulture. Several years ago symptoms of declining health caused him to retire from his business at 121, Bunhill Row which is still being carried on by his successors.

— THE GLASGOW BOTANIC GARDEN does not appear to be in a very thriving condition. The Town Council recently held a meeting and have decided to allow the Society to continue in possession of the grounds until March 31st, 1887, any deficit then remaining to be supplied by the sale of plants or other property.

— A COMMITTEE, comprising the Rev. Canon Hole, Canon Swells, Canon Foster, Major Newton, Professor Blake, and H. Smith, Esq., has been formed to receive funds for a TESTIMONIAL TO MR. W. INGRAM OF THE BELVOIR CASTLE GARDENS, who has for thirty years contributed so greatly to an improvement of flower gardening.

— RELATIVE TO CURING DISEASED EUCHARISES, "W. W." writes:—"I had plants in a miserable state, the bulbs being infested with mites. The bulbs were taken from the soil and washed well with warm water; then before they had time to dry were dipped in soot, which, of course, made them black. They were next potted in very rough loam, sand, and wood ashes. It is important that the soil be very lumpy and the drainage as perfect as it can be made, so that the water passes from the pots nearly as quickly as it is poured in. I have noticed that when mites are present the soil has been too close and the drainage deficient. Our plants were nearly rootless and leafless. However, they flowered once the first year and twice the second. After the pots are full of roots I use soot water occasionally. The plants like this, and the mites do not; nor do the mites like wood ashes, while the plants enjoy them. The mites like decayed manure, and as Eucharises can be grown without it not a particle is mixed with the soil."

— TURNER MEMORIAL PRIZES.—We have received the following appeal in circular form, and readily publish it with the object of aiding the promoters in their commendable endeavour to appropriately perpetuate the memory of a great florist and excellent man:—"At a meeting held in the conservatory of the Royal Horticultural Society, South Kensington, August 11th, 1885, Shirley Hibberd, Esq., in the chair, a resolution moved by the Chairman and seconded by Dr. Masters, F.R.S., was unanimously adopted to the following effect—'This meeting is of opinion that the eminent services to floriculture of the late Mr. Charles Turner of Slough should be commemorated by means of special prizes for florists' flowers fruits &c. and hereby resolves to promote the raising of a fund

the interest of which shall be applied to carry into effect the said prizes, which shall be entitled Turner Memorial Prizes; the fund, and all its incomings and outgoings, to be administered by a body of trustees or governors to be hereafter appointed.' It was further resolved that H. M. Pollett, Esq., of Fernside, Bickley, Kent, be the Honorary Treasurer, and Mr. James Douglas, The Gardens, Great Gearies, Ilford Honorary Secretary. The importance of the present movement will be felt and understood by horticulturists of all grades and tastes, for in every department, and by men of all parties, the name of Charles Turner has been held in honour, both because of the high character and gentle manners of the man, and his earnest work as a practical and ever-advancing florist during a successful career of over fifty years. It is no part of the business now in hand to pronounce any eulogy, the object of this circular is to make a direct appeal to the horticultural public for the means of establishing the proposed Turner Fund. The promoters feel that the cause carries with it all the persuasions needful to success, and they urge upon all sympathisers with its objects the need of prompt attention in collecting subscriptions and forwarding them to the Hon. Treasurer without delay. Copies of this circular will be supplied wherever needed, and gardeners are requested to bring it under the notice of their employers, the object being to make a formal and impressive public record of 'appreciative and affectionate regard for the memory of the most distinguished horticulturist and florist of the nineteenth century. The subscription list will close at the end of December; any person wishing to contribute will kindly forward the amount to the Treasurer as soon as convenient. Head and under gardeners are earnestly solicited to subscribe."

— "F. J." writes:—"I have this year gathered three pods of ripe seed from a *CHIMONANTHUS FRAGRANS* tree on a wall, and shall be glad to know if it is unusual for seed to ripen in the midland counties."

— A BRILLIANT display of ORCHIDS IN NOVEMBER can scarcely be expected even in the largest collections, but Mr. W. Bull has in his Clesea Nursery one of the prettiest shows of these plants that we have ever seen at this time of year. In one house there are some scores of spikes of the handsome rich crimson *Lælia autumnalis atropurpurea*, the splendid colour of which affords a fine contrast with equally numerous blooms of *Oncidium tigrinum*, the lips very large and pure yellow. Then there is a magnificent bank of the old but handsome *Odontoglossum grande*, numerous plants of *O. Inseayi leopardinum*, and the sweet little *Trichosma suavis*, which fills the house with its Orange blossom perfume. In another house the valuable and beautiful *Aerides Lawrencei* is flowering, and is unquestionably the finest of its genus, the flowers of great size, of a waxlike creamy tint streaked with rosy crimson. A plant of the superb *Vanda Sanderiana* is also in excellent condition, bearing on three spikes no less than seventeen large grandly marked blooms, one of the spikes having ten blooms. Several other rare and beautiful Orchids are flowering and render the house very attractive.

— CONSIDERABLE attention has lately been drawn to the PRESERVATION OF NATIVE PLANTS; and at the cryptogamic meeting of the Essex Field Club on October 3rd, Professor R. Meldola (on behalf of the corresponding Societies' Committee of the British Association) directed the attention of the Club to the following resolution, which had been submitted to the Conference of delegates held in Aberdeen by Professor Hillhouse of the Mason College, Birmingham, and carried unanimously:—"We view with regret and indignation the more or less complete extirpation of many of our rarest and most interesting native plants. Recognising that this is a subject in which local societies of naturalists will take great interest and can exercise especial influence, we urge upon the delegates of corresponding societies the importance of extending to plants a little of that protection which is already accorded by legislature to animals and prehistoric monuments, and of steadily discouraging, and, where possible of preventing, any undue removal of such plants from their natural habitats, and we trust that they will bring these views under the notice of their respective societies."

— THE *American Grocer* says that a French savant claims to have discovered in COTTON-TREE SEED a nutritious matter, presenting some most remarkable features in its composition. An analysis of the seed of Cotton trees, of which several varieties are cultivated in Bolivia, shows that this is the richest of all known grains in nitrogenous substances. He is convinced that Cotton-tree seed will make a flour destined to take an important place as a food for man.

— GARDENING APPOINTMENT.—Mr. J. Wyke, who has until

recently been gardener to Mrs. Dunn, Henley Grove, Westbury-on-Trym, near Bristol, has taken charge of Mrs. Dunn's gardens at Eccleshall Castle, Eccleshall, Staffordshire.

— SHELTER TRENCHES FOR HORIZONTAL CORDON TREES.—Mr. T. Francis Rivers writes:—"A very cheap shelter for horizontal cordon trees may be made by planting them in trenches about 3 feet wide and 2 deep; the soil should be banked on each side of the trench. After settling the banks will be about 1 foot high, and will form the support for the protection against spring frosts. This may consist of straw hurdles or stakes laid across and covered with mats."

— MR. JOSEPH MALLENDER sends the following summary of METEOROLOGICAL OBSERVATIONS at Hodsock Priory, Worksop, Notts, for October, 1885:—Mean temperature of month, 45.2°; maximum on the 2nd, 57.9°; minimum on the 30th, 27.3°; maximum in sun on the 5th, 115.1°; minimum on the grass on the 30th, 20.2°; mean temperature of the air at 9 A.M., 45.1°; mean temperature of soil 1 foot deep, 47.6°. Warmest day, the 17th; coldest day, the 30th. Nights below 32° in shade, two; on grass, eleven. Total duration of sunshine in the month, sixty-eight hours, or 21 per cent of possible duration; we had ten sunless days. Total rainfall in month, 5.32 in.; maximum fall in twenty-four hours on the 23rd, 1.67 in. Rain fell on twenty-four days. Average velocity of wind, 11.4 miles per hour; exceeded 400 miles on four days, fell short of 100 on three days. Very wet, cold, and dull. In ten years we have only had two months with a larger rainfall—viz., December, 1876, and October, 1880. October, 1880, had also a lower mean temperature, and 1881 was nearly as cold; but in no previous years have we had such low day temperatures. Sunshine less than in any of the last four years.

— THE *Society of Arts Journal* records that the LARGEST VINE IN THE WORLD is one growing at Oys (Portugal), which has been in bearing since 1802. Its maximum yield was in 1864, in which year it produced a sufficient quantity of Grapes to make 750 litres (165 gals.) of wine; in 1874, 665 litres (146½ gals.); and in 1884, only 360 litres (79½ gals.). It covers an area of 494 square metres (5315 square feet), and the stem at the base measures 2 metres in circumference.

— EXTENSIVE TREE PLANTING IN MEXICO is now being undertaken by the Government, and contract has been made with Mr. Oscar A. Droege to plant 2,000,000 trees in the valley of Mexico within four years. The respective numbers are—80,000 Ash, 35,000 Willows, 120,000 Poplars, 60,000 Eucalyptus Trees, 60,000 *Troenos japonese*, 60,000 Mountain Cypress Cedars, 60,000 Acacias, and 120,000 of miscellaneous varieties. The trees are to be in plantations of from 50,000 to 100,000 each.

— AN American paper has apparently become very philosophical, and puts forward the following remarkable observation:—"A life devoted to the extermination of cockroaches is nobler spent than a life devoted to the gathering of Orchids." This will perhaps prove an alarming discovery to some similarly thoughtful readers, but we do not anticipate that many will be induced thereby to undertake the "nobler" employment.

WHITE GEM CELERY.

WHETHER the season has been too dry for the growth of Celery in gardens generally I do not know, but certain it is very little has been written concerning it this season so far as I have seen. The object of this note is to call attention to the above excellent variety, sent out, I believe, by Messrs. Sutton in the spring of last year. It is, as its name implies, a gem amongst white varieties, and should be grown in gardens, large and small alike, where early Celery is desirable. Seed was sown about the middle of March on a gentle hotbed, the plants brought on in the usual manner, and planted out at the end of May and beginning of June. The weather at the time being hot and dry, water was given morning and evening for a few days, until the plants were re-established in their new quarters. A mulching of short grass from the mowing machine was applied as planting was completed, and was replenished as often as necessary during the summer. A quantity of grass was also dug in the trenches to serve as manure. Water was given every ten days or fortnight, and then not the quantity usually considered necessary, as the mulching prevented excessive evaporation, and maintained a more equable moisture than would have been the case had no mulching been applied. The usual practice of earthing early and often was not adopted, nothing being done in that way until about a month before it was "fit to dig."

This might seem almost impossible to many readers, but not when I state that our trenches were deep and the plants so compact and dwarf that the upper leaves covered the trench, thereby producing semi-darkness to the lower part of the plants, causing them to blanch naturally. I

have never noticed this natural blanching so much as I have this year, and I attribute the cause to deep planting and excellent habit of the variety, other sorts growing by the side of the White Gem showing no tendency to blanch under the same conditions. Notwithstanding the unfavourable season, not one plant has "bolted" or failed in any way, and we commenced digging the best Celery the 1st of October, my employer says he has ever tasted, while in other gardens near the crop has been a partial failure, and in one instance a total one. Nothing could induce it to make any growth whatever. It would be interesting to know how the Celery crop has been in other gardens. It may be added no trace of Celery fly has been seen this year with us.—B., *Hants*.

"THINKER'S" NOTES.

USEFUL POTATOES.—Your critical correspondent "Thinker," I am afraid, does not always examine the articles to which he refers so closely as he might, otherwise he would see what was meant in some of them which he affects not to understand. While I have no objection whatever to his reference to my article, I "think," if he will allow me to make use of that word, it was apparent that my object in writing on page 331 was to learn something about the usefulness of the newer varieties of Potatoes and not to tell, what most persons know, which of the old ones are good. I have, however, not the slightest objection to name a "short list of varieties" that afford a supply of satisfactory produce all the year round. They are—1, the true old Ashleaf for sheltered positions; 2, Myatt's Prolific closely following in open quarters; 3, Sutton's Early Regent; 4, the Scotch, Regent; 5, Magnum Bonum. If your correspondent, or anyone else, can improve on this list, or can substitute any better varieties for any of those named, I shall be glad to know what they are and will try them, if I have not already done so and found them wanting. Sutton's Early Regent is not very old. It was recommended to me by a writer in the *Journal* and has proved a valuable acquisition. It follows closely after Myatt's, and is of first-rate quality in the rather light soil in which it is grown.—A COUNTRY GARDENER.

CANKER IN FRUIT TREES.—As our friend the "Thinker" is unearthened, which we are glad to see, and requires something to think about, may I suggest that he give us his opinion on the cause of canker in fruit trees? I have thought about it and written about it until I am tired, although I have a reply to "Entomologist," which I withhold for the present.—J. HIAM.

TRINITY COLLEGE BOTANIC GARDENS.—In common with all your readers and correspondents, whatever my engagements, I read the graphic notes of "Thinker," and I can reciprocate his kindly reference to me (page 375) by saying, "with pleasure" and profit. I can only regret "he as yet has no idea how extensive Trinity College Gardens are," but we must try and tempt him to remedy that and see Ireland, if not sooner, next year. As to "instalments" of my note—the one he refers to, which tried vainly to imitate him in brevity—it is, I think, the fourth of the kind sent to the *Journal* at different times, when I could run up to Dublin and enjoy the great treat of a walk round with Mr. Burbidge.—W. J. MURPHY, *Clonmel*.

SHOWING LATE GRAPES.—Notwithstanding my obscurity, as portrayed by "Thinker," I notice that a couple of paragraphs is sufficient at any time to make your correspondent pen about a dozen in reply, and it is an old saying and a true one, that a long answer to a short question is a sure sign of a bad case. "Thinker" does not, however, attempt to reply in this case, but resorts to his usual practice of throwing up dust to confuse spectators while he is effecting his retreat. In fox-hunting parlance I must, however, "keep his nose to the fence," and make him either jump or turn tail. According to his own showing, the whole or main object of showing Grapes, or anything else, is to bring gate money to the organisers of the show, whoever they may be, and that being so he tells us that late varieties of Grapes must be sacrificed to that end. Sporting matches of various kinds are usually promoted on similar grounds, and one does not see why fruit and flower shows should not go with these. I must deprive "Thinker" too of the shelter of secretaries of horticultural societies, because none of these has ever at least avowed such principles of action as those professed, more particularly as the question is one of showing fruits out of season. Like "Thinker," I claim that I am not a disappointed exhibitor. From a pecuniary point of view I can employ my time to better purpose than showing, but it would appear from what he "could tell," to use his own words, that he has had a good deal to do with disappointed exhibitors, who protested and threatened actions, &c. As to Mr. Knight and his contemporaries not knowing more about shows than did old Mother Hubbard, I believe it, if the gate-money plea gives a just conception of their view he takes of them; but though men may die principles last, and those principles applied to "Thinker's" objects and purposes of exhibitions show them in a very unfavourable light, that he seems now inclined to share even in these days.

I observe that he accuses me of "accusing a body of men of being engaged in a low calling," and I wish to state, in order to put myself right with your readers, that I have done nothing of the kind, nor had I any intention of doing so. At all events, I did not malign any body of men nor mean to do so, but simply accused "Thinker" of putting horticulture on a "low ground," and that I adhere to. Neither did I apprehend "Thinker's" remarks as "a narration of circumstances" as he puts it, but for what they profess to be—viz., his own "thoughts on current

topics," and I am surprised he should seek to repudiate them or put them forward as the thoughts of other people when they are criticised adversely.

Exhibitors are not responsible for the schedules of prizes of fruit shows, and "Thinker" does not seem to grasp the fact that the temptations put in the way of exhibitors, who must either conform to the schedule or stay at home, is one of the main evils complained of. As to what I have myself done in the way of exhibiting late Grapes, I am ready to give "Thinker" an answer on that point when he can show me what it has to do with his "thought" that "the whole question turns on the purpose for which the objects are staged" and that that "purpose is to bring gate money."—NON-BELIEVER.

AUTUMN APPLES.

DESSERT VARIETIES.—The first of these may be said to begin with Early Harvest, Early Margaret, and Juneating. The latter is the earliest of all Apples, and is closely followed by Early Margaret, which is our favourite early Apple. It bears freely in the case of both old and young trees, and besides being of good appearance is of very good quality. Mr. Gladstone is said in the catalogues to ripen in July, but we can only speak of it as an August Apple, and a very good one. It is large, handsome, very prolific, and excellent in quality; it merits planting largely as an early sort. Market growers, as well as private cultivators, would find it profitable. Irish Peach is another fine August Apple, too well known to need any special recommendation from me. Red Astrachan is a good variety which hardly ever fails to bear a crop. Devonshire Quarrenden and Duchess of Oldenburg are early August varieties too, but not specially high in quality so far as my experience goes. Kerry Pippin is a free bearer, small and crisp, and deserving more patronage than it generally receives. It is a useful October Apple, and will be found good in November or later.

King of the Pippins, although classed as an early variety, is not ready until November, and will remain good until March. It is a splendid Apple in every way. The yellow Ingestre is a distinct and good September and October, although it is not quite so highly flavoured as some of the others. Of new dessert Apples Bunyard's Lady Sudeley is a real acquisition. It ripens about the middle of August, is very handsome, large in size, excellent in flavour, and a great bearer.

CULINARY VARIETIES.—Early kitchen Apples are well represented by several very good varieties; the best known of these is the old Keswick Codlin. In my opinion it is still the most valuable of all. It is a free grower and great bearer in all quarters. The fruits are of good size, and when good perfect models of what a culinary Apple ought to be. It should be included amongst all orders for kitchen Apples, no matter how small the number may be. Lord Suffield is another of the same class, so far as quality goes. It is a free bearer of handsome larger fruits, but I do not find it succeed so well on gravelly soil as the Keswick. For exhibition in August and September it is unique.

It bears very freely in a small state, and I have seen trees not more than a yard in height requiring propping up in autumn to prevent the weight of the immense fruits breaking the branches. Mr. Gladstone may be included amongst the kitchen Apples. It is one of those which serve two purposes. Worcester Pearmain is a free-bearing variety with firm, finely formed, highly coloured fruit. The Hawthornden is one of the surest and best of bearers of capital fruit which may be used in August or until December. Wormsley Pippin is good for the kitchen or dessert. Stirling Castle is one of the earliest, medium in size, and a heavy bearer. Golden Noble is another which should find a place in all collections of any extent. It is ready in September, and not over until December. York-shire Beauty is a free bearer, and does remarkably well in the orchard. It is an August and September variety, and finishes my list of good early Apples. Later ones will be referred to in a future issue.—A KITCHEN GARDENER.

ROSE W. F. BENNETT.

VISITORS to the principal Rose shows have seen and admired boxfuls of the rich purplish crimson blooms and expanding buds of this floriferous Rose. But there are numbers of persons who delight in Roses, who cannot attend exhibitions of them, and there are also many who do not think it necessary that a Rose must be of sufficient size for including in stands of prize blooms to entitle it to be considered as meritorious. W. F. Bennett is not now referred to as an exhibition Rose, though it may be occasionally staged, but as valuable home decorative variety—a Rose for the million for supplying rich and beautifully formed half-expanded buds for cutting in profusion. This, when well grown, it will do, not only in summer but in winter in light moderately heated houses. It may be referred to as a perpetual-flowering Hybrid Tea Rose, and will form an admirable companion to the favourite white Niphetos, which in form it somewhat resembles. It is not unlikely that W. F. Bennett will become widely popular and be extensively cultivated for supplying the markets with flowers, and that, after all, is one of the best tests of the merits of a Rose. Messrs. William Paul & Son of Waltham Cross ohligingly enable us to publish a fair representation of the Rose in question, which was honoured with a first-class certificate by the Floral Committee of the Royal Horticultural Society two years ago. The stock was purchased by

Mr. Chas. F. Evans of Philadelphia, and Messrs. W. Paul & Son are appointed agents for the sale of plants of both W. S. Bennett and Her Majesty in this country. The Rose now figured was the result of a cross between President and Xavier Olibo by Mr. Henry Bennett of Shepperton.

SEASONABLE NOTES ON FLORISTS' FLOWERS AND SPRING BULBS.

AURICULAS.—I have just now removed my frames into their winter quarters facing the south. With me it is much easier to get a sunny than a shady position, and I have to be more particular about their

leaves have been taken off, and where necessary the surface of the pots has been stirred. I now and then detect a little of the woolly aphis, and when I can I remove it, although, as I have said, not so afraid of it as I used to be; still, I am sure it bodes no good to the plant, and ought, therefore, to be removed.

CARNATIONS AND PICOTÉES.—The rains which we have had since the beds of these were planted out has enabled them, no doubt, to root well, and all that they will require now is careful weeding and staking where the plants are at all long.

GLADIOLUS.—I have never been so late in harvesting these corms as this year. The wet weather came on just as they were dying off, and the ground has become so saturated that it is difficult to get them properly.

Fig. 62.—ROSE W. F. BENNETT.

summer position than their winter one. I have placed the frames in a good open position. The chief point I have to guard against is wind, for more than once when the frames have been left open they have come to grief. In looking through my frames I do not find more or as much autumn blooming as in ordinary years. I believe that the autumn has not been a growing one; I find, at any rate, that our farmers are all complaining that their autumn-sown seeds, such as Mustard and Rape, have not made much progress, and I have been surprised in the garden to find how late Chrysanthemums and other autumn-flowering plants are, while Belladonna Lilies have not yet pushed their way through the ground. Before placing the Auriculas in their quarters the dead

As a result of this I find fresh roots beginning to grow, a matter I should gladly have dispensed with; otherwise, the corms are "lifting" with me remarkably well, and my losses are fewer than usual. I have now some decent blooms, and they have thus for three months and a half given me much enjoyment.

DAHLIAS.—There has been in our locality as yet but little frost to injure these, although we have had very cold winds; they will, however, soon succumb, and must be taken up and stored away in a dry place. I hardly fancy the plan mentioned in last week's Journal will find much favour, but that the old plan of storing them away in a dry place free from frost will still be resorted to.

SPRING BULBS.—There surely ought now to be no difficulty in providing any garden with a good supply of these. When one sees the amounts of our great leading firms, the incessant sales at our auction rooms, and the temptations held out by growers in Holland to get them direct, they ought surely to be found everywhere. There are two ways in which they may be grown—one, leaving them in the ground always; the other, taking them up and storing them, and planting them in the autumn. It will be seen in the following notes that I adopt both of these plans.

CROCUSES.—I think the best way to grow these is as a border to the herbaceous beds. You may have clumps here and there of them, but they look gayest and best, in my opinion, as a bright border in spring. I leave mine in the ground for a few years without taking up at all, and have the edges of the border planted with the white *Campanula pumila*. This makes a green bed for them, through which they readily push themselves, and when they have done blooming and the foliage is tolerably yellow they are all cut off close, and the space occupied by them in spring is quite gay in the summer with the *Campanula*.

HYACINTHS.—Here also I have no planting in the autumn, or at least very little. My plan, as I have stated, is to plant out each year those I have grown in pots and then to leave them; by this means I have all over my garden clumps of them, which give fine blooms. When they have to be planted it should be done at once, as I see some I have just had from Messrs. Cutbush & Son are emitting roots, showing that it is quite time for them to be in the ground. They can now be had in various colours, guaranteed to bloom at the same time; so if a simultaneous bloom is wanted these are the best to obtain. I, however, prefer them to come on in succession, although the named varieties are of course more expensive than those which are to be obtained in colours. I do not think that the *Hyacinths* will refuse to do well in any light garden soil.

TULIPS.—The early-flowering varieties of these, as they are called in contradistinction to the florist varieties, make a very showy appearance in the garden. I have a large bed which I always use for them, manuring it well in the autumn before they are planted, and they grow and flower well. After they have done flowering they are taken up and dried, and the bed is planted with *Marvel of Peru*, which blooms until very late in the year, and scents the whole place of an evening. The following varieties are showy—*Bird of Paradise*, yellow; *Chrysolora*, large pure yellow; *Etna*, crimson; *Rose Luisante*, bright rose; *Vermillion Brilliant*, rich vermilion; *Couleur de Cardinal*, flamed scarlet; *Kaiserskroon*, yellow striped with red; *Proserpine*, rich rose; *Rose Gris de Lin*, delicate rose; *Globe de Rigaut*, purple, white streak; *Wouverman*, rich claret; *Yellow Prince*, rich yellow. I do not grow the double Tulips, as I think them inelegant and quite unworthy of a place alongside the single ones; others think differently, and the same treatment is available for both.

DAFFODILS.—The rage for these has become so general that there is no need to insist upon their desirability for the garden in spring, the great difficulty being amongst the very large number of varieties, or so-called varieties, to select those which are most suitable. They are amongst the easiest grown of all bulbs, and the only question with me about lifting them is they so soon begin to occupy too large a space, but there are a few that are sure to be favourites with everybody. The beautiful little *Hoop Petticoat*, with its citron-coloured variety; the grand *Emperor and Empress*, the much-talked-of *Sir Watkin*, and the chaste *Poeticus* ought to find a place in every garden; but with regard to others, the best way, I fancy, is to put oneself into the hands of one of those nurserymen who have given special attention to the matter, and obtain from them according to the extent of the garden what they would consider the best; once established they give very little further trouble.

SCILLA SIBERICA.—This beautiful blue-flowering spring bulb has been so largely propagated of late years that it has become a much cheaper article than it used to be, and for a few shillings a good quantity may be obtained. Planted in clumps or used as a border it is equally effective, and easily accommodates itself to most garden soils. Its worst enemy I find to be slugs, which are in the habit of eating off the young flower bulbs. This I find especially to be the case with those planted on the rocky, the slugs always finding good shelter under the stones. I have been but little troubled with them this season.

CHIONODOXA LUCILLÆ.—This charming blue-flowering bulb is now much reduced in price, as, indeed, it ought to be. There is no bulb which seeds more freely than it does, while it also increases rapidly. I planted a good many some years ago in clumps in the border fronting my greenhouse, and these have now greatly increased in size. I have noticed each year the self-sown seedlings all round the clumps, and I believe that these flower the following year, while the older ones have increased in strength so much that good spikes of bloom, carrying eight and nine flowers on the spike. It puzzles me very much that some people should try to disparage it by comparing it with *Scilla siberica*. With the exception that both flowers are blue there is no point of comparison between them. The *Scilla* is of a metallic steel blue, the *Chionodoxa* cerulean with white centre. I will not say that both have equal merits, but both are indispensable. I have found *Chionodoxa* later in its period of blooming than *Scilla*. It, too, is easily cultivated; in any good garden soil that will grow bulbs at all it is sure to do well. It does not require deep planting.

SNOWDROPS.—These universal favourites are too well known to need anything to be said in their commendation. They used to be considered, as their name implies, the earliest of all our spring flowers; but that must be conceded now to the *Cyclamen*, whose pretty flowers of white and crimson I have found to be far ahead in this point of the *Snowdrop*. Any

who have not already obtained it ought to grow the *Asia Minor* one—*Galanthus Elwesii*, which for size and beauty is far ahead of our old favourite, the common *Snowdrop*. I do not think there is much difference in point of earliness, and it is also very free in seeding, so that I have found it in my border springing up in all sorts of places; and I do not think, when once it is established, much thought will be given to the older variety. It is very constant, for I have never found the least variation in any of the seedlings.

There are several other spring bulbs which are worthy of attention; but they belong rather to the rock garden, such as *Iris iberica*, *Anemone apennina*, and *A. stellata fulgens*, but those which I have enumerated are bulbs for every garden, and those who have not already obtained them should lose no time in doing so. Let me just say that I have a good many of those mentioned in a border facing my greenhouse. Here are *Daffodils*, *Snowdrops*, some *Crocuses*, and *Chionodoxa*, and when these have all died down the ground is sown over with *Mignonette*, and a fragrant bed is in full vigour all the summer months and late into the autumn, thus avoiding the unsightly appearance of bare beds for long together.—D., Deal.

EXHIBITING GRAPES.

"J. W., *The Elms*," in his note on exhibiting Grapes might have gone a little farther and told us what he would have to meet his case. Now-a-days most exhibitors are working gardeners, though of course there are a few exceptions; but I suppose most of the Grapes exhibited are sold. Perhaps providing a class for single-handed gardeners or where a man and boy are kept would have been more to his idea. I have sometimes thought if classes were provided for two or more bunches of Grapes to be cut either from a given Vine or number of Vines in a certain space it might answer. A single-handed gardener, to my knowledge, has frequently a better opportunity for growing Grapes than the head gardener in large establishments; and "J. W.," must take courage and try his skill at one of the forthcoming shows, and then he will perhaps see for himself that he has as good a chance as the men he speaks of. At one time I thought market growers should exhibit in classes alone, but what is the difference between them and the noblemen who dispose of their produce in the same market? Personally, if I mean to show, no thought or fear of duke or lord, or any man in fact, would deter me from doing so, even if I knew they would defeat me. It would be a very poor show indeed if only just sufficient were staged to obtain the prizes offered. I like to compare side by side the good, bad, or indifferent points, and see what is to be learnt from it. Success in exhibiting is not only a question of £ s. d., but also of instruction. A stranger at a show of course feels somewhat lost at first, but my experience is that he has no need to be strange long at such places, for even in staging, a brother gardener, while doing his best to excel, will always hold out the right hand of fellowship.

I have known men to be very successful at very large exhibitions in good competition, when their stock of Vines was limited to a single house. It is not the size of the establishment, but rather the man that puts his mark on the Grape-growing. Legitimately encourage Grape-exhibiting by all means; to do this the fewer restrictions the better.

Now a word to employers of Grape exhibitors. In my younger days I was told that exhibiting meant so much loss in weight of crop, &c., which is quite a fallacy, for I can honestly say that a good moderate crop will produce better Grapes than a light crop. The latter will be very disappointing when show time comes. A word also to the grower. Do not oppose the wish of your employer. Of course it is the best you want for the exhibition table, and unless you all sail together keep the Grapes at home.—STEPHEN CASTLE, *West Lynn*.

MAIDEN TREES OF PEACHES AND NECTARINES

I CANNOT lay claim to any long experience with the system of planting maidens in preference to the trained trees which not long since were invariably employed whenever old trees had to be supplanted by young ones, or when totally new sites had to be furnished. These trained trees, it must be conceded, were very frequently grown into fine specimens, many of which existed for a long period, and, as a rule, they were much more perfectly formed than are the trees cultivated by the present generation of gardeners. Very few, if any growers, nowadays, expend much time in the attempt to secure a perfect outline, and which after the years occupied in its maturation, may be completely marred by the loss of one or more main branches in one season. It is now felt to be much too slow and unprofitable, and the aim is, as it should be, to furnish the walls or trellises, as the case may be, as expeditiously and cheaply as possible; tree worship in its old form thus taking a much more practical shape, to the advantage of all concerned. Probably perfectly formed trees are as much admired now as they ever were, but we judge by results rather than appearances.

One great result of the improved system of pruning and training is the rapidity with which a house may be furnished with fruitful trees, and which trees, owing to the more intelligent methods adopted, are undoubtedly much less liable to gumming and consequent loss of important limbs and branches. In a

great many cases the trained trees supplied by nurserymen have been irreparably injured before they have left their hands; not, however, from any carelessness on their part, but simply owing to the faulty practice adopted. The wounds caused by the severe pruning may have healed, but the dead wood covered by the new bark will in time make its pernicious effect felt, and the tree gradually, but surely, decays. Even if this be an exaggerated evil, the fact remains that in these frequently hard-pruned trees there are branches that have failed to keep pace with some of the rest, and these in time become "hide-bound," or refuse to swell proportionately with the younger growth beyond, and this again results in a collapse. Those who wish to avoid these dangers will do well to purchase maidens—that is, young trees that have never been cut back, and start with these in preference to those that have been hard cut back two or three times, and which are known as trained trees. Not only are they very much cheaper to start with, but they can be got into full bearing almost as quickly as the trained trees. I say almost, as I do not go so far as some may be inclined to do, for the simple reason that the rapid extension system may also be equally as well adopted with the trained trees, but I prefer the maidens all the same.

No difficulty will be experienced in procuring maidens by those who require them, as the nurserymen would rather sell a tree at 1s. 6d. that would have to be grown two or three seasons longer, requiring to be pruned, trained, and replanted each season, and then only realise 5s. Maidens can be procured readily enough, even of the newer sorts, and which cannot be supplied as trained trees, but it is not the extra strong trees that are wanted, as nurserymen seem to imagine, but medium-sized, well-ripened ones, and which should be stipulated for. The former will have branched considerably, and as these laterals are not fit to lay in, the chances are, a considerable, perhaps the best, portion of the stem will be blind, whereas the medium-sized trees will not have pushed many of the lower buds, and these will be available for next season's break. Further, these strongly grown maidens are apt to produce a few very gross shoots, and these require more skill in their regulation than many beginners would bestow on them. Mr. Taylor, when at Longleat, used to insist upon having these moderately strong well-ripened trees, even if he paid more for them, and since I have taken to planting maidens, I have good opportunities of learning why they are so much the best.

There are two methods of treating these maidens, one of which may be termed scientific, and the other the unscientific; and the difference is, by the former a tree may be trained to almost, or quite as handsome proportions, as by the old restrictive system, while by the other a less handsome tree will be secured, but this will perhaps have the healthiest stem, and may live all the longer in consequence. I may be wrong in the latter surmise, but appearances in the case of our trees point that way. What I term the scientific system has been well advocated by Mr. Simpson of Wortley, who in his work on Improved Training recommends that the maidens be cut down when first planted, say to within 4 inches of the union of the bud with the stock, two only of the shoots resulting, one on each side being retained. These shoots, carefully laid in obliquely, will, during the same season, form numerous laterals, but only two of these are laid in, both on the upper side, one near the base, the other one from near the middle of the shoot, the remainder being pinched beyond the second leaf and kept closely stopped during the summer. In this manner a healthy tree will have perfected six well-placed, and, if the other conditions are favourable, well-ripened main branches. Then if these branches, or the ripened portion of them, are laid in to their full length, any number of well-placed shoots can be trained from them, those not required, including all with a foreright tendency, being either rubbed off or kept closely pinched back. As Mr. Simpson states, and which I can fully corroborate, "a comparatively large tree" under this intelligent treatment can be secured in two years, and which will, in many cases, perfect a crop of fruit the following season. It is not always, however, quite such an easy matter to form a well-balanced head as I appear to suggest, so much depending upon circumstances. Given a healthy maiden to start with, and a good open position, either in a house or against a sunny outside wall, in which to plant them, and there need be no great difficulty; but when the maidens have to be planted among well-established trees, or if they are merely stuck into an odd corner with little or no preparation made for them, the case is very different, and the progress the trees make will be very slow indeed.

What promises to be the best trees on the place were bought as maidens and not cut back beyond trimming off the lateral growth and shortening the leader to within about 18 inches of its base, this preserved length of ripened growth eventually

becoming the main stem of the tree, whereas in the case of the cut-backs it is divided into two main branches, and which are not always so well balanced as we would wish them. I find that where the slightly shortened maidens broke evenly and healthily, as many as seven shoots were laid in, and these are now the main branches of the tree. At pruning and training time most of these branches were laid in to their full length, and from each, as many young shoots were subsequently trained as were required to form the tree and cover the space. Those grown under glass from the first made the least sappy growth, and gave a few fruits the season following planting, while during the second season the best perfected about three dozen of fine fruit. A tree of Alexandra Noblesse planted early in 1882, at the end of 1884 fully occupied a space of 12 feet square, and during this summer perfected seven dozen of fine fruit. I am aware that this is a poor achievement in comparison with what others have done in a less time, too, but then our maidens had to be grown in forcing houses among old trees, and were at a decided disadvantage, especially at the outset.

Even with the unscientific system which I have tried to explain, the beginner will have to use some judgment, especially in the regulation of the branches, or a "one-sided" tree may be the consequence. Some of the branches are apt to assume the lead—grow much too strongly in fact—this resulting in the harmful weakening of the remainder. If these gross shoots are allowed to have their own way for one season, they will always retain it, or if, when too late, are cut hard back, the next breaks will be still more gross, and the tree be spoilt. If any of the very sappy shoots that are produced cannot well be completely removed, they must be checked, so as to divert the flow of sap to those branches most requiring it. Mr. Simpson recommends "pinching the points during the growing season of those that are taking the lead too much till the others overtake them," while another experienced grower removes a considerable number of leaves from those shoots tending to grossness, this effectually checking them, and both plans are good. When the trees are altogether too vigorous to be fruitful—and it is astonishing how very strongly some of them will grow—they must be lifted and root-pruned in order to give the necessary check. This is more necessary in the northern counties than with us in the more favoured south, and I am informed that in some districts what I consider medium-sized well-ripened growth, would be termed coarse, and would not be fruitful in the counties of Durham, Cumberland, Westmoreland, and other moist localities. In our case, most of our maidens intended eventually for the houses are prepared for one or two seasons on the open walls, and the check given to them when transplanted is all that is required to make them fruitful. Once in full bearing, these freely grown and but slightly pruned trees give every evidence of long remaining in a healthy profitable state, very different in fact, in our case, to trained trees bought at about the same time. In a very short time they will have stems quite as large as have those trees that are four times as old, and which, do what we will to prevent, are frequently losing some of the best branches. The latter are being gradually replaced by healthy young trees originally bought in as maidens, and the change will certainly be to the benefit of all concerned.—W. IGGULDEN.

THE WOODS IN AUTUMN.

I FEEL I owe something to the Journal, and have owed this for a long time. Many people have also asked me why I never write to the Journal now, and some friends have expressed a wish that I should write once more to you on the subject of our woods. I am afraid I can write nothing new, but your readers perhaps will forgive me if this paper is dull and uninteresting, and give me credit for at least good intentions.

We are now in mid-autumn, so far as the calendar is concerned, but so far as Nature is consulted there are here in this western county but few signs of it. The moisture in our air is so great that the leaves on the trees seem to retain their freshness much longer than those nearer town. We certainly are much later in coming into full bloom, but we make up for it in autumn.

Will you take a walk with me through the great wood which surround our church? I have recently made a grand ride, which traverses one side of it from end to end. The wood is in the form of a huge horseshoe, and a more lovely one I do not know. There is a farmhouse at each end of it, and the walk connects the two. The ride is made right through the middle, and rises and falls with the nature of the ground, and all along it most lovely views open out. The Oaks are the great feature, not grand giant Oaks like we find in Warwickshire, but moderate-sized ones, but oh! so beautiful. Many of the branches of this one have been injured by the storms, and hang half drooping, half erect. Here you can see but faint signs of decay, still the leaves are green here and there, like on the locks of a man who has passed the prime of life. Signs of winter appear, a few leaves are tinged with yellow, and a deeper russet colours the topmost branches and those that face the sun; but the general tint is green, though

of a sober dark hue. Here let us notice the wonderful contrast the Ash affords. Its leaves have the bright glaucous green tint which they have at the height of summer. No tints are to be seen here, and my experience leads me to believe that the Ash leaves change less than any others.

As we walk along we see, however, most glorious coloured leaves hung with the blackest of fruit. The common Blackberry now is almost as deep coloured as the Virginia Creeper. It is a most lovely object, though the fruit, luscious as it looks, is almost worthless. There is an old saying that the Blackberries are never worth eating after Michaelmas Day. As all these sayings refer to the old reckoning on old Christmas and old Michaelmas, we must add on twelve days to our calendar, and so old Michaelmas means the 11th of October. After my work was over on old Michaelmas Day, which was a Sunday this year, I went through our wood with members of my family better able to judge on such matters, and they all agreed that the Blackberries were flavourless and sour, but the leaves are now most lovely. Soon we came to the Mountain Ash, already bearing scarlet berries. Even the Holly is now covered with red berries, reminding one of the old saying, that when the Holly has many berries we are sure to have a hard winter, but this I have disproved for many years. But what a walk it is! and how quiet and peaceful Nature is this afternoon! As we left our house the wind seemed high and felt cold, but here it is quite still. No branch moves, scarcely a leaf flutters. Nature's work is done, calm decay awaits her. Already signs show that this has commenced, but meanwhile she rests: a hush is over the woods, the birds are quiet, no sound of music steals through the Oaks. Now and then a wood pigeon the shyest bird I know, breaks out from its roosting tree with a loud noise, but only flies to another part of the wood, and no small birds are to be seen.

Rabbits, however are here scuttling about as they are disturbed by our footsteps, but they make not the slightest noise. All speaks of peace and repose. But soon as we near the end of our walk we hear the music of the little brook that rises in our wood. And here all along the walk are the glorious Ferns, the common bracken. Ah! no mistake about the season here, the bracken fronds are quite brown and almost dead. Nothing shows the close of summer more plainly than the common bracken. And, alas! something else shows it in a very unmistakeable way; it is not yet six, and already the shades of evening are gathering fast. The dew is rising, the air is damp, the sun has set, and we conclude our walk in the lovely twilight.—MONKTON WYLD.

NOTES ON THE PLANT STOVE.

THE dull time of year is now rapidly advancing, when great care will have to be exercised in the plant stove. No more pottings should be done then is absolutely necessary. Alocasias cannot be increased too much, as nearly all are well worth growing. Alocasia Thibautiana makes a fine plant for exhibition, but it gets rather tall. In such cases get some sphagnum moss and tie it neatly round the stem, so as to encourage it to throw out roots. Syringing may be carried on at present, but on dull days it will be better to do so only in the morning. The sponge will be needed more than the syringe now. Alocasias and Anthuriums should be sponged about every three weeks. Three or four of the best foliage Anthuriums are *A. crystallinum*, *A. Browni*, *A. Veitchii*, and *A. Warocqueanum*.

Achimenes and Gloxinias must be stored away in a warm dry place until the time for starting them into growth again. Asparagus plumosus nanus is very apt to get infested with a very small white scale, but syringing with petroleum and water will soon destroy it. Caladium argyrites is one of the best plants for decoration either for the plant stove or for table decoration, and where there is a stock of bulbs they can be kept growing all the year round. A good companion for *C. argyrites* is *C. minus erubescens*.

Calanthe vestita is now pushing up its flower spikes; a few of them should be placed in more heat so as to force them into flower earlier. A good plan (where there is a lot of Maidenhair Fern grown) is to place one pseudo-bulb in a 48-sized pot, so that when they are in flower the pot can be put underneath the Fern with the flower spike drooping over it; this has a very pleasing effect.

Crotons may still be kept well syringed twice a day, and about once a fortnight with a mixture of petroleum and water. If so treated there need be no fear of thrips, nor yet of the small scale which infests Crotons when they are not doing well. Curculigo recurvata variegata will be useful during the winter; it will grow well in either stove or intermediate house; it is increased by suckers. Sponge Dracenas, chiefly on account of water getting into the axil of the leaf, which will soon cause them to decay off. Dieffenbachia and Ixoras are much infested with insects, the former being subject to green fly and the latter to both fly and thrips. It is better not to fumigate if there are any Orchids in the same house, as tobacco smoke is very injurious to the foliage of some Orchids. Fittonias, Panicum variegatum, Peperomia, Phyllotænium Lindeni, Sonerila, and Tradescantia should be increased as much as possible, for if only in small pots almost any variegation looks pleasing in the winter. Also any small suckers of Pandanus taken off now and inserted in the propagating frame will make good plants by next summer.—A WORKER.

IN THE VALLEY OF THE WILBERFORCE.

UNDER the above title Mr. F. N. Adams sends us an article describing a botanical visit recently paid to that district of New Zealand in company with Messrs. Brown and Arnold, and from this we take the following

extracts. The article appears *in extenso* in the *New Zealand Country Journal* for September.

"We made an early start next morning, passed the swamp fed by Lake Georgina, which lies in the hollow between Mt. Barker and a hill on the right, Craigieburn range in the distance. The river Rytton comes next, some 100 feet below; travelling downhill being a welcome change from the previous uphill work. This river draining the spurs of the Craigieburn range was very low, but in spring it would be hard to cross even on horseback. To the left was the carriage road range, hiding the 'gloomy Lake of Coleridge,' but we caught an occasional glimpse of the water through the spurs. Swamp hens were numerous in the boggy ground, and we saw Paradise ducks on Lake Selfe, which is about three-quarters of a mile long by one and a half wide. The lake has a grand natural background—the snow-covered peak of Mt. Gargarus in the distance; in front, tussock-clad hills with a fringe of bush, principally Fagus, Veronica, Olearia, Cassinia, bare rocks and jagged peaks jutting up here and there. When we arrived at the Harper it was in slight flood, one branch being 2 feet deep. Stayed at Fisher's wharf all night in company with Mr. King, who had helped us across the Harper. The weather looked threatening next morning, and we crossed the first branch of the Wilberforce in the teeth of a nor-wester. The road on the island is very rough travelling over stones and tussock; posts mark the route to the Government hut, where we made a short halt for refreshment. After leaving the hut we had a few miles of shingle, then the main branch of the Wilberforce and several small streams to negotiate before we could reach the flat at the mouth of the Moa river. This flat is a patch of good fertile land. Here were collected the large seed capsules of Mimulus radicans, and the purple berries of Pratia macrodon; patches of Celmisia spectabilis covering the road. Crossing the Moa river, which runs very swiftly, we took the newly formed road through the bush up to the camp, which we heard was six miles up the river at the junction of the N. Creek. As we passed through the zones of Beech, Celery Pine, and Pitch Pine, we saw the smoke of a fire ahead, which proved to be the camp of the roadmen. About two miles farther on we saw the light of the Moa Creek camp, and crossing the Moa again on a tree thrown across it we soon found ourselves among tents, whares, &c.

"Mr. Landers welcomed us with the true hospitality which the dwellers in tents have always given to the stranger, and the cook put before us a substantial meal, which came to the famished botanists like manna in the wilderness. Slept like tops in comfortable camp beds, and next day we met with Mr. Slater, a prospector, who knew the country. He took us over the Moa river, and showed us the habitats of Gleichenia Cunninghamii and Dracophyllum Traversii. This Epacrid grows 80 feet high, towering above the other parts of the bush, its long branches extending horizontally, bearing a tuft of leaves at the extremity, from which rises the bloom like a Pine Apple. It is certainly the most remarkable tree of the Alpine flora. Many young specimens were collected; those about 2 feet high are very handsome, with filiform leaves drooping like a Dracana. There is another variety, *D. longifolia*, but its leaves are smaller and more imbricated. The tree was met with up to the snow, so that its hardy character cannot be doubted. The prevailing timber tree on Moa is Libocedrus Bidwillii, the Incense Cedar, the Kawaka of the Maoris. The tree attains to 30 or 40 feet in height, its conical top and dark green foliage being visible above the surrounding bush. The bark, which peels off easily in spring, is utilised by the miners in various ways. Like all Cedars, the wood is dark red and splits readily into slabs, but as the centre of most of the trees is hollow, and the wood very soft, it is not of much value as timber. It is singular that the wood of the other variety, Libocedrus Doniana, which grows in the North Island, is hard and valuable. The Ribbonwood, Plagianthus betulinus, is easily distinguished from the surrounding forest at this season by its golden leaves: the tree is deciduous, and its leaves had been touched by frost.

"On our return to the North Creek we separated; my companions taking different routes, but I had definite objects in view, and in company with Mr. Slater went in search of Ranunculus Godleyanus. Mr. Landers told us that the yellow Buttercup grew at a considerable elevation up the North Creek, so we made a start in that direction. Following that creek, which flows into the Moa river a few chains above the camp, on either side were spurs of the Cascade range covered with forest up to the snow-line; at intervals were small waterfalls pouring over precipices among the large boulders which had been rolled down the creek. Ranunculus Lyalli was plentiful on the banks, Veronicas lined the margins of the bush, while fine specimens of Angelica gingidium occurred some 2 feet across. The miners called it Aniseed, because the leaves and seed have a similar flavour. Horses are very fond of this aromatic herb and eat it greedily. Crossed the North Creek on a temporary bridge which led to the reef, on the slopes of the mountain; it is situated 1600 feet above the creek, and can only be worked in fine weather; in winter the claim would be covered with snow. Leaving the track we followed the bed of the North Creek, climbed very big boulders, and crossed the creek several times. When not in flood this creek is about the size of the Avon, but when there is a fresh it is a mountain torrent, tumbling over boulders and washing everything before it. Dracophyllums grew on the slopes in abundance, their peculiar heads standing up clear of the bush. Passing No. 2 creek we saw Mountain Lilies growing under the side of boulders and burnt scrub, whilst others grew on the vertical faces of rocks, the roots wedging themselves into the crevices. Ourisia macrocarpa grew in patches 2 or 3 feet across—its bold dark green foliage, purple underneath, and large trusses of white flowers rendering it one of the finest of Alpine herbaceous plants. We found the best patches growing in peaty soil with water trickling among their roots, on the sides of watercourses. The other variety, *O. macrophylla*, we found growing in similar situations but the leaves and blooms are smaller. Some fine plants of Aciphylla Mourou, 8 inches high, were noted, evidently the male variety. The scenery, up the creek baffles description; ahead there is Mt. Mystery, to the left Mt. Williams with its ragged-looking peaks sticking out of the snow, and on the right mountains covered with forest, the creek between. We had some hard climbing to reach No. 5 creek, where the rare Aciphylla with red midribs and spines was met with. Half a dozen specimens were collected. A large Aciphylla with dark green leaves grew among the boulders. Carmichaelia odorata was apparently very local, as it was only met with once in No. 5 creek; it was out of bloom, but the miners said it

scented the air in the summer. Straggling plants of *Eileiweiss*, *Helichrysum grandiceps*, now appeared, showing that we were not far off the yellow Mountain Lily. Scrambling over some loose boulders we caught sight of what appeared to be *Ranunculus Godleyanus*, about 300 feet above. Everything was frozen, and plant-collecting at 5000 feet is not very nice work, hands and feet being so benumbed with cold as to be almost useless. *Celmisia coriacea*, the Cotton Plant, grew in abundance at this elevation, its silvery foliage and graceful habit making it a very pretty plant. Of *C. petiolata* we saw a few plants growing in boggy ground. In shady places, *Ranunculus Lyalli* was in full flower, and on one plant there must have been fifty expanded blooms. Several smaller varieties of *Ranunculus* grew among the stones. We at length reached *R. Godleyanus*, named after Mr. Godley, the pioneer of Canterbury. It has dark green foliage with shining yellow flowers borne on flower-stalks like *R. Lyalli*. With a prospector's pick we dug the plants out of the shingle slide, composed of broken slate, water continually running at their roots from the melting of the snow above. As the plants were covered with snow and ice it was difficult to get them out even with the help of the pick. Some very fine specimens of this rare plant were collected, but as the sun was going down and it was freezing hard we decided to commence the descent. We had several miles of very rough country between us and the camp, which required daylight to travel over in safety. The prospect of spending the night in that Alpine region without tent or food *à la* Mr. Green and his guides at Mt. Cook, was not pleasant, so we came down at top speed. In No. 5 creek we saw the large white flowers of *Veronica macrantha*, also a new *Gentian* with white flowers and pale green leaves in the shape of a rosette. Both seed and plants were collected. On the way to camp a variegated sport on a plant of *Senecio Bidwilli* was secured for grafting. Arrived at camp at 7 p.m., heavily loaded with plants and about twenty varieties of seeds which were collected during the day."

(To be continued.)

MARDEN PARK, CATERHAM.

THIS is Sir William Clayton's Surrey seat, but is at present rented to W. L. Greenwell, Esq. It is pleasantly situated some seventeen miles to the south-east of London, and nearly three miles from the little village of Caterham Valley. The old house was burnt to the ground some six years ago, so the present house is a modern erection built in the Elizabethan style, and is within a mile of Marden Park station on the London, Brighton, and South Coast Railway. The Park covers an area of 160 acres; and is entered by two neat porters' lodges, one on the east and another on the west side of the house, which cannot be seen from any points until the visitor is close upon it. The position of the house seems low, but I was informed that the front doorsteps and the top of St. Paul's Cathedral were on a level. The immediate surroundings of the house—some four acres in extent—are beautifully laid out with clumps of choice shrubs and Conifers, the margins of which are kept gay with a miscellaneous collection of herbaceous and bedding plants. Most of the trees throughout the Park are of great antiquity; very notably were some clumps of Yews, Limes, Beeches, and Chestnuts. Of the two latter I question much if there are finer individual specimens in England.

After admiring these gigantic trees we proceeded to the gardens by the principal walk, which is conducted through "Cedar Lawn," deriving its name from three grand old Cedars, said to be more than 200 years old. The garden is situated at the foot of a hill in a sheltered position, beautifully embosomed in the wood and sloping to the south. It is surrounded by a good brick wall 10 feet high, containing an area of four acres within the wall and a portion of the ground without. The walls are fairly covered with Peach, Plum, Pear, Cherry, and Fig trees. The latter ripens its fruit well on a south wall. The kitchen garden is divided into several quarters by 8-feet walks with Box edgings, and fruit trees are planted along the sides of the main walks, and in many places they have met and form a perfect bower, the trees affording more of a shade from the sun than they do in the way of filling the fruit room. Several younger trees having recently been lifted and replanted on slightly raised mounds of fresh loam were carrying fine crops of excellent fruit. Conspicuous amongst the Apples were Warner's King and Quarrenden. The above varieties seldom fail to bear well at Marden.

Small fruits are well represented by a selection of the leading varieties. Raspberries were planted in rows 6 feet apart and trained to a wire trellis. The canes were extra strong, ripened as brown as a Hazel, and cannot fail to produce a heavy crop next year. The culinary department was well stocked with excellent vegetables; particularly fine was Asparagus and Celery. Violets are also grown extensively at Marden. Mr. Clingen informed me that he was rarely without Violets, and he attributes his success to annually layering or pegging down two, three, or more runners from each plant and allowing them plenty of room. The old and woody crowns by this system are cut out annually, and fine blooms are obtained from the young plants.

The fruit and plant houses are built on a steep slope at the north of the garden; though they are old they are in fair repair. On entering them from the west No. 1, a lean-to vinery 40 feet long by 16 feet wide, with borders both outside and in. The varieties grown are Black Hamburgh, Buckland Sweetwater, and Foster's White Seedling. The Vines in this house have only been planted four years, and the fruit was all cut at the time of my visit, but the fine foliage and well-ripened wood with plump buds indicated excellent crops. We next entered a three-quarter span-roofed conservatory 60 feet long by 20 feet wide. This house contained many fine specimens plants, amongst which were some fine Orange trees 16 feet high, and in most luxuriant health. A fine *Seaforthia elegans*, Palm, and some grand Azaleas. Four plants of *A. The Bride*, 6 feet high and nearly as much through, were in the best of health and bristling with buds. Tuberous Begonias were also very fine, especially

Princess of Wales, Princess Beatrice, Empress of India, and Albert Crousse. Specimen Fuchsias were also well represented by many of the leading varieties. The roof and pillars were covered with *Tacsonia Van Volxemi*, *Plumbago capensis*, *Rhynchospermum jasminoides*, and *Fuchsia Mrs. Gaddick Ditton*, a variety well adapted for covering pillars. The gardener's house and young men's rooms, fruit and storerooms, are built at the back of the range. Like the hothouses they are old, but nevertheless they are commodious and convenient.

We passed along 100 yards or more to the east and enter a cool fernery, 24 feet long by 10 feet wide. Most of the Ferns are planted in receptacles made purposely for them. Next to this is a span-roofed plant stove 40 feet long by 12 feet wide, with a sunk passage up the centre. This house contained a choice collection of fine plants. The following have been most creditably managed by Mr. Clingen:—*Davallia Mooreana*, 6 feet through, and two grand plants of *Adiantum concinnum latum* and *A. gracillimum*, *Epiphyllum truncatum* 3 feet through, and some fine specimen plants of *Croton angustifolius*, *Bougainvillea glabra*, and *Asparagus plumosus nanus*. Besides these were a good assortment of Palms, *Dracenas*, *Dendrobiums*, *Cypripediums*, *Oncidium*, *Laelias*, *Calanthes*, &c. The roof was covered with a fine plant of *Stephanotis floribunda* growing in a 15-inch pot, which was flowering profusely.

We next entered the early Peach house 36 feet long by 12 feet wide, three trees being planted in front on turnover trellis, with three standards on the back wall. The varieties grown are Royal George, Bellegarde, Barrington, Noblesse, and Elruge Nectarine, all of which were in the best of health, and was informed that they seldom or ever fail to bear heavy crops. There was also a very fine crop of Tomatoes growing in 10-inch pots in this house. The late vinery comes next. It is 30 feet long by 12 feet wide, with borders outside and in. The varieties grown in this house are Muscat of Alexandria, Gros Colman, Black Alicante, and Black Lady Downe's. The two latter varieties were all that could be desired in size of bunch, berries, and general finish; seldom have we seen finer Lady Downe's. Gros Colman was also remarkable for size of bunch and berry. Some fine Caladiums were in this house 4 and 5 feet through. We next enter a Peach case 70 feet long, with a division in the centre. This case was filled with fan-trained trees, which were carrying a fine crop of small but highly coloured fruits.

In the nursery ground were many useful frames and pits. Melons and Cucumbers are well done on beds of fermenting material. The former were nearly over at the time of my visit, but Cardiff Castle Cucumber was bearing freely, and as a frame variety Mr. Clingen looks upon it as a real cut-and-come-again sort. The most of the frames were filled with a good collection of useful plants for winter bloom, which were in the best condition possible. To the east of the garden is a fine old orchard in grass, well stocked with standard fruit trees, most of which were carrying heavy crops. The whole place is conducted with skill and ability, reflecting much credit on Mr. Clingen, who has during the last seven years made great improvements in the gardens with a very limited share of assistance.—A. SMITH.

CHRYSANTHEMUM SHOWS.

SURREY CHRYSANTHEMUM SOCIETY.—NOVEMBER 2ND and 3RD.

THE second annual Show of this Society was held in the Public Hall, Rye Lane, Peckham, on Monday and Tuesday last, being the first on the long list of exhibitions for the present month. The date being fixed so early it was scarcely expected that a very satisfactory display would be obtained, but the result was an agreeable surprise. There was not a large number of entries, but those who did exhibit had some blooms and plants of considerable merit, the former being especially interesting, as no dressing was permitted. The groups were also good, Mr. G. Stevens of Putney winning the prize of the Show (a silver cup, value five guineas) with a superb collection of plants most effectively arranged, and comprising a suitable proportion of both incurved and Japanese varieties. Some handsome blooms of Elaine and Mademoiselle Lecroix were very conspicuous, as were also those of the bronze yellow free-flowering Japanese variety Mrs. Stevens, of which numerous plants were employed in the group. Mr. Stevens also gained the first prize with twenty-four incurved blooms, distinct varieties, none of which had been dressed, and very few could have been improved by any such artificial treatment. Mr. T. Sadler, gardener to C. Lambert, Esq., Oak Hill Place, Streatham, was a very successful exhibitor, carrying off five first prizes, besides several seconds. His twelve incurved varieties included some beautiful blooms of Prince Alfred, Golden Emperor, Queen of England, Prince of Wales, and Mrs. Dixon, while his twelve Japanese were all extremely handsome, comprising the following:—*M. Astorg*, a magnificent bloom; *Margot*, *Mdlle. Lecroix*, *Mad. C. Audiguier*, *Thunberg*, *Rubrum striatum*, *Elaine*, *Curiosity*, *Peter the Great*, *Mons. Tarin*, *Soleil Levant*, and *Bouquet Fait*. Mr. Sadler also had six *Anemones* of good size (a fine group of plants), and six trained specimens, all of which were very creditable to his skill as a grower. It may be remembered that the wonderful bloom of Elaine shown a week or two ago at South Kensington came from the same garden. Some of the best of the other exhibits came from Mr. Haynes, gardener to Jno. Chandler, Esq., The Terrace, Champion Hill; and Mr. Howe, gardener to Mrs. Fletcher Bennett, Tulse Hill House. The Committee and Secretary, Mr. R. R. Priestley, have every reason to be satisfied with the success of their second exhibition.

EALING.—NOVEMBER 3RD and 4TH.

THE usual annual autumn Show of the Ealing and District Horticultural Society was opened at the Lyric Hall, Broadway, on Tuesday and Wednesday last, and proved, both as regards the number and quality of the exhibits, highly satisfactory. The specimen Chrysanthemum plants were the weakest portion of the display, as the date had evidently been too early for the growers to get them into the best condition, but the cut blooms were remarkably good in several cases. The groups were arranged near the walls

and the blooms occupied tables in the centre of the hall, a graceful group of miscellaneous plants from Mr. Roberts, Gunnersbury Park Gardens, occupying a prominent position at one end of the building. A room was also devoted to the Apples, vegetables, and Potatoes, in which classes there was keen competition. Several miscellaneous exhibits, especially the Apples and Chrysanthemums from Messrs. C. Lee & Son, Hammersmith, the Carnations from Messrs. Hooper & Co., the Cyclamens and bouquets of Chrysanthemums from Mr. H. B. Smith, Ealing, and the wonderfully fine Chrysanthemum blooms from Mr. Harman, gardener to F. C. Capps, Esq., Crown Point, Ealing, also contributed much interest to the Show.

In the classes, all of which are confined to the district, the cut blooms were, as already remarked, extremely fine for so early a Show. Mr. J. Beesley, gardener to A. Fraser, Esq., Esthonia House, Ealing, had the best twelve incurved varieties. Capital samples of the following:—*Empress of India*, *Golden Empress*, *Queen of England*, *Lord Alcester*, *Lord Wolseley*, *Emily Dale*, *Mrs. Shipman*, *Prince Alfred*, *Mr. Buun*, *Refulgence*, *Jeanne d'Arc*, and *Baron Beust*. The finest stand of twelve Japanese came from Mr. H. Davis, gardener to H. G. Lake, Esq., Fairlawn House, Chiswick, who had splendid blooms of *Jeanne Delaux*, *Source d'Or*, *Margot*, *Thunberg*, *Mdlle. Lacroix*, *Comte de Germiny*, *Madame C. Audiguier*, *Hiver Fleuri*, *Madame B. Rendatler*, *Madame Louise*, and *Elaine*. Another successful competitor in these classes was Mr. Collyer, gardener to Mrs. Morrell, The Elms, Uxbridge Road, who also showed well in other classes, being first with six good Pompons. Mr. C. Long, gardener to E. B. Ridges, Esq., Orchard Dene, Montpelier Road, was first with nine fine incurved blooms, gaining the National Society's medal; the same exhibitor also had premier honours for six Japanese varieties, being good specimen blooms. Mr. C. Smith, gardener to Thomas Nye, Esq., Oakville, Castle Hill, took the lead with twelve bunches of Pompons, *M. Astie*, *Bob*, *Mdlle. Marthe*, and *Madame Montels* being remarkably fine. The best single bloom Japanese was *Madame C. Audiguier*, and the best incurved *Lord Alcester*, both from Mr. Beesley.

In the Grape class, Mr. Hudson, Gunnersbury House Gardens, was first with three capital bunches of *Muscat of Alexandria*, *Aluwick Seedling*, and *Alicante*, all well coloured. Mr. Hudson was also first with dessert and culinary Apples in a strong competition, his samples of *Golden Noble* being unusually fine. Messrs. Sutton's prizes for four dishes of Potatoes brought eleven competitors; Mr. John Farndon, 2, Vaughan Terrace, Southfields, securing the chief award, followed by Messrs. Wright, Dyer, and Chadwick. In the cooked Potato class *Reading Hero* was placed first and Schoolmaster second.

Certificates were awarded to Mr. Harman for Chrysanthemums *La Purété* and *Fabian de Mediana*; and to Messrs. Hooper & Co., Covent Garden, for *Carnation Chevalier*, a yellow ground variety streaked with red.

LAMBETH.—NOVEMBER 3RD AND 4TH.

In consequence of a considerable increase in the number of exhibits this amateur Society had last year to remove their Show to the Hawtstone Hall, Westminster Bridge Road, and in the same building this season's Exhibition was held. Though the competition was not quite so brisk in most of the classes as in the preceding year, yet the quality of the blooms and plants staged was fully equal to the best shows the Society has had in recent years. The competitors are residents within a radius of a mile and a half from the "Elephant and Castle," and the fact that the majority of the exhibits are grown under adverse circumstances and in the leisure time of the exhibitors—none being professional gardeners—renders their productions still more praiseworthy. The lateness of the season had, however, prevented several from exhibiting, but there was sufficient to give the hall a bright and cheerful appearance. An especial feature was the class for a group of Chrysanthemums to occupy a space of 80 square feet, and the four collections staged formed an important part of the general display, all being effectively arranged, and the first-prize group from Mr. H. Ellis comprised some well-grown plants bearing substantial blooms of good incurved and Japanese varieties. Messrs. J. Hole, W. Clark, and A. Ball followed in that class with bright groups. Mr. W. L. Tracey had some of the best-trained plants, and was first with six standards, six standard Pompons, and six Pompons, in capital condition and freely flowered. The standard Pompons were particularly good, the *Golden*, *Lilac*, *White*, and *Bronze Cedo Nullis*, with *Sanguineum*, being remarkably neat examples. Mr. T. F. Davison also was first with three standards similarly creditable.

The cut blooms were in several instances finer than we have seen them at this Show. Mr. C. J. Fill was very successful, securing the principal awards for twelve and six Japanese and six Japanese one variety (*Mons. Tarin*), the blooms in each stand being fresh and of good substance. The most notable were Mr. John Laing, *Roseum superbum*, *Japon Fleuri*, *Cry Kang*, *Le Chinois*, *Mons. Tarin*, and *Fernand Ferral*. Messrs. Child and Tracey followed in two of these classes. Mr. J. J. Hillier scored similar successes with twelve incurved, twelve Japanese, twelve large Anemones, and twelve Anemone Pompons. In another class for twelve incurved Mr. A. Ball was first, and Mr. W. Clark took a similar position for twelve large Anemones, Mr. H. Ellis leading with twelve bunches of Anemone Pompons, extremely fine, bright, and handsome. Reflexed varieties were also well represented by several growers. The awards included two silver cups, a silver teapot, a handsome album, and other useful and artistic prizes, which are more valued than money prizes would be. The arrangement of the exhibits, and the extremely neat accurate labelling is very creditable to the energetic Hon. Secretary, Mr. G. S. Addison, who has worked enthusiastically to improve the Society and its exhibitions.

BRIXTON.—NOVEMBER 4TH AND 5TH.

No more meritorious exhibitions have been seen at Brixton than the one briefly to be noticed as arranged under the experienced supervision of Mr. W. Hall, the Secretary. Though the date was early and the season late, most of the blooms were fully developed and the plants good. As the judging was only completed an hour or two before our going to press only a mere outline of the Show can be given, with the names of the chief prizetakers in the more important classes.

CUT BLOOMS.—The display of these was excellent, probably the best that has been provided at Brixton, and the competition extremely close. In the principal class of twenty-four incurved blooms, Mr. J. Holmes, gardener to G. M. Storey, Esq., Balham, secured the first position by a shave, Mr. J. C.

Salter, gardener to J. Southgate, Esq., being second. In judging the blooms, six points being taken as the standard, these two collections had an equal total, but the casting vote for freshness and evenness turned the scale. The finest bloom in these stands, and in the Show, was Mr. Salter's *Golden Empress*, 17 inches in circumference and nearly 5 inches high. Mr. Holmes had *Princess of Wales*, *Queen of England*, and John Salter in first rate condition, and the rest good. The third prize went to Mr. J. T. Salter, gardener to Mark Sheppard, Esq., Roupell Park. Mr. Holmes was also first in the class for twelve blooms, and Mr. Southgate a close second, with some larger but generally looser examples, this exhibitor being first in the class for six; Mr. Sadler, gardener to C. Lambert, Esq., second, and Mr. E. Cherry, gardener to Mrs. Gabriel, Streatham, third, the competition being good throughout. Mr. J. T. Salter took the lead with twelve large Anemones, very good; followed by Mr. Fulbrook, gardener to B. Baker, Esq., and Mr. Swain, gardener to E. Jones, Esq., Clapham Park. For twelve reflexed flowers, Messrs. J. Sadler; W. Howe, gardener to H. Tate, Esq.; and Mr. W. Livermore, gardener to F. Webb, Esq., were placed in the order named; the last-named exhibitors being alone in the class for twelve Anemone Pompons, staging beautiful examples. In the class for exhibitors of incurved blooms who had not previously won a prize, the honours fell to Messrs. W. Howe, H. Guyett, and A. W. Moorcock, for creditable stands.

Japanese varieties were splendidly staged, the chief winner in the class for twenty-four blooms being Mr. Pell, gardener to A. Margetson, Esq., followed closely by Messrs. C. J. Salter and T. Mursell, gardener to Mrs. Burton. The varieties cannot be enumerated, but one in the stand of Mr. J. T. Salter should not pass unnoticed. It has been certificated under the name of *Thomas Todman*, and was raised by Mr. Mahood. It has twisting thread-like florets of an "old gold" colour, distinct and bright. The prizes for twelve Japanese fell respectively to Messrs. T. Sadler, T. Mursell, and W. Howe.

PLANTS.—Mr. E. Cherry was first in the classes both for six and three plants with admirably finished examples with fine blooms, followed by Mr. W. Clarke. The best dwarf Pompons were staged by Mr. Weston, 3 feet across, and Mr. Cherry, who also had the best pyramids, followed by Mr. Livermore. The best standards were shown by Mr. Clarke.

AUTUMN SHOWS.

EXHIBITORS of Chrysanthemums will soon be actively engaged in preparing for the numerous shows announced for the present season, and the following list of fixtures may be useful as a reminder. Secretaries of Societies not mentioned will oblige by forwarding their schedules.

November	5th and 6th.—Richmond, Havant, and Highgate.
"	9th and 10th.—Stoke Newington.
"	10th.—Southend and Putney.
"	10th and 11th.—Brighton and Kingston.
"	11th.—Basingstoke.
"	11th and 12th.—National Chrysanthemum Society and Croydon.
"	12th and 13th.—Lindfield and Portsmouth.
"	13th and 14th.—Huddersfield.
"	14th.—Ramsbottom.

BANKSIAN ROSES.

THIS valuable class of climbing Roses is not so much grown as their merits deserve. They are most free blooming when rightly treated as regards pruning and situation or aspect, which are the principal considerations on which success in blooming them depends. They are usually regarded as shy bloomers, and so they are when pruned as ordinary Roses and placed in a situation where the exposure is not good enough. They will only succeed well out of doors in mild localities, where they may enjoy the fullest amount of sunlight. A full south aspect is the best; but in very warm localities they will do very well on a wall having a south-west aspect; south-east is less favourable. A light warm soil well drained is the most favourable to them. In a heavy soil, except they be protected by glass during autumn and winter, they ripen so badly that they often are injured; and even if they escape that they rarely flower well owing to the over-gross condition of their young growth. In localities in which they may not be grown successfully in the open air they must be accommodated with a position in a cool greenhouse or conservatory. They are quite worthy of such a position in any locality. They bloom so early that they are apt to be spoiled by the weather when they are fully exposed to it without any protection in localities where the spring climate is unfavourable.

There are four forms of Banksian Roses in cultivation. The oldest and best known is the white Banksian, which was introduced about eighty years ago from China. The flowers are small, very double, produced in large clusters, deliciously fragrant, with a considerable smack of the odour of the Sweet Violet. The yellow Banksian was introduced about twenty years later, and is similar to the white variety in every respect, except the colour of the flowers. Besides these there are the "Jaune Serin," with large, very bright yellow flowers, and the "Jaune Vif," also yellow, but somewhat smaller than the last named, which have originated in French gardens since the introduction of the species, and are well worthy of culture where there is room for them, as they are valuable climbing Roses. Then there is "Fortuniana," a form with large white flowers and peculiarly sweet, introduced from China about thirty-five years ago.

These Roses are usually reared in pots in nurseries for sale, and may consequently be planted out at any season of the year, but the best time is spring. The plants then have time to establish themselves before winter, and are, as it were, acclimatised before cold weather sets in. But if they are to be planted under glass it may be done at any time from January to December, according to convenience. As before said, a light warm soil is best for them, but the principal consideration is the drainage, which should be thorough, and the more so the heavier the soil is. The plants

will require no pruning except what is requisite to put them in proper form, and conduce to the filling of the space allotted to them as quickly as possible. The tendency to shoot away with strong vigorous shoots from the tops of the current season's growth, which they all have, must be restrained by cutting back such shoots; otherwise they will rob those at the base of the plant and leave it bare. When they have filled their allotted space the strong shoots must all be cut back annually, the weaker only being left, for it is on these that the flowers are produced. If the plants are very vigorous, and the crop of young shoots very numerous, it may be necessary to thin out the very weakest and the worst ripened, but this is rarely necessary, as when the plants begin flowering they lose some of their excessive vigour and produce a lesser quantity of young growth.

These Roses bloom in May or June, according to the locality in which they are grown, and they bloom on the shoots formed the previous season. They must, therefore, not be pruned till after their flowering season is over; but as soon as that is over no time is to be lost in dealing with them. The best way to prune them after they have filled the space allotted to them is to first tie in a moderate number of young shoots, so as to regularly furnish each tree at all points with the same character of branches, and then take the hedge shears and trim the remainder hard in. The main point is to note the period at which this should be done. Many that we have known attempt the culture of these Roses have pruned them as they would any of the summer-flowering Roses, thus pruning away the flowering shoots, and have condemned them as shy bloomers. If the pruning is deferred till after the flowering is over, and if all the other conditions are what they should be, there will be no cause to complain of the shyness of these Roses, but good grounds to marvel at their profusion. It will, however, be found necessary perhaps twice or thrice during the summer to look over the plants and cut back the gross shoots which may make way and threaten to impoverish the weaker-flowering shoots of next year; they should be cut back as soon as their character is determinable which will be easily done when they have attained a length of about 2 feet. It will then be seen whether they are to stop or run on; if the latter, cut them back.—(*North British Agriculturist*.)

HARDY FRUIT GARDEN.

THE lists of fruit given last month were selected with care, and a large proportion of the sorts enumerated will be found to answer in most gardens. But a real lover of fruit requires something more than a bare list; he wants ideas of which are the very best, such as he may regard as indispensable, and with which he may form the nucleus of an ever-increasing selection. He certainly has our warmest sympathy, and gladly will we help him. A Moorpark Apricot, a Brown Turkey Fig, an Orleans Plum, a Jargonelle Pear, a Ribston Pippin Apple, a Mayduke Cherry, a Grosse Mignonne Peach, a Pitmaston Orange Nectarine, a Warrington Gooseberry, and Keen's Seedling Strawberry. What garden can be without all of them? They are well-tried favourites of sterling merit, and the very mention of them brings to mind many a famous old fruit garden—aye, and many a favourite tree too. Let us make some additions to them. Of Apricots Kaisha and Orange, both excellent early varieties, affording a bountiful supply of fruit for preserving as Apricot marmalade. No doubt Brown Turkey is the most hardy and prolific Fig we have, but for a few dishes of really fine fruit we must plant a tree or two of Brunswick, taking especial care to afford them a warm sheltered corner of a wall or building facing south-west. Green Gage Plum is, of course, indispensable; so, too, are Purple Gage, McLaughlin's Gage, Transparent Gage, Bryanston Gage, Reine Claude de Bavay, Coe's Golden Drop, and Blue Impératrice. Of Pears we may name a few which prove good in most gardens, but it must not be forgotten what an uncertain fruit this is, none being more susceptible of the influence of soil and climate; and although the Pear Congress will doubtless do much good, yet we can hardly venture to consider its decisions as final, for many Pears are fruits of a season, being quite delicious one year and only suitable for stewing in another. Even Jargonelle must be watched closely, as the fruit becomes over-ripe and spoils so quickly. Williams' Bon Chrétien is certainly a safe sort to plant, and we may recommend that king of autumn Pears, Fandante d'Automne, with Comte de Lamy, Fondante de Charneau, Doyenné du Comice, Knight's Monarch, Seckle, Dana's Hovey, Jewess, Winter Nelis, Huyshe's Victoria, and Glou Morceau, as being a few of our very best Pears. But if you only have space for some single cordons, plant as many as you can 18 inches apart, and try the sorts we name and as many more as you can find space for. Nothing in fruit culture is more interesting than a collection of cordon Pears. Apples may be said to be badly represented by Ribston Pippin, because of the tendency of the tree to fail from canker. Well, by all means plant Cox's Orange Pippin; we have had a rich reward for planting it extensively, but we have also a few trees of Ribston Pippin, and of other really choice dessert sorts we have Kerry Pippin (so valuable in September), the high-coloured Worcester Pearman, King of the Pippins, Margil (so valuable for the freedom with which fruit is produced upon small trees), Pine Golden Pippin, Pine

Apple Russet, Golden Russet, Cornish Gilliflower, Reinette Van Mons. Melon Apple, Fearn's Pippin, Red Astrachan, and Hubbard's Pearmain. There are two Cherries which we consider indispensable for cooking and preserving—Belle Magnifique and Morello, and for dessert in addition to Mayduke space should be found for Governor Wood, Bigarreau, and Black Tartarian. Of Peaches Early Beatrice is 20 per cent. better against an open wall than when grown under glass, the fruit being of higher colour, and it is really rich in flavour. It is so much in demand that there should at least be two trees of it. Barrington and Walburton Admirable must also be had for our supply of late fruit, and for intermediate sorts Dr. Hogg, Rivers' Early York, and Belle Bauce. If, however, you can only afford space for one tree, let it by all means be a Grosse Mignonne. The best late Nectarine we have is Pine Apple, with richly flavoured yellow flesh quite equal to Pitmaston Orange. Downton and Balgowan are grands Nectarines, and Rivers' White affords some pretty dishes of fruit.

FRUIT FORCING.

VINES.—*Early-forced Vines in Pots.*—Where thin-skinned Grapes are required in April, they taking precedence of Lady Downe's and other late varieties, the house intended for their culture will now be ready for their reception, if indeed they are not already in position. The pots should be placed on stands or pedestals which will not give way under their weight or interfere with turning the fermenting materials used for supplying bottom heat, than which nothing answers better than bricks placed to the required height without mortar. Where weight and quality of crop are first considerations some turf should be packed against the pedestal, and the holes in the pots enlarged, bringing the turf up above these so as to be within easy reach of the roots, which will speedily follow the stimulating food with which the Vines are fed. For supplying bottom heat Oak leaves are the best, as they supply heat and moisture through the early stages of growth and rich stimulating food from their decay at the finish, when the fruit requires all the support that can be given to it. Care should be taken that the heat about the pots does not exceed 70° to 75°. The canes should be allowed to fall in a horizontal position over the fermenting material until they have broken, and be syringed two or more times a day, but sufficiently early for the last time each day to allow of the canes becoming fairly dry before nightfall. If the Vines have not been shortened to the proper length and dressed with styptic they must not be shortened now, as bleeding would weaken them, and it is easy to disbud when they start. Black Hamburg, Royal Ascot, White Frontignan, and Foster's Seedling are excellent kinds for early forcing in pots, to which may be added Madresfield Court, which requires liberal feeding until the berries show signs of changing colour, when a gradual diminution, combined with a dry atmosphere, is necessary to prevent cracking.

Earliest-forced Planted-out Vines.—The houses containing Vines from which ripe Grapes are expected early in May should be closed by the middle of this month, or if the Vines are young and vigorous and not subjected to early forcing before, close the house at once, as they do not break so quickly as old ones that have been forced for a number of years. With a view of economising fire heat, and to produce a humid atmosphere, a good bed or ridge of fermenting material, consisting of two parts leaves and one of stable litter, may be placed upon the border and turned over at short intervals, additions being made as the heat declines. In the cases of old rods they may be tied up to the wires as soon as they are dressed, but young canes ought to be suspended in a horizontal position over the fermenting materials, where they can be well syringed with tepid water slightly warmer than the house, but it is well to allow them to become dry at least once in the twenty-four hours or at night. Keep the temperature at 50° to 55° at night, and 65° on fine days, the temperature by artificial means in the day being 55° until the Vines begin to move. If the border is not in a thoroughly moist condition it must receive repeated supplies of tepid water or liquid manure if the Vines are weak, so as to thoroughly moisten it through.

Midsason Houses.—Those that still contain a few bunches of Black Hamburg and other thin-skinned Grapes may now be cleared, as the fruit will keep fresh in a cool dry room, and the Vines will derive great benefit from free exposure to the weather so long as it continues dry and mild. When thoroughly at rest Vines will not be injured by a little frost, but a sudden chill should be guarded against by drawing up the roof-lights, or closing the houses when the nights are likely to be wet and frosty. The Grapes should be cut with all the wood that can be spared for insertion into bottles of water, which should be soft, and a piece of charcoal placed in each, removing the old foliage, but do not shorten the wood that has been allowed to extend beyond the bunch.

Succession Houses.—Push on the pruning as soon as the Vines become clear of foliage, also the cleansing, painting, and lime-washing, carefully washing the Vines with soap and water prior to dressing with an approved insecticide. Presuming the Vines have been fairly free of insects, the old-fashioned practice of peeling, scraping, and painting with a pigment of clay, soot, sulphur, and other nastiness, which is more calculated to protect the larvæ than destroy it, is better to wash twice and preserve the beauty of the bark, which is of incalculable value in holding moisture from the syringe and aids the flow of the sap when they are starting in growth when excited by genial moisture and warmth.

Late Hamburgs.—The atmosphere in which bunches of these are hanging cannot be kept too dry. A steady temperature of 50°, with a little warmth in the pipes and liberal ventilation on dry days, will suit them during the fall of the leaf, when, unless the house is well adapted for keeping them, the bunches may be cut, bottled, and placed in the late houses.

Late Houses.—If late Grapes have not finished well, nothing will be gained by pushing the fires after the wood is ripe, neither will a high temperature prevent them from shrivelling when the leaves fall. Where this defect is the consequence of over-cropping, relief should be given the Vines by cutting a portion of the bunches at the earliest convenience; but where it can be traced to imperfect drainage or bad borders, no time should be lost in getting out the old soil and laying the roots in new compost over rectified drainage. Highly finished Muscats hanging on Vines that have lost their leaves are liable to be tinged by exposure to bright sunshine, which, though weak in November, disfigures them to some extent, especially when grown for market. To guard against this, which is only needed in case of houses with large panes of glass, a single thickness of pilchard nets drawn over the roof will be a sufficient shading. If not already done late Vine borders should have some covering placed over them that will throw off rain and snow. The inside borders will be getting dry at the surface, and should be covered with some dry fern or straw neatly spread over them, which will prevent the border cracking and its giving off dust, besides improving their appearance. Give daily attention to the removal of ripe foliage as it parts from the Vines, keeping cool, dry, clear of plants requiring water, and thoroughly clean.

PLANT HOUSES.

Lily of the Valley.—Plants that have been prepared in pots for early forcing as directed in spring have ripened their foliage and have been resting for some time. The two or three slight frosts that we have had lately have been beneficial for these, as they will start better and more quickly into growth when introduced into heat. This may be done without delay. Plunge the pots in cocoa-nut fibre refuse or sawdust some inches beneath the surface where a uniform bottom heat of 80° to 85° can be maintained. If the top heat can be kept at 65° to 70° it will be ample. When the plants have commenced growth they should be placed nearer the surface, so that the flower spikes and foliage can grow through and thus gradually expose themselves to light. The flowers and foliage of this lovely Lily are often crippled by lifting them from the plunging material and exposing them directly to full light. Plants that have been growing in the open ground on purpose for lifting may now be taken up and sorted. Reserve the best crowns for potting or placing in pans and boxes according to requirements. The smaller ones can be planted again on the same ground after manuring it well to be ready for lifting again in two years. Under this system it is necessary to make a plantation annually, and then a portion is ready for lifting every year.

Obtain imported clumps now and place them in 5 and 6-inch pots, arranging them outside until they have been exposed to sharp frost, when they may be placed in a cold frame. Single crowns (imported) are now largely used for early forcing, and should be placed in boxes and pans at once if the flowers are required early. These may be potted, but we usually lay them in leaf soil. The boxes must not be too large, for they come forward more evenly in small than large ones. If these are placed into heat directly they will not start freely into growth. Those stood outside for two or three weeks and sent to rest by frost will come into flower before those introduced as soon as imported.

Spiraea japonica.—These may now be lifted, selecting those only with large plump crowns that are certain to flower, and place them in 5 and 6-inch pots. The portions with small crowns can be laid in a heap with a little soil or ashes over them until a convenient time for planting. The plants reserved for this purpose should be cut into suitable sizes, so that they will go into the pots named after a season's growth. They should be planted on ground liberally enriched with manure and fully exposed to light and air, which is essential to the development of strong flowering crowns in one season. Moderate-sized crowns are much better for planting for next year than larger ones that may probably flower. The smaller ones develop into a flowering size, while those that flower naturally divide into a number of smaller and weaker crowns, requiring two years before they become of a flowering size. By planting the pieces with small crowns a stock of flowering plants are annually raised, and those that have been forced can, when they have done flowering, be conveyed to the rubbish heap.

Dielytra spectabilis.—These also must be lifted and potted as advised for Spiraeas. Small or weak crowns should be planted again for another year in rich soil. If sufficient stock cannot be obtained from these a few good-sized plants should always be kept on hand, to be lifted and divided for this purpose. Some of the plants that are forced are good for this purpose if planted out in the shrubbery and other borders for a year or two to thoroughly recruit themselves. All those forced can be planted out afterwards, if not they can go to the rubbish heap. Those planted for another year should have a sheltered position, where they will be protected from spring frosts, for they start early into growth and are very liable to suffer. The crowns should also be protected from severe frosts by scattering over them a little litter or half-decayed manure. These may be placed in a frame or any cool place after potting.

Solomon's Seal (*Convallaria polygonatum*).—Lift the largest crowns for potting in various sized pots according to requirements. These plants, with their arching stem of leaves and flowers, are very useful for ornamental arrangements in the conservatory or elsewhere. The small crowns should be planted for lifting next autumn, the same as advised for Spiraeas and Dielytras.

Lilium longiflorum and Harrisi.—Obtain bulbs of these and pot them at once if they are wanted in flower early in the season. Place single bulbs in 4-inch pots in a compost of loam three parts, the other part being composed of leaf mould and manure; to this may be added

a good dash of coarse sand. Cover the bulbs with soil when potting them. After potting stand them in a cold frame and cover with about 1 inch of cocoa-nut fibre refuse. They can remain in this condition until they grow through the plunging material. When wanted early place the pots containing the bulbs where a greenhouse temperature can be maintained, but cover in the same way.

Other Plants for Forcing.—Azalea pontica, with the Ghent and Mollis varieties as well as Hybrid Rhododendrons, should now be lifted for forcing. Pot them in good loam, and afterwards they need not be taken indoors, but can be plunged outside until they are wanted. As fruit houses are cleaned these are placed in them in batches ready for starting with the various houses, to be eventually drafted from the forcing house. The steady heat of these structures start the plants slowly, and they come forward rapidly when introduced into the closer and warmer atmosphere of the forcing house.

THE FLOWER GARDEN AND PLEASURE GROUND.

Tuberous-rooted Plants.—In some positions Dahlias and various other tender bedding plants are still flowering freely, and in this case it is not necessary to interfere with them, but where they have been rendered unsightly by the frosts they may well be lifted and stored. Dahlias to have their stems cut down to about 9 inches of the roots, and after they have been lifted or dried, the stems being downward while this is being accomplished, to be stored in a cool dry outhouse, potting shed, or cellar. The labels bearing either the name or description of each variety to be securely fastened to each, this preventing much confusion at propagating time. Now that there are such a great variety of singles it is unwise to preserve any but the very best sorts. Cannas to be lifted and treated similarly to the Dahlias, with the exception that the soil should not be so freely cleared from the roots. Salvia patens when lifted to be stored thickly in a box of fairly moist soil, and these may be wintered with the Dahlias. Verbena venosa forms long fleshy roots, and as many of these as possible should be lifted and packed thickly in boxes of good soil and wintered in a cold frame, house, or pit. It is by means of short lengths of these fleshy roots that the stock can be most readily increased next spring. Tuberous-rooted Begonias are now largely planted in the flower garden, and they fully deserve to become even more popular. Those that are damaged by frosts may now be lifted and stored thickly in boxes of slightly moist soil, and this will preserve them in a plump state during the winter and early spring months. This less fire heat this class of plants receive after they have formed good tubers the better. They should be wintered in a dry frame, pit, outhouse, or in a greenhouse, where no drip will reach them. These and all the foregoing will require to be carefully protected from severe frosts, but must not be coddled, or otherwise they are apt to start into growth prematurely, and be considerably weakened thereby.

Spring-flowering Plants.—Many of these are much smaller than usual, this being especially the case where the seed was sown rather late, and unless they are planted more thickly than heretofore the ultimate effect will be weakened. Transplanting at this time of year should be done as much as possible during dry weather, as this admits of its being done cleanly and well. It is of great importance that each plant be lifted with good balls of soil and roots, and be firmly fixed when replanted. They will also require to be firmed after severe frosts, as these loosen them considerably and greatly interfere with the free rooting and flowering habits of the plants. All are great exhausters of the ground, and as they make but poor progress on poor soil it may be advisable in some cases to dig in a quantity of decayed manure or leaf soil. Mixed borders especially usually stand in most need of manure, and unless it is given either now or in the spring without stint the occupants cannot reasonably be expected to grow healthily. All the various kinds of bulbs that require to be planted at the present time will produce finer spikes and heads of blooms when the ground is properly manured and otherwise well prepared for their reception. For this class of spring-flowering plants or bulbs well-decayed manure should be used, this being well mixed with the soil in preference to merely turning it in to a great depth. The Narcissus, Daffodils, Snowdrops, and Tulips ought always to be planted early, the two former especially so, while Hyacinths may be planted now or a month later, according as to whether an early or late display is required. All are most effective when grouped or planted in lines of one colour in preference to haphazard mixtures. The bulbs should be disposed about 2 inches below the surface, and choice sorts may well be surrounded with good gritty compost.

Selections of Roses.—The time has arrived for ordering and planting Roses, or they may be purchased and carefully laid in where they can be protected during severe frosts, planting being deferred till the spring. Roses planted at the present time freely form a few fresh roots before the winter, and break more strongly in the spring in consequence; but then they are not so easily protected during severe weather, and those laid-in Roses start surprisingly well after they are planted, providing the delicate young fibres they form to a surprising extent are not injured during the act of transplanting them. If the Roses, whether dwarfs or standards, are received in bundles, these must be separated and laid in thinly, and not in heaps as we have seen them. We may again escape very severe frosts, but it is always best to prepare for them. Rough straw litter thrown over those laid in will save them, and a heavy mulching of the same material will also benefit those planted out. Land that has long been occupied with Roses is scarcely suitable for new plantations, but if this cannot be avoided it should be trenched, unless the subsoil prevents this, and some good fresh compost should be placed about the roots. The following Hybrid Perpetuals are worthy of culture:

in most districts, and succeed either on tall or dwarf stocks:—Alfred Colomb, Bessie Johnson, Camille Bernardin, Captain Christy, Comtesse d'Oxford, Duke of Edinburgh, Dupuy Jamain, Edouard Morren, Etienne Levet, François Michelin, Général Jacqueminot, Horace Vernet, John Hopper, Jules Margottin, La France, Lord Clyde, Louis Van Houtte, Madame Charles Crapelet, Madame Clemence Joigneaux, Madame la Baronne de Rothschild, Madame Victor Verdier, Mdlle. Marie Rady, Marguerite de St. Amand, Marie Baumann, Madame Gabriel Luizet, Princess Mary of Cambridge, Madame Prosper Laugier, Marquise de Castellane, Maurice Bernardin, Sénateur Vaisse, Star of Waltham, and Victor Verdier. Tea-scented and Noisette Roses as a rule are best grown on dwarf stocks, but in mild districts they may last for several years on tall Briar. The following are good:—Catherine Mermet, Souvenir d'un Ami, Devoniensis, Maréchal Niel, Madame Lambard, Madame Bravy, Souvenir de Paul Neyron, Celine Forestier, Adam, Madame Berard, Madame Falcot, Amazone, Sunset, Gloire de Dijon, Caroline Kuster, Anna Ollivier, Madame Hippolyte Jamain, Perle des Jardins, Rubens, Jean Ducher, Grace Darling, Comtesse de Nadaillac, Marie Van Houtte, Souvenir d'Elise, and Etoile de Lyon. The following Bourbon Roses are also worthy of culture:—Acidalie, Bouquet de Flore, Comtesse de Barbantanne, Souvenir de la Malmaison, Sir J. Paxton, Baron Gonella, and Malmaison Rouge.

THE BEE-KEEPER.

NOTES ON BEES.

SMOKER.

"BASIL" appears to have a difficulty in keeping his smoker alight, "going out when it is set down." To avert this, keep it on end, and be careful that it does not get clogged up. Cleaning its internal parts frequently is necessary, so that it may work satisfactorily—but the less smoke the better for bees and honey.

GLASS IN SUPERS.

I never was favourable to glass in supers or hives to any extent, and I have still a growing dislike to its employment, particularly in hives. Wherever glass is employed in supers, it is there the bees are longest in sealing, often so tardy that the super is discoloured before it is sealed opposite the glass. So I prefer either very small panes, as is in the Stewarton hive, which serve as good indicators when the super is finished; or none at all, then a slight tapping with the finger over the super will indicate to the experienced bee-keeper, by the sound, whether it is filled or not. Or looking between the bars from the top gives some knowledge. Many bee-keepers have holes in their supers stopped with corks, which answers the purpose well.

THE TEMPERATURE OF OCTOBER.

With the exception of snatches of bright sunshine, October has, like its two predecessors, been very low, three and four nights in succession registering 9° and 10° of frost, and on one 14°; in fact, there were few nights but what frost was registered. I do not know whether this early and wintry weather augurs a mild or severe winter later, but past experience proves that, as a rule, there are seldom two winters, and that when one occurs in October there is no winter after. Be that as it may, the past month has been trying enough and puzzled bee-keepers much how to get their driven bees fed for the winter, this having been delayed a month beyond the usual time in consequence of the lateness of the Heather. A number of bee-keepers who were there found a difficulty in getting their bees to feed at all after having tried different top feeders, including the bottle. In the absence of the frame feeders I advised the common tin fountain for under feeding; in every case the bees took to it at once, thus negating the opinion of some that top-feeding is the surest and most natural. Much could be said on this subject, but it is needless to dwell on it; the bees themselves give the best lessons, and, no matter what may be said to the contrary, they give ample proof that they prefer the frame feeder or the fountain underneath to all others, at a time when we ought to know it is not only too late but too cold to feed in October. Hundreds of hives have been ruined by late feeding, following the advice

given in the *British Bee Journal* to feed in October for years in succession.

It is one of the most amusing things in the world to read bee literature, including trade catalogues. In the one nearly all the inventions for apiculture is concentrated to one individual, while in the other contradictory remarks provoke and perplex the reader. I know that many so-called inventions of the present day were in use long ago; that much that is written on that and kindred subjects have other purposes to serve than instructing bee-keepers who are supposed to be less well informed than themselves, but who may be in reality far behind. I need not say more on this at present, but I trust the hint will not be lost. We are all desirous of information, but it can only be rightly appreciated when given in a straightforward and uninterested manner. Appropriating others'

FIG. 63.

ideas is as mean as it is contemptible. I may yet have a battle to fight to rectify some of these mistakes, as I had in the "battle of the hives," which is now decided I am on the winning side.

Notwithstanding the opinions of the different systems of apiculture, it must be ceded, generally speaking, that since bees were cultivated it has been the aim of bee-keepers throughout the world to obtain honeycomb pure and uncontaminated from brood or other concomitants of the hive. The Stewarton hive is perfect in this respect in all its simplicity; yet, notwithstanding this, I confess many modern hives are as far from this as are the poles asunder. This brings me now to a point of importance, and on which I am backed up with proof positive that I am right in my argument, by the very individuals I hint at having so much to say against their neighbour manufacturers' hives in being so badly fitted for bee receptacles and for honey-producing.

One of the contrivances for obtaining honey in white comb is the "reversible frame." New in the mode of application, but not in principle; commendable in certain cases, but a system which should not be encouraged generally, because, as your excellent correspondent "Felix" would say, can be accomplished an easier way. The woodcut shows a plan which appeared about a quarter of a century since in a Dumfries paper, and, although the text is wanting, my conclusions are that it is a plan for obtaining white comb by inverting the full hive underneath an empty one to be filled, and as the Dumfries bee-keepers only began to leave off their primitive styles of bee-keeping after the first visit of the Caledonian Apiarian Society to Dumfries in 1879, and as the plan has been tried in other places confirms my opinion.

But, should this meet the eye of anyone who has seen the article referred to, the information will, I am sure, interest more than—A LANARKSHIRE BEE-KEEPER.

TRADE CATALOGUES RECEIVED.

John Carter, Hollycroft and Willow Bank Nurseries, Keighley.—*Catalogue of Forest, Fruit, and Ornamental Trees and Shrubs.*

Charles Van Geert, Antwerp.—*Select List of Ornamental Trees and Shrubs.*

T. Laxton, Bedford.—*Lists of Novelties.*

* * All correspondence should be directed either to "THE EDITOR" or to "THE PUBLISHER." Letters addressed to Dr. Hogg or members of the staff often remain unopened unavoidably. We request that no one will write privately to any of our correspondents, as doing so subjects them to unjustifiable trouble and expense.

Correspondents should not mix up on the same sheet questions relating to Gardening and those on Bee subjects, and should never send more than two or three questions at once. All articles intended for insertion should be written on one side of the paper only. We cannot reply to questions through the post, and we do not undertake to return rejected communications.

Dessert Apples (F. J.).—We know of no Apple bearing the name of Phoebe, it must either be a local variety or there has been some mistake in labelling.

Garden Labels (W. K.).—Your notes, or at least those written on one side of the paper, were published on page 380 last week. We are obliged by your supplementary letter, which is too late for insertion this week.

The Silver Tree (W. A.).—The plant of which you sent a leaf is a member of the natural order Proteaceae, and is known to botanists as *Leucadendron argenteum*. It is a native of the Cape of Good Hope, where it is known to the Dutch colonists as Witteboom, or Silver Tree, a name which it owes to the silvery appearance of the leaves. The plant is in cultivation, and may be seen at Kew and in a few other establishments where large collections of old and curious plants are grown. It was introduced towards the close of the seventeenth century, so that it is by no means a novelty. Leaves are imported for decorative purposes with the Cape Everlasting Flowers, and may be frequently seen in Covent Garden Market. A figure of the plant was published in the "Botanical Register" in 1826, but it does not show the peculiar whiteness of the foliage.

Tenant's Greenhouse (A. D.).—If you do not embed the bricks in mortar nor rest the sill in mortar on them, nor secure any part of the house to the landlord's building with nails, your house will be a tenant's fixture, and you can remove it and the bricks at any time. We do not know whether any Building Acts apply in your district. Where these are in operation a rather heavy fine can be imposed on anyone who erects a greenhouse without giving notice to the surveyor, whose duty it is to sanction the plans, and he can claim a fee for his usually unwelcome "assistance." Our small manual on greenhouse plants is reprinting.

Exhibiting Chrysanthemums (E. T.).—Annie Salter, Alma, Christine, and King of Crimson are reflexed varieties, the blooms opening out more or less flat, and the florets turning back rather than otherwise. If you exhibit such varieties in the class you mention you will be disqualified, or ought to be. Incurved flowers are those in which the florets turn upwards and meet in the centre of the bloom, curving inwards like the fingers of your half-closed hand. Those alone are eligible for staging with Japanese blooms in the class indicated. The name of the shrub of which you have sent a spray is *Cotonaster microphylla*.

Chrysanthemums for Grouping (Hall).—Everything depends on the wording of the schedule in respect of the class in which you desire to exhibit. We have many times seen Chrysanthemums effectively associated with stove and greenhouse plants in groups arranged for effect at autumn shows; in fact, such mixed groups are invited in the schedules of some shows, while in others Chrysanthemums are excluded. The arrangement of the plants is purely a question of taste on the part of the exhibitor. The ground is marked out, and competitors have to occupy the space the most effectively.

Table Plants for Exhibition (Idem).—A great deal more depends on the freshness and condition of plants than on any particular kinds for securing prizes. *Cocos Weddelliana*, *Geonoma gracilis*, *Aralia Veitchii*, *A. elegantissima*, *Reidia glaucescens*, *Croton interruptus aureus*, and slender-leaved *Dracaenas* are suitable for the purpose in question.

Eriobotrya japonica (Medicus).—This, commonly called the Loquat, grows very well planted out and trained to south walls in the south of England, but except in very favourable situations needs the protection of glass. We figured fruit of it in 1881 grown in Lady Parker's conservatory at Richmond, Surrey. The tree was then 9 or 10 feet high, in a pot about

14 inches in diameter, and it bore a dozen bunches of eight or ten fruits each at the ends of the branches, where the long rich dark green leaves were clustered as they usually are in specimens of moderate size. The tree had been previously in a stove, where it flowered late in the autumn, and having received careful attention a crop of fruits was set which gradually advanced to about the size of Apricots, and became fully ripe towards the end of March, then assuming a fine orange tint. They were not only larger than many we have seen, but possessed a much richer flavour than any we have previously tasted. As they each contained a single seed, it is probable the variety is that referred to by Fortune as the one most highly valued by the natives of China and Japan. There is a great difference in the quality of the varieties, some being comparatively worthless; and wherever this or any other foreign fruit is intended to be grown, a point of great importance which is frequently overlooked is the selection of the variety. The great defect in most of the fruits of the Loquat which are occasionally seen in the metropolitan markets is their insipidity or even unpleasant flavour, due probably to their having been gathered in an unripe condition. The first record we have of a tree producing fruits in England occurs in the third volume of the Horticultural Society's Transactions, published in 1822. A letter is there printed from Lord Bagot of Blythfield, Staffordshire, which was read before the Society in 1819, and recounts the fruiting of a tree in one of his lordship's houses. Fruits were produced during several years, generally of very fine quality and extremely numerous, as many as twenty-one having been borne on one branch. The method adopted was to place the trees out of doors during the summer, removing them to a warm tan bed in September. The flowers generally expanded in December, and the fruit was ripe by April. But on one exceptional occasion the flowers appeared in early summer. From that time until the present there have been few records of the production of fruit under glass. Loudon mentions one or two instances, and others have been noticed at wide intervals, but it is still an event of considerable interest. There are scarcely any well-authenticated instances of trees maturing fruit out of doors in England, though in the south of France, Malta, and neighbouring regions it is produced in great freedom.

Judging Chrysanthemums (A New Censor).—Generally speaking as was once suggested by Mr. Bardney, the rules published in the "Rosarians' Year Book" for the guidance of judges may be taken as the foundation for judging Chrysanthemums. **Definition of Blooms.**—1, A good Chrysanthemum must have form, size, brightness, substance, and be at the time of judging in the most perfect phase of its possible beauty. 2, A Bad Chrysanthemum.—All blooms shall be considered bad that have faulty shape, confusion of petals, removal of lower petals, faded colour, and which are oversized to the extent of coarseness, or undersized so as to render them puny, according to the character of each variety. 3, Form shall imply petals abundant and of good substance, regularly and gracefully disposed within a circular symmetrical outline. 4, Brightness shall include freshness of colour, brilliancy, and purity. **Judging.**—1, Judging shall be by points. Three points shall be given for the best blooms, two for mediums, one for those not so good but not bad enough to cut out, and an extra point for a very superior bloom. 2, One point shall be taken off from the box for every case of decided badness. 3, Where stands are equal in respect of blooms judges shall proceed to consider the general evenness, variety, arrangement, and setting up, the boxes being placed side by side and in the same light for that purpose. Those rules form a good base, but Chrysanthemum judges must be familiar with the standard character of the several varieties, and estimate their merits accordingly—that is to say, a bloom of Cherub, for instance, may deserve as many points as one of Empress of India, or more, if the former, though larger, be not good of its kind, while the latter, though decidedly smaller, is first-rate. They have to take into consideration size with symmetry and solidity, length and breadth of petal, also freshness and colour. The mere circumference of a flower is in itself not at all a reliable test, as loose flat examples may girth much more than others of twice their depth and firmness, yet these latter would be the more meritorious. We consider that six points should be the standard for a perfect bloom, one in which a fault cannot be found, as the slightly differing gradations in merit can scarcely be expressed when only three points are allowed as a maximum. We hope you have an experienced judge as a colleague.

Spiraea japonica in Pots (S. P. F.).—The following is the practice of a first-rate grower of these plants:—Pot the clumps as soon as they are received into 5 and 6 inch pots, according to the size of the roots. One large crock may be placed at the base of the pots, but for those required for late flowering this is not important. They do not need very much soil to grow them to perfection, provided the crowns are strong and have been well ripened, for upon this depends whether they flower well or badly. Any good fertile soil will do for them; but we prefer, where obtainable, good fibry loam, to which has been added one-seventh of decayed manure. In potting leave plenty of room for water, for an abundant supply will be needed when the plants are in active growth. After potting you may stand the pots outside until the approach of severe weather, when they will need the protection of a cold house or frame. This is not really necessary with those required for late or spring flowering, for they will be safe if the pots are plunged in coal ashes and the surface covered about 2 inches deep, so as to protect the pots from the action of the weather. *Spiraeas* are perfectly hardy, so that a very little protection to preserve the pots will keep the crowns in perfect condition. With the exception of a few required very late we prefer giving them protection under glass, for they start naturally into growth early in the spring, and thus render the work of forcing comparatively easy. These plants are easily forced into bloom in a temperature of 60° to 65°, which will be necessary early in the season; later a lower temperature will suffice. It is a good plan to bring them forward after the first batch or two under slightly cooler conditions, so that they will not become drawn up weakly. After the plants have started into growth they should be given a circulation of air daily when favourable. When growth has fairly commenced the plants should be arranged as close to the glass as possible to keep them dwarf and sturdy. Before they come into full flower gradually inure them to cooler treatment to harden both the flowers and foliage, by which means they will be preserved in good condition for nearly double the length of time than if fully developed in strong heat. If wanted

very early in flower plunge in brisk bottom heat and cover the crowns with an inch of cocoa-nut fibre or any other similar material until they start freely, when they may be grown without bottom heat. Plants started early—say at the present time—cannot be expected to do so well as those that are started later and brought forward under more natural conditions. *Spiræas* should never be dry at their roots, and when they have once developed a quantity of foliage and are showing their flowers stimulants in a weak state may be given freely. They must be kept free from insects by syringing, fumigation being injurious. When in full growth it is scarcely possible to give them too much water.

Names of Fruits.—The names and addresses of senders of fruit to be named must in all cases be enclosed with the specimens, whether letters referring to the fruit are sent by post or not. The names are not necessarily required for publication, initials sufficing for that. (*J. P.*).—The Peach is undoubtedly Salwey. (*R. H. R.*).—1, Baron Ward; 2, French Codlin; 3, Dumelow's Seedling. (*J. H. Neale*).—1, London Pippin; 2, Ribston Pippin; 3, Golden Noble; 4, Bedfordshire Foundling. (*A. S.*).—Apples—1, Greenup's Pippin; 3, Cellini; 5, Golden Winter Pearmain. Pears—1, Winter Nelis; 2, Summer Bergamot; 3, Marie Louise. (*F. T. Drummond*).—Apple—Winter Colman. Pears—1, Suzette de Bavay; 2, Passe Colmar; 3, Beurré Diel; 4, Ne Plus Meuris. (*A. Wilson*).—7, Beauty of Kent; 8, Minchall Crab; 9, Ord's Apple; 10, Pomeroy; 11, London Pippin; 12, Yorkshire Greening. (*G. M.*).—Grosse Calebasse. (*J. Jefferies and Son*).—5, Nonesuch; 6, Probably Golden Noble, very small; 7, Norfolk Colman; 8, Gloucestershire Costard. (*W. E.*).—1, Ribston Pippin; 2, Cox's Pomona; 3, Kentish Fillbasket; 4, Syke House Russet; 5, Beurré Hardy; 6, Passe Colmar. (*J. E. F.*).—1, Royal Russet; 2, Yellow Ingestrie; 3, Glou Morceau; 4, Beurré Diel; 5, Urbaniste; 6, Comte de Lamy. (*G. B.*).—13, Beurré Diel; 14, Marie Louise; 15, Beurré Rance; 16, Swan's Egg; 17, Josephine de Malines; 18, Beurré Superfin. (*H. Rowley*).—1, Hawthornden; 2, Winter Greening; 3, Cockle's Pippin; 6, Minchall Crab; 7, Dumelow's Seedling; 10, Golden Reinette. We only undertake to name six. (*A. D. Preston*).—1, Hollandbury; 2, Catshead; 4, Holland Pippin; 5, Bess Pool.

Names of Plants.—We only undertake to name species of plants, not varieties that have originated from seed and termed florists' flowers. Flowering specimens are necessary of flowering plants, and Fern fronds should bear spores. Specimens should arrive in a fresh state in firm boxes. Slightly damp moss or soft green leaves form the best packing, dry cotton wool the worst. Not more than six specimens can be named at once. (*G. M.*).—1, *Dendrobium chrysotoxum*; 2, *Zygopetalum intermedium*. (*W. R.*).—The large Aster is *Aster puniceus*, the small one *Aster Novibelgii* var. *laevigatus*; the *Fuchsia* is *F. conica*; the others we do not recognise. (*T. M. E.*).—The flat leaf-like plant is *Coccoloba platyclada*, the other is *Cacalia articulata*. (*T. Baigent*).—The slips sent are not in condition for anyone to name with accuracy, and all we can say is—No. 1 is a *Chorozema*; 2 and 3, unrecognisable; 4, an *Acacia*; 5, a *Statice*; 6, an *Epacris*. (*John Cameron*).—1, *Cupressus virginiana*; 2, *Cupressus torulosa*; 3, *Tanja occidentalis*; 4, *Cedrus Libani*; 5, *Quercus Ilex*; 6, *Eriobotrya japonica*. You will find the information you require in our reply to "Medicus."

COVENT GARDEN MARKET.—NOVEMBER 4TH.

sustained, and that the cream may be abundant and rich, and the butter of a delicate flavour. No doubt cows of a particular breed exercise much influence in these matters, but the milk of every cow will be spoilt—at any rate for butter-making, if an impure, unwholesome diet is suffered to taint the milk, as it does invariably. A system of chaffing and mixed food is good for them, but the racks should be kept well supplied with the best meadow hay three times daily, and not twice only—morning and night, as is so frequently done. Long fasting is bad for all animals, and we have repeatedly seen cows that were fed only twice daily eating litter saturated with filth, which must affect the flavour or both milk and butter.

It must not be forgotten that dairy cows upon the home farm are not kept solely for milk, as are the cows of many tenant farmers, and therefore the winter diet, of which pulped Turnips, brewers' grains, Swedes, and Oat straw form the chief ingredients, will not answer for them, such a dietary being intended solely for the promotion of a full yield of milk, little if any attention being given to quality. In the home farm herd quality must be kept well to the fore; we must have rich cream and butter of high colour and delicate flavour. To this important end the careful selection or breeding of cows must be combined with judicious feeding. The best meadow hay is the chief article of winter diet to be used both for chaffing and unchaffed in the racks. Use no inferior hay in any manner for them, and do not allow dealers in cattle spice to induce you to suppose that musty hay can be made equal to really good hay by a dressing of the spice which they are so eager to sell. No doubt the spice makes inferior food palatable, but it cannot make it proportionately nourishing. Bran is always given to the cows at milking time. They eat it greedily and derive much benefit from it. Long ago we tried to do without bran, but the deterioration both in quantity and quality of the milk was so great that we quickly resumed the regular use of it. Bran is not used while there is a full bite of grass, but is given early in autumn, and its use is continued until the cows are turned out upon the pastures in spring. Our readers must not forget how frequently we have asked them not to turn out the cows in winter, and not to do so in spring till the grass is strong upon the pastures, and is growing so freely as to insure them of food for rumination in from one to two hours after milking. We never turn them out in winter or spring till mild weather insures a continuance of growth, and the full allowance of dry food is given till then. With the bran we are now giving sliced Carrots at the time of milking, or twice daily. The quantity of bran is from one to two gallons, and the same of Carrots to each cow, according to size and condition, which also affects the use of chaff. For example, to a delicate Jersey a full allowance of bran, Carrots, and a few crushed Oats may be given, while to a big shorthorn or crossbred cow a mixture of bran, Carrots, and chaff will suffice. It is well to be particular about having the Oats crushed and seeing that a given quantity only is used. One of the best cowmen we ever had could not be made to see the importance of crushing Oats till we showed him how frequently uncrushed Oats passed through the cows' stomachs undigested.

So far as is possible the calving of cows for the dairy of the home farm is so managed that at least one cow calves in each month of winter and spring in order to impart freshness to milk and butter. Dear-bought experience has repeatedly shown how important this is, for if there is no calving till spring the cows become "stale," and the butter becomes pale in colour and of bad flavour. Calving in winter and early spring happens while the cows are having what may fairly be termed a dry food diet, and it is precisely while they are so fed that there is much risk of milk fever. To insure safety from this so frequently fatal disease crushed linseed is used for a week or two before and after calving, a gallon being given in the morning and the same quantity at night, care being taken to soak it for twelve hours before use. This

WINTER DIET.

To dairy cows we assign the first place in our dietary, because dairy produce is affected by it in both quantity and quality. Sweet, wholesome, nourishing food, and plenty of it, must be given them in order that a full flow of milk may be

keeps the bowels open and renders the cows quite safe; but there must be a steady use of it morning and night, and no fitful careless practice, giving the linseed or not, as we may happen to think of it. In summer and early autumn, when the cows have plenty of grass, the blood is pure, and no linseed need be used.

We have not mentioned Mangolds among articles of winter diet, and must call attention to them as being of special value from the beginning of the new year onwards for the next four or five months. Failing a supply of Carrots they may be used from the present time, provided the roots are pulped, mixed with chaff, and left in a vat till slight fermentation has begun. Cabbage, too, now and onwards, is good if used in moderation. We by no means approve of extremes in this matter, and only use enough of such food to impart a wholesome degree of freshness and variety to the dietary without running the risk of spoiling the flavour of the milk. Silage was used successfully last winter, but we must own that the weather was so favourable for haymaking this summer that we have double our usual number of hayricks, but the silo is empty.

(To be continued.)

WORK ON THE HOME FARM.

The old sheep, principally crones, taken from the breeding flocks that were folded upon a second growth of Clover have thriven so well that we are sending weekly batches of them to market as fat sheep, and so far the prices realised are remunerative. We are now passing two flocks of such sheep over some rough pastures in folds, giving them 2 lbs. per head of crushed Waterloo cake, with a plentiful mixture of chaffed hay and barley straw. This plan answers admirably, the whole of the grass being eaten off closely and the pastures left in admirable order for a new growth. The most abundant plant in these pastures is the free-growing and nutritious Cocksfoot (*Dactylis glomerata*), of which we may rely upon a free, strong, early growth in spring, and as there are many loose stones upon it an early opportunity will be taken to have them picked off. Acorns are so plentiful again this year that a large quantity will be picked up and stored for winter use among the sheep. Glad are we to say that the Mangolds are at length cleared from the fields and the heaps made secure for winter. Heavy rain has somewhat hindered this work, as it has Wheat-sowing too. We are, however, so nicely forward with our ploughing and sowing, that a few fine days will enable us to get through with it. Drains are being put into wet land upon three of our farms where the land is both wet and poor. We quite agree with "W. M." that a hard substance put upon the drain pipes insures speedy and continuous action, and we are also entirely at one with him as to the value and importance of burning heavy soil for such a purpose, as well as for mixing as a mechanical agent in the soil. Apart from the question of burning for drainage, we have long advocated the paring and burning of foul land, applying the ashes so obtained as a dressing of manure for the next crop with highly profitable results. To those of our readers who intend having draining done this winter we strongly recommend deep rather than shallow drains, because we have not only to relieve the soil promptly of superfluous water from the surface, but also to prevent the ascent of water by capillary attraction from the subsoil to the surface. It is this latter reason for deep drains that is so frequently overlooked, and yet we know how quickly and persistently water rises and spreads in the soil, and how soil so water-logged remains chilled and inert, and no matter how freely we apply manure to it, the growth of crops in it are slow and the yield unsatisfactory. First of all let us be very careful in coming to a decision as to the necessity for drains, and then let our method of doing the work be as thorough and efficient as possible.

DRAINING.—"W. M.'s" remarks are admirable in theory, and if he can tell us how to burn clay into hallast at a shilling a yard I, for one, should adopt his advice in practice. I have tried in vain to get brick-makers about here to take a contract for burning clay (it is good red brick clay) into hallast at a reasonable price. They say it cannot be done. Coal here is about 10s. a ton.—C. W. D.

BALLAST BURNING.

BALLAST burning, its value to agriculture, and the method of conducting it, are subjects practically unknown to the farmer or land-owner, and yet with the abundance of coal we have in this country there is no reason why everybody interested in the improvement of the land should not look to a hallast heap as a source of profit, as certainly as he contemplates the familiar muck-heap.

The art of hallast-burning is exceedingly simple, depending for its success on the fact that all earthy matter is combustible, and that an apparently inert mass of damp clay contains elements which under proper conditions will burn, the result being that tenacious clay is converted into an insoluble, hard, and porous substance, whilst various earthy alkalies, more or less present in all clays, are separated from the clay during the process of burning, rendered soluble, and therefore able to perform immediately their function of stimulating plants with which

they may be brought in contact. We shall also see that there are many incidental uses for ballast upon a farm.

First, as to the method of burning. The implements required are a stout iron rake about 10 feet long and three-quarters of an inch thick, it should at least have three teeth; also a poker of the same length and thickness. A considerable quantity of the clay to be burnt is heaped up round a circular space, in which a fire is lit. At least 2 cwt. of rubbly coal should be employed to start this fire, and when the coal is well alight it should be covered to a depth of 3 inches with clay chopped into lumps about half the size of an ordinary brick. On the outside of the heap a dusting of small coal must be thrown; sufficient small coal to make the heap look thoroughly grimy is ample, for an excess of coal is a disadvantage. At the expiration of about twelve hours this heap will be burnt through, and it will be ready to pull down as soon as no smoke can be seen proceeding from it. When it is so ready a man with a shovel goes carefully round the base of the heap, throwing on one side the unburnt clay at the bottom of it; he then takes the heap down on to the base he has thus cleared, sprinkles the whole with small coal, then again puts on a coating of clay about as thick as before, finally dusting the heap again with small coal. This process goes on daily until the heap has attained considerable dimensions, say until there are 4 or 5 yards of clay burnt. When this is the case the layer of clay put on may be made thicker, until when there are some 20 yards of clay burnt the layer daily added may be at least a foot thick.

A few precautions must be observed. First, the wind must not be allowed to blow fiercely and continuously upon any particular part of the burning clay. This is easily prevented by shooting the clay as dug in a circle round the fire, and putting on the top of this circle hurdles wattled with straw. Second, when the fire is raked down every morning or evening coal must be put on the bottom of the burning heap more plentifully than on the top. Thirdly, the heap must be kept as perpendicular as possible, or there will be waste of fuel. The poker is used to regulate the angle of inclination of the heap before it is raked down, and also to ascertain if by any mischance the clay is burning irregularly.

When about 50 cubic yards of clay have been burnt it will no longer be possible to maintain the top of the burning heap in a conical shape; it must be made flat in the centre, rising gradually to the outer rim like the crater of a volcano.

Where limestone occurs in proximity to the place of burning, 1 yard of that stone may be thrown on to the fire to every 6 yards of clay. Quicklime will thus be produced without any expense other than that of the stone. In raking down daily a burning heap containing limestone, care must be taken not to rake down that stone. It must be allowed to remain as high up in the fire as possible.

I have already pointed out the great utility of ballast for drainage purposes, and of the fine stuff that is found in the heap as a manure for Potatoes. Ballast is also most valuable for road and path-making as a foundation on which to put harder material. It is also invaluable for building cottages; a mixture of six parts hallast, one part sand, one part cement or good hydraulic lime, well wetted and turned over three or four times, forms an exceedingly hard concrete. Any intelligent carpenter can fix boards between which this concrete may be filled, and when set the boards are removed, leaving a solid, inexpensive, and imperishable wall. I need scarcely say that a silo built of such walls, rendered with a mixture of good lime and sand, would be absolutely air-tight.

Small coal is the best fuel for burning hallast, but cinders, coke breeze, sawdust, may all be used with perfect success.—W. M.

OUR LETTER BOX.

Bromus giganteus (T. S.).—This forage plant will not usually produce like Italian Rye Grass when the imported seed is sown in the autumn and early spring months; and as summer forage we prefer Giant Sainfoin or Lucerne, both for quantity and feeding value, the latter especially when a quick succession is required as green fodder for dairy cows. There is, however, always the question of soil to be considered, and we therefore recommend a trial of these four sorts to ascertain which is the best.

REMARKS.

25th.—Fine throughout.
26th.—Rather wild, alternate heavy rain and bright sunshine; fine evening.
27th.—Fine and bright.
28th.—Fine but cool; drizzly evening.
29th.—Fair.
30th.—Fog in morning; cloudy afternoon; damp evening.
31st.—Heavy rain from 2 A.M. Rain at intervals all day, with gale in evening.
The heavy rain of Saturday has made this a wet week, though there was much bright weather in it, therefore the range of temperature was rather large for the season.
—G. J. SYMONS.

COMING EVENTS

12	TH	Lindfield, Walton, Portsmouth, Teddington, Staines, and Tunbridge Wells
13	F	Reading, Huddersfield, Canterbury, Cheshunt, and Exeter.
14	S	Ramsbottom.
15	SUN	TWENTY-FOURTH SUNDAY AFTER TRINITY.
16	M	
17	TU	Lincoln, East Grinstead, Yeovil, Devizes, Manchester, and Winchester.
18	W	Northampton, Bristol, Burton, and Birmingham.

PROPOSED INTERNATIONAL HORTICULTURAL EXHIBITION.

A LARGE meeting of representative horticulturists was held in the Music Room at South Kensington on Tuesday last, on the invitation of the Council of the Royal Horticultural Society, to take into consideration the proposal to hold a Great International Horticultural Exhibition in 1887.

The chair was taken by Sir Trevor Lawrence, Bart., M.P., President of the Society, supported by Members of the Council. Among those present we remarked H. J. Elwes, Esq.; W. Sowerby, Esq.; Bruce Findlay, Esq.; A. H. Smee, Esq.; W. B. Kellock, Esq.; Dr. Masters; Shirley Hibberd, Esq.; Messrs. O'Brien, W. Paul, John Fraser, George Paul, Harrison of Leicester, Pearson of Chilwell, Bunyard of Maidstone, Rivers of Sawbridgeworth, Cheal of Crawley, B. S. Williams, H. Williams, Woodbridge, &c.

After some introductory remarks by the President, setting forth the desirability of promoting a Great International Exhibition in 1887, he called on Dr. Masters, who had moved the adjournment of the last meeting to move the first resolution, which was as follows:—

"That in view of the great and increasing importance of Horticulture, and in order to preserve the high reputation in which British Horticulture is held by other nations, it is desirable to hold at no distant date an International Show and Congress of Horticulture in the widest sense of that term; and that the year 1887 being the jubilee year of Her Most Gracious Majesty the Queen, would be the most fitting time for such an undertaking."

This was seconded by Mr. Watts of Wiltshire and carried unanimously. The second resolution was proposed by Mr. Shirley Hibberd—

"That should Her Majesty's Commissioners of 1851 be prepared to afford adequate facilities, such a Show and Congress would be most advantageously held on some part of the Commissioners' grounds at South Kensington, provided that any use which the Commissioners propose to make of the rest of the grounds during the year 1887 be found to be in harmony with the character of the projected Show and Congress."

This was also carried unanimously. The third resolution was—

"That this Meeting requests the President and Council of the Royal Horticultural Society to take measures to ascertain the views of the Commissioners of 1851 on the matter, and assures the President and Council that should the proposals of the Commissioners be of such a nature as to afford reasonable hope that the Show and Congress may be carried out in a manner worthy of British horticulture, no effort shall be wanting on the part of those present to secure the success of the undertaking."

Proposed by Mr. Wm. Paul, seconded by Mr. A. H. Smee, and carried unanimously.

The fourth resolution, moved by Mr. Harrison of Leicester, and seconded by Mr. Cheal of Crawley, was as follows:—

"That this Meeting do now adjourn till such time as it shall be summoned by the President and Council of the Royal Horticultural Society, in order that the results of the negotiations with the Commissioners of 1851 may be laid before it."

This was also carried unanimously.

No. 281.—VOL. XI., THIRD SERIES.

A much more enthusiastic feeling seemed to prevail at this meeting than at the previous one, from the fact that the Exhibition is likely to be incorporated with whatever project is intended to be carried out under the auspices of the Royal Commissioners in celebration of Her Majesty's jubilee in 1887. We shall have some remarks to make on this subject next week.

GOOD PEARS.

Good Pears, and especially late varieties, are quite as much appreciated on the dessert table as Peaches or even Grapes are, but in many gardens late Pears do not receive the attention they deserve. In many cases the trees that supply fruit of these are old decrepit examples, and the fruit they produce is small in size, cracked, or otherwise miserable in appearance, and it cannot be expected under such circumstances that the flavour will be good. If gardeners would only bestow half as much attention on late Pears as was formerly spent on Peaches when they were grown more extensively on open walls than they are at the present time, we should not hear so many complaints against certain varieties as we are now in the habit of hearing.

Many varieties of Pears are often and truly described by gardeners and others as being of the first quality for dessert; and the same varieties are often as much disparaged by others. Judging by the Pears exhibited at the Pear Congress, and the numerous errors in nomenclature, it is quite evident that many varieties that are described as being first-class in quality at different times in the horticultural press, and then by others quite as much disparaged, cannot always be true to the name they are described under, for if they were true we should not have so much difference of opinion on certain varieties as we now have. For instance, in one collection I noticed that small and second-rate October Pear Eyewood named as Josephine de Malines, which, as any gardener knows who has the true variety, is one of the most delicious late Pears we have. In this very collection there were thirteen or fourteen dishes untrue to name out of twenty-four varieties; and in other collections we noticed third-rate Pears with the names of first-class varieties.

Soil and climate, we are aware, have a great influence on Pears, but it is quite certain that soil and climate alone will not always insure Pears becoming first-class in size and quality, as good and poor samples were sent to Chiswick from the same district, so it is quite evident that soil and climate, however good, will not produce first-class fruit without cultural attention. Many persons who visited the Conference with the intention of getting a list of the "best," were no doubt puzzled which to select, and that is not to be wondered at, for size and appearance in Pears is no criterion of quality, as it is more often the other way.

Having a fair knowledge of most of the good and useful Pears in cultivation, a list is appended of varieties that I have found first-class in flavour and fit to put on any dessert table; and, this being a good Pear year, I will invite others to send lists, so that we may discuss the merits or demerits of any variety; and if there is any doubt over the name of any variety under discussion, those who send lists can also send a fruit to the Editor, who would, I feel sure, endeavour to give its correct name. The following I consider good varieties:—Jargonelle, Williams' Bon Chrétien, Beurré d'Amanlis, Madame Treyve, Beurré Superfin, Louise Bonne of Jersey, Fondante d'Automne, Beurré Hardy, Comte de Lamy, Gansel's Bergamot, Thompson's, Marie Louise, Conseiller de la Cour, Glou Morceau, Pitmaston Duchess, Doyenné du Comice, Durondeau, Marie Louise d'Uccle, Emile d'Heyst, Beurre Diel, Beurré d'Anjou, Beurré d'Arenberg, Winter Nelis, Beurré de Jonghe, Josephine de Malines, Marie Benoist, Knight's Monarch, Passe Crassane, Bergamotte d'Esperen, Nouvelle Fulvie, Olivier des Serres, Easter Beurré, and Beurré Rance. The two latter varieties do not come good every season, but they are well worth growing. Easter Beurré,

No. 1937.—VOL. LXXVII., OLD SERIES.

although a late Pear, we have found to succeed better in the open than when grown against a south or west wall, but in the north no doubt it requires the benefit of a wall. What do others say on this Pear?—A. YOUNG.

VENNS' EARLY DWARF CABBAGE.

VARIETIES of early Cabbages, like some other things, are no doubt too numerous. However, when such a meritorious Cabbage as the above comes in our way we are bound not only to recognise it but to record the fact. After having grown it for three seasons I am persuaded that it has no superior. Among the many varieties we have grown this is the earliest, the dwarfest, and the hardiest, and so true is the stock that every plant is the very counterpart of its fellow. Another pre-eminent quality is it will not prematurely run to seed. Mr. Venns has frequently sown seed of it in March and allowed the plants to stand in the seed bed all summer, planting them out in the autumn, and not one of them has ever "bolted." It is of a most distinct character, and is easily known among other varieties.

In the autumn of 1883 I had the pleasure of sending some plants of it to Mr. Muir, Margam, who has great experience with vegetables new and old, and in the *Journal of Horticulture*, May 29th, 1884, Mr. Muir writes of it thus:—"It is the most compact-growing, earliest, and best of all our spring Cabbages this season. Not one of the plants bolted, and every one formed a massive head of fine quality. It is very distinct, and is certainly meritorious enough to be distributed as new."

I feel sure it will become one of the most popular of early Cabbages. To growers for market it will be quite a boon, as it attains to a fine size, turns in quickly, and has a taking appearance. This variety is in the possession of Mr. P. Venns, gardener to T. Tate, Esq., Allerburn House, Alnwick, by whom it has been selected and saved with the greatest of care for several years. I am so highly pleased with it that I have advised Mr. Venns to distribute it, and seed will shortly be offered in the advertising pages of the *Journal of Horticulture*.

I may add that I have not the slightest interest in the distribution of this variety, my only object in writing being to see a sterling article put into the hands of the public; and as vegetable-growing has been quite a fancy here for many years I am not without experience in judging on this matter.—JOSEPH OLIVER, *Eslington Park Gardens, Alnwick*.

ANNUAL MEETING OF THE YORKSHIRE ASSOCIATION OF HORTICULTURISTS.

ADDRESS BY THE REV F. D. HORNER.

[At the last annual meeting of the above Association, held at the rooms of the Paxton Society, Wakefield, the Rev. F. D. Horner delivered an interesting address upon the general objects of the Association, and this was supplemented by a lecture on the Auricula. We have been favoured with the MSS. of both these, and as they are of far more than local interest we present them to our readers.]

(Continued from page 398.)

THE earliest known florist varieties whose names have survived are a green edge and a white edge that were alive in 1757. Their names, Rule Arbitrator and Hortense, do not convey much meaning to us now. We only gather that, thus early, the grand class distinctions of edge were by that time attained and marked; but richness, decision, and purity, not common even now, were presumably far less developed than in the green, grey, and white-edged flowers. To look back through five and twenty years is to come to early days in the florist life of most of us, and all the great flowers in the three edges which we had then inherited were but three or four in each class. In green edges, always accounted first, by rarity, difficulty, and power, were Leigh's Col. Taylor, Booth's Freedom, Page's Champion, and say Litton's Imperator. In the greys, Old Ringleader (Kenyon), Lancashire Hero (Lancashire), and Geo. Lightbody, then a seedling of Mr. Richard Headly's only just about to come into circulation. In white edges, Taylor's Glory, Heap's Smiling Beauty, Ashworth's Regular.

The selfs of the period had the beauty and softness of colouring that these flowers seldom lack, and Campbell's Pizarro

was the coming champion, but none of them was perfect. Selfs are always largely produced by seed from the edged varieties, and it was supposed from this, that in trying for edged ones, selfs would abundantly come by the way and be prizes thrown in for nothing. It was by no means so. They are not to be thus lightly won. As a matter of fact I have never, to my knowledge, raised a first-rate self from edged parentage. All my best have been from carefully crossed seed of self parents. I do not say it has never been, or may never be, that a green edged flower may give a good seedling self, but an edged flower does not seem to know what a good self ought to be, judging from the many wild guesses and attempts over which it wastes such quantities of its seedlings.

In speaking of the properties of the florist Auricula, I will mention at the same time the faults and difficulties that have stood in the way. Some have of late years been overcome, notably that of the central notch in the petal of the self. The perfectly smooth round petal is a great point of beauty, and no self now not "rose-leaved" will hold any place as a first-class flower.

The pip or disc of the flower should be circular and flat. This is the best form for displaying the peculiar beauties of the Auricula. A conception of it in a diagram may, without doubt, look stiff and artificial enough; but it is not so in Nature, where every touch of softness and fulness, and every display of feature is added on those lines of beauty that man can imagine, but to which he cannot give the gentleness and touch of life. Immediacy of size in an Auricula is no magnitude of grace. No flower that I know suffers so much loss of beauty and refinement for being overgrown, or constitutionally big, as the Auricula. If ever a bloom is as large as a crown piece it is irremediably coarse. The size of a half-crown is too much, and that of a florin looks quite enough. At a shilling it begins to look small, and sixpence is too little. The number of pips that a plant will carry and finish well depends upon its vigour. A self will always carry more than an edged variety. The plant is often more vigorous, and the footstalks on the stem often longer and more yielding.

Eleven or twelve good pips are quite enough for a self to carry well, while less than seven will look a small truss. Seven good ones on an edged variety are much more for it than the like number on a self. Five upon an edged variety begin to look a small truss. Nine good pips will form a very handsome one. Any more that are left in will perhaps either overlap others or show inequality of size and weakness in one or more important points.

On an Auricula truss every pip has a wonderful individuality, and this must be preserved by not suffering it to be crumpled and blurred by overcrowding.

A very important feature of each flower is its tube, which should be circular and golden, well enriched with its coronet of proud gold-dusted anthers around its mouth. Faults of tube are pale green colours instead of gold or fading tones of yellow, as also a serrated edge and too great width and an irregularity of outline.

Next upon the flower's face lies a circle of white meal—technically the paste. This should be circular, dense, sharply cut, smooth, and snowy white. Its faults are thinness, narrowness, and waviness of outline. A bad paste and poor tube are both of them grave faults, visible through any brilliance of other properties. The golden tube and brilliant paste ought to be points in every flower. They are constant properties common to all the classes, and should be strong in all.

The next circle of colouring outside the paste is the ground or body. Colour, a velvety black, violet, chocolate, or maroon, or a tint difficult to describe.

It is a very beautiful feature and intense contrast to the paste. It should be perfectly free of any speck of meal, a velvet band, and solid on its inner edge near the paste. On its outer edge it flashes with pencillings of heavier or lighter style towards the edge of the flower; but these pencillings should in no part reach the petal rim. Faults of body are numerous. It may be too narrow, and look scratchy—too broad, and dash into the edge. Its colour may change as the flower ages, and the velvet may die off upon it prematurely. Meal may be scattered over it and make it impure.

The edge itself is a most beautiful and coveted feature in the Auricula. It is the outermost ring of colouring, and is a circle of pure green, or pearly grey, or snowy white, according to the total absence or varying depth of meal upon it. It is a difficult property, in the green and white classes especially, and its faults are not being pure from dots of meal, or from a tendency in some white edges to lose its whiteness for a damaging tint of yellow. Sometimes it is not broad enough, and less often too broad.

All the zones of colour on a pip should be well balanced. That is the idea of the proportion they should occupy on the flower. The eye can quickly tell if one zone or another trespass beyond its limits or fall short of them.

The full culture of this fascinating flower might be tedious to enter into here where so many of my hearers will not be Auricula growers.

I will therefore confine my remarks on this head within, I hope, convenient bounds.

The plant is perfectly hardy against cold, and all the protection we give it is either to keep off wet at unseasonable times, or to prevent its delicately constituted flowers from being ruined by weather, wind, and insects, such as bees.

It rests in winter and in summer, and grows most actively when the days are lengthening and shortening.

As to situation, I grow it in a south aspect from October to May, and in a northern one from May to October.

As a plant requiring but a small pot it is of course easily handled. Three-inch to 4½-inch pots will grow all in a collection.

Do not be dismayed at anything you may have heard about composts. There still lives in history the story of one who tried Auriculas in so many curious composts that the neighbours complained of the nuisance his raw materials were.

Someone suggested that he might keep a few geese—that would be profitable both for table and garden uses, goose droppings being one of the less noisome ingredients for Auricula composts. However one morning the geese got out into the garden and among the Auriculas. There was soon not one of them left, and so instead of being a means to an end they were the end of his means!

I have found very simple natural composts grow Auriculas well. I have never used a richer than equal parts of turfy loam, leaf mould, and sand (rough), or stiff loam, old hotbed, and sand; often kitchen garden soil, leaf mould, and sand.

I think the plants like firm potting, and certainly abundant drainage and charcoal in the soil if it be extra heavy. I always repot my plants "early"—i.e., just after the bloom, and in summer keep them cool and moist; in winter airy and comparatively dry. But they must have no coddling or be left to pine for fresh air. The staple enemy they have in the way of insects is green fly, and we are never at peace with him.

Offsets I take off, as they can be removed with any heel to them. Those only thus fit after October I preferably leave till the spring start in February. They need not be rooted at the time of separation. Seed I have sown any time between ripening and the following spring. It is very irregular in coming up, and I have young plants still appearing in a pan that will have been sown three years ago next spring.

If there is a plant that will thrive under difficulties of town life the Auricula is one, though of course, like all others, it prefers the country light and air.

I fear I have undertaken to say more than time permits me to say thoroughly. I am conscious of having grown rather sketchy in this paper, but I had rather disappoint you with too little than weary you with too much.

The one fault could be remedied if need were; the other not.

POTATOES.

"COUNTRY GARDENER'S" exceedingly pertinent remarks in the leader of 15th October point to the desirability of information as to the various properties of these noted prizetakers which year by year come before the public with their dainty proportions, but which, as he remarks, are doing so little for the public weal. Productiveness with quality are, he says, the essentials for the national food supply. To these qualifications I would add another too much overlooked—viz., relative exhaustion of the soil, and to this the weight of marketable tubers to be derived from a like number of picked shaws grown in proximity. The mere production of huge show Potatoes is of little importance if uneatable.

Unsuccessful as a contributor to the Chiswick experimental efforts, I have been led to consider the properties of my seedlings relatively to the field sorts most in vogue around in this the cradle of the famed Champions, the coast of Forfarshire.

In 1878 seeds were gathered from my own garden and the fields around, the parentage being Regents, Victorias, Dalmahoy, Champions, and many garden sorts. In 1879 the produce indicated the usual endless varieties of habit of growth, &c. About fifty varieties commenced with have been weeded down year by year to a dozen sorts. Finding, however, in Early Sandringham all I desire for an earliest crop, only three of the numerous kidneys are retained, and for several years the others have grown into field cultivation alongside Champions, Reading Heroes, Dalmahoy, and Magnums.

This district exports extensively to London and the southern ports,

especially in spring and early summer; hence, good keeping sorts fitted for use from March to June are of importance. In my selection the qualifications sought are full croppers (by weight), good boiling and keeping, moderate haulms, not unduly exhausting and clean lifting. All boil equally as well as the above standard sorts, but some of them possess the superior flavour of early days (1830 to 1840) long before disease was heard of. I am able only to give a tabulated statement of the past two years' produce relatively to that of the standard sorts. It points to the peculiarity of this hard dry summer in its sparser productiveness, and is otherwise instructive in that some sorts have been more affected by it than others.

Five picked shaws of each kind in 1884 and 1885 weighed as follows (field culture):—

	Magnums	Dalmahoy	Reading Heroes	Champions
1884	9 lbs			10½ lbs
1885	7½ lbs	7½ lbs	7½ lbs	8½ lbs

Seedlings (cultivated since 1879).

No.	15	18	20	23	27	28	34	37	39
1884	8½ lbs	9 lbs	9½ lbs	10 lbs	9 lbs	8 lbs	7 lbs	9 lbs	12 lbs
1885	7 lbs	7½ lbs	10½ lbs	9½ lbs	8½ lbs	7 lbs	8 lbs	9½ lbs	8½ lbs

The appearance of Magnums and Heroes was all that could be desired, while yet the weights were disappointing, and it may be found their displacement is excessive relatively to other sorts. Champions for the past two years have produced an over-proportion of small sizes, while the haulms of these three standard sorts are very heavy and hence exhausting. This property is avoided in the above seedlings; several of them are almost evergreen, being still green at this date (30th October), and yet they boil well. Potatoes of sorts are like Strawberries of sorts, they have their preference of habitat.—R. B., *Inchbrayock, Montrose.*

THE PRIMULAS.

(Continued from page 397.)

P. ELATIOR, *Jacq.*, the Oxlip.—Accepting this plant in the restricted sense it is comparatively rarely seen in gardens at present, although it is pretty common in copses and meadows in Cambridge, Suffolk, Essex, &c. It may be best described as intermediate between the common Primrose and the Cowslip or Paigle, and hybrids between the two latter species much resemble and are not always readily distinguished from typical *P. elatior*, which is also by many considered a hybrid, and in a broad sense one of the many links between the two species. The chief differences between *P. elatior* and *P. vulgaris* are the former's less inflated calyx, shorter stalks, and inodorous flowers, and from *P. veris* in the colour of its flowers, &c. It has been much confused, and the names by which it has at various times been known would almost fill a page. The following are a few of the principal:—*P. carpathica*, *Fuss.*; *P. Fluggeana*, *Lehm.*; *P. montana*, *Opinz.*; *P. Pallasii*, *Lehm.*; *P. intricata* var. *carpathica*, *Fuss.*; *P. Perreiniana*, *Flugge*; *P. alpestris*, *Schur.*; *P. inodora*, *Hffmög.*; *P. laterifolia*, *Goup.*, &c. It flowers in April and May, and may be readily established on slopes on the rockery, where its pretty drooping flowers are exceedingly pretty.

P. FARINOSA, *L.*—The Bird's-eye Primrose is a native of our island, though not by any means plentiful unless in one or two localities, the other stations being local. It has been long cultivated in English gardens, but with varying success; indeed in growing and flowering it well depends chiefly on the care and attention bestowed upon it. It is by no means a strongly constituted plant, and it requires to be watched through the winter, as it is liable to damp in low places. A perennial in nature, it will be found advisable in some localities to treat it as a biennial, that being the course adopted with great success in the case of the Scotch variety, *P. scotica*, *Hook.* To get seeds, however, is often another trouble, for even this tiny plant is not free from the ravages of a disease. It attacks the seed vessels, which on being collected will be found full of a smut caused by a fungus called *Urocystis primulicola*. When such is found to be the case the plants should be at once destroyed, for though there is no record of the disease attacking other Primulas there is always a danger while such a scourge is in the neighbourhood of the others, and the safest means is to burn the affected plants.

P. farinosa I have found to do best in a bog in rich peaty soil, keeping up the supply by means of seedlings, never depending much on the plants flowering a second year, although we have no doubt in favourable localities they will continue flowering for some years. It grows from 4 to 9 inches in height, carrying a head of pretty rosy purple yellow-eyed flowers, the tints varying much on the different plants. The leaves are obovate spatulate, crenated at the margins, glabrous, and covered with a white or sulphur-coloured meal. It flowers in June and July, and is found in bogs and meadows in Carnarvon, north of England, and Peebles, ascending to 1800 feet. *P. farinosa* var. *scotica*, *Hook.*, though quoted a

a species in the "British Flora." I am inclined to consider no more than a variety of *P. farinosa* (of geographical significance). It is a dwarfer plant than the type, deep blue purple flowers, and other minor differences. It flowers June and September, being confined in its distribution in this country to the north of Scotland. Syme states that *P. scotica* is not dimorphic, single plants seeding freely, also that it has three flowering seasons.

P. FARINOSA VAR. *WAREI*, *Stein*.—I place this here to save confusion, though stated by Stein to be a cross between *farinosa* and *scotica*, which is fully borne out on seeing the plant in flower. Stein states that he received this plant in 1876 from Mr. T. S. Ware of Tottenham as *P. scotica*. He considers it the best and easiest of the three to grow, every seed germinating. In the Breslau Botanical Society's herbarium there are two plants from Holland unlabelled, which he thinks to be *Warei*, and in Haage & Schmidt's catalogue for 1882 it is mentioned as *P. muroana* or *norvegica*, which he supposes to be a mutilation of *Warei*. I am inclined, however, to believe that *Munroana* is intended, as the plants we received under *muroana* turned out *P. involucrata*. The leaves of *Warei* are not unlike *farinosa*, unless in the absence of meal, the flower stalk short like *scotica*, as also is the shape of the flower, the colour being between them. It flowered with us in July of the present year. *Stricta*, *Horn.*, is another variety differing little from *P. farinosa*. The following are synonyms or slight forms: *P. oratensis*, *Gusmus*; *speciosa*, *Gus.*; *stricta*, *Gus.*; *denudata*, *Gus.*; *froudosa*, *Janka*; *Hornemanniana*, *Lehm.*, &c.

P. FEDTSCHENKII, *Regel*.—A new Turkestanian species lately introduced by Dr. Regel of St. Petersburg, somewhat resembling some of the forms of *P. cortusoides*, and equal in beauty to his handsome *P. Kaufmanniana*, also lately introduced under the name of *Kaufmannia Sewerzowii*. It seems to thrive best in a peaty soil in a shady not over-moist situation. We have not seen fresh flowers yet; but in the "Gartenflora" it is said to be equal in beauty to any from the European Alps, and likely to become one of our favourite garden plants. The flowers are of a deep violet-purple colour arranged in whorls one above the other, as in *P. japonica*. It grows about 6 inches or more high; leaves oblong obovate, almost sessile, and hardly crenated. It is figured in the first volume of the "Flora of Turkestan."

P. FLORKEANA, *Schrad.*.—This is figured in *Lehm.* "Monograph Prim.", 8, tab. 81, and also in *Reichenbach's "Flora Germanica"* (from which the drawing, fig. 64, has been prepared), where it is described by Schott. It is an extremely interesting hybrid between *P. superglutinosa* × *minima*, *Kern.*, but is described as having the foliage of *minima* and the flowers of *glutinosa*, and evidently varies a little under cultivation, as our plant has much larger leaves than *minima* that in all but the serratures resemble those of the other. It is an easy plant to grow, indeed one of the easiest of this class, bearing much sunshine, and flourishing well even in exposed places, which, by the way, should always be chosen for this plant. The soil should be composed of rough granite, sand, or small pieces of stone, with equal parts of peat and finely sifted leaf soil. The leaves are cuneate, tongue-shaped, dentate or sharply serrated, and about an inch in length. Scape a couple of

Fig. 64.—*Primula florkeana*
(*Reichenbach's Flora Germanica*)

inches high, bearing several deep lilac or almost violet flowers, surrounded by a foliaceous involucre. It grows with its parents on the Swiss and Tyrolean granite Alps at about 7000 feet. *Syn.*, *P. minima* var. *hybrida*, *Rech.*; *P. hybrida*, *Gusmus*; *P. intermedia*, *Tratt.* It is easily raised from seed.

P. FLORIBUNDA, *Wall.*.—A comparatively new species, having been introduced to cultivation only two years from the Royal Botanic Gardens, Edinburgh, the home for Indian alpine. It is a near ally of the Arabian *P. verticillata*, *Forsk.*, and included along with it in the section *Sphondylia* by Duby in De Candolle's "Prodromus." Although of recent introduction it is now by no means rare, as it ripens seed with the greatest freedom, which germinate readily either when gathered or in the spring; and by this means, saving and sowing from the plants that have been subjected to the hardest treatment, it may yet be possible to get *Primula floribunda* sufficiently hardy to withstand our severest winters. From what we have already seen of it the varying propensity seems to be great—almost double, semi-double, and different-sized and coloured flowers, all the result of a single sowing. My experience is not, however, sufficient to warrant their constancy. The seed, sown as

soon as ripe in the autumn, quickly germinates, and the plants undisturbed may be kept in a cool frame during winter, when they will be found ready for planting out in spring. Treated in this way and planted in the rockery they flower all through the summer, and in pots make fine plants for greenhouse decoration, enhanced by their almost incessant flowering. If planted on a dry well-sheltered spot on the rockery they may survive a mild winter, but a severe one will serve them as it does *P. verticillata* and *P. Boveana*. It grows from 4 to 8 inches high, bearing from two to six or more whorls of about a dozen flowers, golden yellow, over half an inch in diameter, and very ornamental. The flowers are on short stalks surrounded by short ovate leafy bracts. The leaves when fully grown are about 6 inches long, oval-shaped, pointed, coarsely toothed, and having reticulated veins. They are covered with a thick glandular pubescence. Native of the Himalayas, from 2500 to 6500 feet, from Kumaon to Kashmir; also in Simla, where it grows at 2700 feet on rocks and near springs of water. *Syn.*, *P. obovata*, *Wall.*; *Androsace obovata*, *Wall.*, *MSS.*—D.

(To be continued.)

FRUIT AND PLANT HOUSES.

(Continued from page 334.)

ASPECT is also important in relation to light and heat in the construction of houses for the cultivation of fruit or plants. If the house be a lean-to it will have the most light and heat when the sun is in a direct line with it at noon, or when the aspect is due south, and this holds good whatever be the angle of elevation. If the angle be 45°, then the sun will be vertical and the house derive the most benefit from the solar rays when the fruit of, for instance, Vines, Peaches, Figs, &c., subjected to early forcing is advanced for ripening. This accounts for houses with a sharp pitch, and lean-to's against a south wall being most eligible for the early forcing of those fruits, a matter, I think, too often disregarded in the erection of structures of this kind at the present time. There is nothing, however, without its disadvantages, for if we gain a certain benefit in early summer we have to contend against the solar influence when the plants need rest. The vertical sun (I mean vertical, or at right angles to the glass) causes what all cultivators are careful to avoid—viz., over-ripening of the wood and buds, as this is almost certain to result in premature development of growth and prove fatal to next year's prospects. This is guarded against by having houses employed for early forcing with movable roof lights, and to which I shall have occasion to refer again presently.

The advantage of the lean-to with a sharp pitch against a wall with a south aspect is considerable, the chief of which is a maximum of light. Another is that the north side, being of brick or other material, does not rapidly conduct heat from the interior, and an elevated and steady temperature is maintained most economically. It follows that if a lean-to with a sharp pitch, or say 45°, is good for early forcing it will also be most suitable for houses in which fruit is to be ripened in late summer, as we get in September precisely the same conditions as we do in April. For this reason I consider houses with a sharp pitch most suitable for late or unheated fruit houses. But we have to contend against the sun in the spring bringing on the trees or blossoms too quickly, and I only know one means of preventing this—viz., by moveable roofs, so as to prevent a too early development of the blossoms.

Then if we want our fruit crops ripe in summer, the aspect being the same or south, we are content with an angle of 30°, which I think the lowest elevation that ought to be used as a safeguard against drip and to carry off rain, as we then have plenty of light and heat, the difficulty being rather to guard against its scorching rays when the foliage is tender, and in autumn from taking the colour out of the Grapes to be kept, whilst our crops ripen. It does not matter much if we have the roof with an angle of 35° when we wish the fruit ripened from June to the middle of September, but I do not think the angle for general crops ought to exceed that elevation, as our present system of little wood and large panes of glass modifies our ideas of angles considerably.

An east aspect is bad, and a west one little better for a lean-to house, as the rays of light are for the most part reflected, and we not only have less light, but as less light is less heat we have the deficiency of the latter to make up artificially, consequently houses on those aspects are not so economical as those with south aspects. If the temperature of a house with a south aspect is influenced by the angle of the glass so also is that of a house with an east, west, and north aspect; if flat, the east and west, also north, are hottest at mid-summer—i.e., less rays are reflected; therefore, if we construct houses for coolness the angle should be such that most rays are reflected when the sun is most powerful. North houses ought, therefore, to have a rather sharp pitch, alike to throw off wet and prevent drip as to throw off the sun's rays, and so answer as retarding

houses or suitable for the successful treatment of plants injuriously affected by a hot and dry climate, as, for instance, cool Orchids and the Himalayan Rhododendrons or Ferns.

Aspect also considerably affects span-roofs both as regards their light and heat. If the span or the ends of the house run east and west, then we get half the surface with a south aspect, through which the sun's rays pass as in a lean-to with a similar angle and aspect, whilst the other half is facing the north, and the rays of light and heat are for the most part reflected. Thus we have the south side making the most of the sun's rays, whilst the north is cooling or wasting it, and the deficiency of sun heat has to be made up by artificial means; in fact, the economising of heat being the object, we lose fully one-third more of the sun's heat by having a span running east and west than would be the case were the same space covered with a lean-to facing due south. If we reverse the position and have the ends of the span north and south, then we secure sun heat during the best part of the day. The sun's rays are nearly as powerful at 9 A.M. as at noon, and there is no diminution of the sun's influence until after 3 P.M. By a span we avoid the scorching noon-day rays and secure a greater uniformity of light and heat; nevertheless, we lose much more light and heat than if we had the house of one uniform slope to the south, and in consequence more fire heat is necessary for the span-roof house than for the lean-to. I am fully aware that we do not employ more heating surface for a span than a lean-to, but we must bear in mind that, although the superficial area of glass required to cover a certain area with a span-roof is precisely the same as when the roof is a lean-to, the angle being identical, yet the height of the span-roof is only half that of the lean-to, and the space is lessened in the span proportionately. It takes less artificial heat for a lean-to than a span, the latter being less influenced by solar heat, which can only act upon one side at once. Although we lose heat in span-roofs, the roof being lower or more uniform than in the lean-to, they are very suitable for plants, as light being admitted on both sides equality of growth is more easily maintained, and there is also a further advantage in the span-roof—viz., the heat does not accumulate so much in the upper part as would be the case were one slope continued so as to form a lean-to. This latter consideration appears the only advantage sought in unequal span-roofed houses, and I take it as a decided one, especially over the lean-to, in preventing the accumulation of heat at the upper part, and when they have the longest slope to the south they are more economical as regards fuel than an equal span in the same position, owing to there being less glass or cooling surface exposed to the north; hence I consider them very suitable for fruit houses against south walls.

The aspect of ridge-and-furrow roofs is exactly the same relatively as those of span-roofs, and they are employed mainly in covering a large area to diminish the height of the roof, for were the area covered by one span or a single slope the height of the ridge of the span or the back wall must be considerable and ill-suited to the growth of dwarf or even moderate-sized plants. In regard to light and heat, there is a great difference between the ridge-and-furrow and one with a single slope, for though there is the same surface of glass, both being placed at the same angle, yet when the sun's rays are perpendicular to one side of the ridge few of them have any effect on the other side; whereas, in a roof with a single slope the whole of the surface is exposed to the sun, and twice the quantity of its light and heat is transmitted into the interior. The ridge-and-furrow, therefore, is heated as much by the sun as a span-roof, but very much less than by a slope, uniform to any aspect. I therefore dismiss the span and ridge-and-furrow with the observation that they are most suitable for plants where less intensity of solar heat is required, and where uniformity in growth is desired from an equal diffusion of light, also for fruits not wanted ripe until midsummer.

It only remains to consider the aspect of curvilinear roofs, which are similar to those of spans in general principles. If the ends are east and west only one side is having the sun's rays transmitted into it whilst the other is giving it off, and if the ends are north and south the same observations apply as to the span. But in a curvilinear roof we have the glass placed at such an angle that more light and heat is admitted, as the angle is more suited to the sun's elevation at different and all times of the day; hence, curved roofs admit more light than those which are straight. It must, however, be borne in mind that curved lines, if they admit more light and heat, transmit heat more rapidly from the interior, as the radiation is greater from the larger surface of glass than in straight-roofed houses. The angle of a curvilinear roof is, if I may use the expression, ought to be that of 45°—viz., the height of the back wall or to the ridge of a span should be that of the width, cutting off one-third from the width, so as to cut off the upper or flat part of the roof; so that if the house is wanted 24 feet wide and a span, the arc is described from 18 feet, and the width drawn in to 12 feet, half the width of the span, and we then get rid of the flat part of the roof, which is too flat on the full

curve to carry off the rain and drip. Such a house as a lean-to of half the width would be admirable for the forcing of fruits, and the span for a like purpose with the ends north and south when the fruit is required to ripen after midsummer, whilst for growing specimen plants, which ought to have light to their base, there is none better.—G. ABBEY.

ON LIFTING ROSES.

I AM of opinion that Roses are often allowed to remain too long in the same position, and am equally satisfied that even when the same spot is devoted year after year to their cultivation much advantage is to be derived from careful lifting and replanting, especially in cold ungenial districts, where the soil is naturally poor. Last autumn I determined to lift a bed of border Carnations and plant Roses in their place. The Roses I selected for the purpose had been growing in a bed for two years, which I determined to appropriate to the Carnations. After lifting the Carnations I had the bed well dug and enriched with manure and fresh soil. I then dug up the Roses carefully, shortened the longer roots, and replanted them without a moment's delay, with the result that every plant has done well, blooming better than those which were not lifted, and producing sturdier, shorter growth.

The lifting gives a slight check, which is, I am satisfied, beneficial to the health of the plants, and affords an opportunity for renovating the beds with fresh materials. It has also other advantages: it insures the better ripening of the wood, gives a longer period of rest, and retards the starting of growth in spring in an appreciable and beneficial degree. Every rosarian will recognise these advantages on consideration of their likely effects on his Rose trees.

Roses left too long in one place, especially when the soil is properly enriched with manure every year, are apt to grow too vigorously and to get overcrowded with non-productive shoots. My experience certainly is that the blooms on such long-standing trees, though more numerous than on newly planted trees, are distinctly inferior to them in size and finish. My advice is to replant some of the beds annually, and never to allow the trees to remain without lifting for more than two years. The roots will then be kept closer at home, and masses of fibre will be produced instead of long whip-like roots straggling all over the bed. I should perhaps add that I am writing about dwarf Roses (not standards), and particularly about Roses on their own roots. Perhaps I should add I am writing from a cold exposed situation, soil light, in the midland counties.—B. W. E.

NOTES ON CHRYSANTHEMUMS.

THIS has not been one of the best seasons for the well-doing of this autumn favourite, at all events here in Co. Meath. In the first instance we had frost far into the month of June, which injured the points; in fact they did very little from the middle of May until cut down or stopped about the middle of June. From this time they began to do well until the first week in September, when a continuation of strong winds from the west threatened to finish them. Through this I lost Mr. Brunlees, Refulgence, Beethoven of incurved, and Madame C. Audiguier, which I consider one of the very best of the Japanese varieties, at least of its colour it has no equal. Beside others I shall miss these varieties; however I have a very good supply left, looking very promising, the Queens especially, besides Prince Alfred, Lord Wolseley, Mr. Bunn, White Beverley, Lady Hardinge, Mrs. W. Shipman, White Globe, Jardin des Plantes, Princess Beatrice, and John Salter. Of Japanese, Hiver Fleuri, M. Delaux, Madame Bertie Rendatler, Colibri, Red Dragon, Chinaman, Thunberg, Comte de Germiny, Rosa Bonheur, Dr. Macary, Baronne de Prailly, and Comtesse de Beauregarde amongst others are very promising.

Your able correspondent Mr. Orchard has some remarks respecting earwigs (page 561), but I consider the best guard against this pest is to give the plants a good shake, which will bring them to the ground, when they may be easily captured. This should be repeated every evening at sunset. When housing be sure that every decayed leaf, or any that may be mildewed, be removed. The decayed foliage when dry makes a comfortable home for the earwig.

Another pest I consider as bad, or worse, is the cricket. I have seen flowers destroyed in one night by this. A very good trap is to get some white arsenic, say half an ounce in powder, also a quarter of a pound of lard; mix the arsenic thoroughly with an old knife. When mixed wash some pieces of slate or broken pots, and spread some of the mixture on them, placing them in or near their habitation will soon destroy them; a little sugar is sometimes mixed with it.

Judging Chrysanthemums at some of the shows is no easy task, especially in the cut-flower classes, where there is strong competition. Dublin is the only exhibition within my reach, and unless better than last it will not be of much account, neither was the judging deserving of praise. When we see reflexed flowers on a board of twenty-four incurved flowers, and this obtaining first prize, also Japanese flowers bearing the name of Large Anemone flowers, I consider it is time there was an alteration.—J. PITHERS.

THOUGHTS ON CURRENT TOPICS.

JUDGING from two or three pages of matter in the Journal last week the Chrysanthemum fever appears to be nearly at its height. There is not much wonder at the enthusiasm which is displayed in Chrysanthem-

mums. Gardens and conservatories would be gloomy now without them; numbers of persons with even small gardens and conveniences can grow them; they flourish in town and country, and no flowers answer to the whip better than these do—that is, show more strikingly the effects of good culture. Left to themselves, or imperfectly grown, they are bright yet small, flat and rough, but with attentive care and under skilful management the incurved varieties become marvels of symmetry, Japanese great mop-like masses of brilliancy, and the Anemones trim pincushion-like rosettes that artificial flower makers vainly try to imitate. The wonderful development of the Chrysanthemum and its great and rapidly spreading popularity is directly traceable to the competition that has been incited by the offering of good prizes at various and increasingly numerous shows. Not that one-hundredth part of the persons who grow plants better than before do so with the view of exhibiting them or their flowers in public; but they have seen what successful exhibitors have accomplished, and become animated with a desire to approach or equal them in the excellence of their work as cultivators. To succeed with many is a sufficient reward, and the determination to excel is in every way admirable. The autumn shows have incontestably resulted in marvellous improvement in this department of horticulture, and they are with few exceptions almost entirely supported by gate money. The promoters of these shows and the managers who make them so imposing as to bring in thousands of visitors with their shillings and pence, are scarcely engaged in an ignoble work. I, for one, applaud them for their endeavours, and regret I cannot more effectually aid them in the arrangements of such great floral feasts as will compel the multitude to come in.

IN reading the accounts of shows, public and private, with descriptions of new varieties one matter puzzles me—namely, the principle on which certificates are granted. It seems to me no light matter to grant such a high mark of honour to new varieties, because these are thereby enhanced in price on account of the great demand that follows for those that receive this official stamp of merit. Certificated flowers should, it seems to me, be undeniably distinct and possess decided superiority in some way, otherwise disappointment will ensue, mistrust be engendered, and a revulsion of feeling against new plants sooner or later created. Over and over again it is stated that a variety that was certificated last year—*La Purété*—is the same as one previously in cultivation—*Mdlle. Lacroix*. A mistake appears to have been made, and many growers seem to know it, yet, strange to say, *La Purété* is recorded as again certificated this season at Ealing. That circumstance appears to require explanation. Is the Ealing-honoured variety the same as *Mdlle. Lacroix*? and, if so, why was the error of last year officially confirmed last week? Perhaps some experts can answer this question. Enthusiasm is all very well, but unless governed by prudence and tempered by caution it may defeat the object its possessors desire to promote. That is my thought on this subject.

MR. HIAM asks me to give my opinion on canker in fruit trees, and then he will publish his reply that he has prepared to “*Entomologist*” which he at present withholds. I have no objection whatever to discuss this important matter, but I think the case will be more complete when Mr. Hiam has favoured with the publication of the reply alluded to. I am somewhat inclined to think there may be something in the theory he advances, of insects causing what is known as canker, but how much it is impossible to say so long as he withholds evidence in support of his case. Therefore, on considering the whole matter, I think I will wait a little longer.

“*A COUNTRY GARDENER*” suggests that I do not examine the articles to which I refer with sufficient care, and read between the lines attentively for clearly understanding the meaning that the writers intend to convey. I am quite ready to plead guilty in that respect, and in this case do so the more readily, since I have elicited a note that in all probability will be of service to many growers of Potatoes for use rather than ornament, and who are bewildered with the overwhelming numbers of sorts that are nowadays exalted as possessing such transcendent properties. Has “*A Country Gardener*” tried the two famous Reds that figure so prominently at shows—the Reading Russet and Vicar of Laleham, and if so will he obligingly state their cropping qualities, table merit, and period of use? I have heard conflicting opinions on them, and so, too, in all probability, have other gardeners who are not above growing Potatoes.

It is not often a more sound, seasonable, and instructive article appears than that by Mr. Bardney last week on pruning and lifting fruit trees. Cutting back the long, strong growths of trees in winter without checking the roots with the object of restricting growth is as vain as attempting to stop the production of steam in a boiler by twisting the valves about and at the same time keeping up a strong fire in the furnace. All luxuriant-growing trees that are exceeding their bounds and bear little or no fruit should be root-pruned now and have their growths suppressed in summer to prevent their encouraging such vigorous root-action as finds expression in exuberant wood that is essentially unfruitful in its nature; but how your correspondent catches “every moth” that lays the eggs that bring the caterpillars that eat the leaves, I know no more than the famous priest who contributed so much to the felicity of the house that Jack built. Perhaps Mr. Bardney will place us under another obligation to him by stating how he plays “old Gooseberry” with all these moths.

“*A KITCHEN GARDENER*” contributes a useful note on early Apples

on page 484. It is referred to because I observe he places three other sorts before Mr. Gladstone in point of earliness. I thought from what I had read that one of the chief points of merit of the “new” G.O.M. consisted in being at least fully abreast of all others, if not in advance; but it appears it is not. It may, however, for all that, be an excellent variety, and it is well to know the proper place of “*W. E. G.*,” a question that does not yet appear to be unanimously determined. Your correspondent speaks highly, but not too highly, of the good old Keswick Codlin, and if I were to venture an opinion it would be that the old favourite will be hale and fruitful for a hundred years after the large and light Lord Suffield has been “eaten” up with canker. Has “*A Kitchen Gardener*” grown the Domino that was advertised last year by Mr. Merryweather? I have seen trees of it this year wreathed with fruit heavier than that of Lord Suffield, and greener and larger than Keswick Codlin, also equal to either in quality and ready at the same time. I suspect this will prove a valuable Apple that will eventually find its way into most gardens.

BUT I must not forget “*Non-Believer*.” When I referred to his reappearance after a long absence I used the word *obscure* precisely as it has been applied under similar circumstances to myself. I should as soon think of describing the ex-Premier as an obscure individual as “*Non-Believer*,” though both may desire to remain in *obscure* for a few months, but not I think for long. I can enjoy a good retort, and even a “palpable hit,” if a fair one, like that in the first paragraph of “*Non-Believer*’s” rejoinder on page 404. But I do not think a long answer “always” indicates a weak case, as if it did my pugnacious opponent would have demolished me in fewer words. According to his own test, my position is rather strong, which is exactly what I feel it to be. “*Non-Believer*” has, I perceive, assumed a new character, but let me assure him of the uselessness of his thinking that by putting on spurs, donning a red coat, and brandishing a hunting whip, he can drive me away. I am too old to be frightened by a hogey of that kind. By the way, I wish Mr. Burhidge, or someone, would sketch that scene and send a couple of copies to the Editor for him to forward to us for framing. I think they would be appreciated, at least I can answer for one of them.

SERIOUSLY, I do not think that “*Non-Believer*” has as yet had anything to get excited about. What is the case? I honestly recorded a thought in half a dozen lines on page 313 on a matter of public interest, in which he was not even remotely alluded to. Thereupon he was tempted to transform my thought into a creed, and that “creed” a “carelessness as to whether the real objects of cultivating flowers or fruits is served or not.” He was thus the assailant, and absolutely without any justification for an attempt, however clumsy, at my personal or professional disparagement. If he had considered for a moment he must have known that “topics” exist before they are commented on, and a solitary “thought” cannot be legitimately magnified into a creed, whether it be good or bad.

As to the strained nonsense, for I cannot call it anything else, about the degradation of horticulture being embodied in the efforts to make exhibitions financially successful by attracting the public to them, and thus increasing the amount taken in admissions or gate money, it need only be said that if there were no money there would be no shows; and just as horticultural societies are supported with funds, just in the same proportion do they “encourage horticulture as a useful and humanising industry.” The Manchester and Shrewsbury Societies may be cited, among others, as conclusive examples of this; while other societies that could be named dwindle away by lack of support, and cannot—to quote “*Non-Believer*’s” words, which he quoted from somebody else—even “promote a taste for flowers and habits of neatness amongst the humbler classes.” Sentiment is all very well, but we have to deal with facts. Money, which “*Non-Believer*” cannot afford to despise, is the foundation of success in all good objects, and I heartily wish that every horticultural society had a good guarantee fund before making a show. That is what is wanted, and when it is non-existent “gate money” must perforce be relied on by the managers.

THE success of all industrial exhibitions, including those great ones at South Kensington, is absolutely dependent on gate money; it is the same with exhibitions of horticultural products, and if the directors of these did not study to make them so diversified and excellent as to attract the greatest possible number of visitors, and thus obtain the greatest amount in admission fees, they would of necessity fail, and the desirable spread of horticulture would not be advanced but retarded. The last provincial show of the Royal Horticultural Society was a case in point; gate money failed, and the Society was temporarily crippled. It will depend mainly on “gate money” as to whether the Great International Exhibition now projected will, if it be held, prove a success or failure, and it is certain those who are responsible will so make their arrangements as to induce a great influx of visitors as contributors to the necessary funds. The last great International Horticultural Exhibition in 1866 could not possibly have ended as it did had it not been continued for five days beyond the prescribed time. The money taken on the first three days was so inadequate for meeting the liabilities incurred, that the directors, the greatest horticulturists and botanists of the day, paid the exhibitors upwards of £200 for allowing their products to remain longer for the direct “purpose” of bringing more visitors and more money. The visitors came, some 80,000 of them, and were delighted, and left between £4000 and £5000 behind them. This insured the payment in full of every demand, and enabled a grant of £1000 being made to the

Gardeners' Royal Benevolent Institution. "Non-Believer" may, if he likes, call this putting horticulture on a "low ground" and thus degrading it. Most assuredly I do not, and so far from "repudiating," I emphasise what I have said on this subject, and with all due deference I venture to submit it is not for "Non-Believer" to accuse me of evasion.

Now a step further. I have said too much for my critic before, but fail to see that fact should deter me any more than the hunting whip does from saying still a little more. When I asked "Non-Believer" on page 378 if he is in a position to say that he has "never exhibited Grapes that were not ripe and in the best condition for table," it was with the object of testing his sincerity as to the practice being "indefensible." This has nothing whatever to do with gate money. It is a separate subject to which he devoted a separate paragraph on page 342. If "Non-Believer" is a good sportsman he will keep his "nose to the fence" and not "turn tail." He has not answered that question, but "fenced" with it. I repeat it, and further ask if he has never exhibited late Grapes in the autumn. If he can give a clear, unqualified negative reply he will strengthen his position immensely; if he cannot he stands condemned of doing that which he has characterised as "indefensible."

As to his simulated horror of putting horticulture on a "low ground," because, forsooth, shows are made so good that they attract the public and bring gate money for disbursing in prizes, I cannot help thinking the protest does not come with the best of grace from an individual who does not show now because from a "pecuniary point of view" he can "do better." He must have exhibited at some time, or he would not know how much or how little money he could make, and thus find out how he could "do better," or make more in some other way. I do not blame him if he is repentant of what he may regard as past errors in receiving a share in the gate money of shows, but notice his significant admission. I observe, too, "Non-Believer" does not dispute the existence of individuals who are so exacting for their "pound of flesh" as to have threatened managers of shows with actions, nor does he ask for an example. I am inclined to think the "dust" I "throw up" does not "confuse spectators" so much as it confuses my assailant, who, with his usual taste, chooses to make a personal matter of a public question. I regret he has done so, not on my own account, but in the interests of horticultural literature. His mock heroics can deceive no one, and his distortion of sentences and characteristic equivocation are, to employ a mild term, pitiable. Perhaps sufficient has been said on this subject at present by—A THINKER.

VEITCH MEMORIAL PRIZES FOR 1886. — We learn that the Trustees of the Veitch Memorial Prize Fund have decided to offer next year the following prizes, the dates for which and other particulars will be announced later on:—At Stoke-on-Trent, a Veitch Memorial medal and prize of £5, for a group of Orchids with Ferns intermixed; at Stoke-on-Trent, a Veitch Memorial medal and £5, for a mixed group of flowering and foliage plants; at Exeter, a Veitch Memorial medal and £5 (subject not determined); at Royal Botanic Society, Regent's Park, a Veitch Memorial medal and £5, for twelve Amaryllis; at Royal Horticultural Society, South Kensington, a Veitch Memorial medal and £5, for a collection of forced salad plants.

— At the Brixton Show, briefly reported last week, there was a very pretty display of ORCHIDS, Mr. Salter, The Gardens, Selborne, Leigham Court Road, Streatham, contributing largely, for besides several entries in the classes, he had a beautiful group of well-grown plants. These included some fine examples of *Vanda coerulea*, one of which had a spike of sixteen large flowers. *Cattleya Dowiana* and a darker-coloured variety with golden sepals and petals termed *aurea* was also notable, and with *Odontoglossum Pescatorei*, *Phalenopsis amabilis*, *Cattleya imperialis*, and *Cypripediums* made a most effective group arranged with Ferns. Mr. Weston, Clapham Park, had a good plant of *Zygopetalum crinitum* bearing two spikes of seven flowers each, and Mr. Luff also showed several well-grown plants.

— In the fruit classes at the same Show Mr. W. Hall, Tulse Hill, had three superb bunches of ALICANTE GRAPES, weighing 12 lbs., the berries even, of good size, and finely coloured. For evenness and finish they were some of the best we have seen this year. The best white Grapes were from W. Roupell, Esq., Roupell Park, well-coloured medium size bunches of Muscat of Alexandria. Apples and Pears were well represented, Messrs. A. Sandy and W. Hall being the principal prizetakers.

— MR. JOSEPH OLIVER states:—"The weather in Northumberland is most beautiful this week, some days being more like spring than November, and quite a treat after such a long run of unsettled weather."

— At the risk of making one of our correspondents vain, we are tempted to publish what Mr. Oliver sends respecting him. Here it is:—"We are pleased to see 'Thinker' on again; all the readers of the Journal that we fall in with from time to time are highly pleased with him, and consider he is doing a good thing in a capital spirit."

— WE have received an illustrated catalogue of RIPPINGILLE'S OIL-WARMING STOVES, in which the different forms are represented, showing their adaptability to various domestic purposes. Silver medals and certificates of merit have been awarded to these stoves, which many amateurs have found useful in excluding frost from small greenhouses. They are manufactured by the Albion Lamp Company, Birmingham and London.

— A CORRESPONDENT, "Sutton," will be glad if W. J. Ireland will state his method of PACKING GARDENIAS to travel safely; and "Sutton" is of opinion that many other readers will be glad to know the best way of packing these flowers.

— THE EAST GRINSTEAD CHRYSANTHEMUM SOCIETY will hold their annual Show in the Public Hall of that town on November 17th. Thirty-six classes are provided, of which twenty-six are for Chrysanthemum plants or blooms, and the remainder are for table decoration. Primulas, Grapes, Apples, and Pears. The prizes range from 25s. to 1s. 6d. Mr. Jenks, Brambletye, is the Hon. Sec.

— A CORRESPONDENT writes:—"In Messrs. R. P. Ker & Son's nursery, Aigburth, Henderson's WHITE PLUME CELERY is growing in two or three rows, and every plant is true and answers exactly to the character given it when sent out. The foliage is beautifully variegated, and the stems blanch without the trouble of earthing them. In fact, all the inside stems are naturally white. Having tasted it under these conditions it did not possess that crispness characteristic of good Celery. In spite of this it will prove a valuable acquisition for stewing in establishments where quantities are in request for this purpose early in the season."

— "LARGE quantities of CYCLAMENS are also grown in the Aigburth nursery, and are just now remarkably fine. The plants number many hundreds, in pots varying from 5 to 7 inches in diameter. The whole are from seed sown last year, and have, therefore, been grown in little more than twelve months. Those in the largest size are about sixteen months old, and wonderful examples of cultivation they are, for many of the plants are as many inches through them as they have been months growing. They are also flowering with great freedom, for many of the plants have already scores of their beautiful sweet flowers well above the foliage. Mr. Ranger has certainly proved himself to be a master in the cultivation of the Cyclamen in past years; but the plants he has grown this year are certainly superior to any of his previous productions."

— A GARDENER recommends "Those who have not grown BEGONIA CARRIERI to do so, for it is a gem, and flowers with great profusion during the autumn and winter months. Where white flowers are required for cutting, or plants for decorative purposes in various size pots, it is undoubtedly one of the best plants that can be grown. It appears to be a good grower, of free branching habit, and flowers so profusely that the smallest plant—even those just rooted—soon becomes a mass of bloom. The white flowers which are produced in clusters are displayed to great advantage by the dark foliage of the plant. It does not appear very particular about treatment or position, for it continues growing and flowers freely in the conservatory where a temperature of 45 to 50° is maintained. The plants grow into shapely bushes without much trouble as regards the pinching of the shoots. Its good habit of growth, therefore, renders it a very suitable plant for using as single specimens in vases. But for the embellishment of the conservatory during the dreary months of the year we think it invaluable."

— THE dwarf-growing evergreen shrub, VERONICA TRAVERSI, flourishes in the neighbourhood of Liverpool, and is admirably adapted for planting in town gardens. The greatest recommendation in its favour is the character it possesses of growing well under the shade of trees. Plants that flourish in such positions are well worth noting, for very few do well for any length of time subjected to drip and shade in such situations.

— A NORTHERN correspondent writes, "My CHRYSANTHEMUMS are from ten days to a fortnight late this season owing to the unusually cold and wet autumn in this district. I have a very smooth lot, but I am under the impression that some of the varieties will be rather under their usual size, and, so far as I can see at present, the petals are rather fewer in number, owing, in my opinion, to a deficiency of solar heat and light in the autumn. The only varieties I have expanded are Jeanne d'Arc., Lady Hardinge, Mrs. W. Shipman, Refulgence, Mr. Bunn, Beverley, Golden Beverley, Mrs. Dixon, Mrs. Rundle, and George Glenny—ten varieties. My best flower so far is Mr. Bunn, a good, solid bloom, measuring 9 inches over and 13 inches in horizontal circumference."

— MR. E. W. BADGER writes as follows on CURING DISEASED EUCHARISES.—"After reading 'W. W.'s' note on this subject it occurred to me that the recently introduced remedy for mildew, red spider, aphid, &c., is one which might most probably be effectual in this case. I refer to sulphide of potassium (Harris & Co), which has been favourably reported on by several of our best gardeners. I am only judging by analogy, but I am persuaded that there is every chance of it proving destructive to the Eucharis mite without being in the slightest degree hurtful to the bulbs; indeed, it will most likely do them good by arresting any decay which may have begun in them. A weak solution only is necessary—namely, quarter of an ounce of the sulphide dissolved in a gallon of water. I would suggest two modes of experimenting. 1, To plunge the plants in pots in the solution until the soil is saturated; and, 2, To wash the bulbs thoroughly in it. This suggestion is not intended to supersede 'W. W.'s' method, but to supplement it. Anyone trying the sulphide will render service to gardening by reporting the result in the Journal."

— HULL CHRYSANTHEMUM SHOW. — A photograph of the challenge vase that is provided for open competition at Hull on November 19th has been sent to us. The vase is evidently a very beautiful one and such as will be prized by its fortunate possessor. Its value is fifteen guineas, and there is £10 in addition for the winner, the other prizes in the same class being £8, £5, and £2; or £25 (excluding the vase) for twenty-four incurved blooms in not less than eighteen varieties, and twenty-four Japanese under similar conditions. This ought to insure fine stands and good competition. Other substantial prizes are provided in the schedule. The Show continues for two days.

— "W. B." observes that BEGONIA SEMPERFLORENS ROSEA is an excellent variety for flowering during the dreary months of autumn and winter. It is a robust grower, and flowers profusely in the stove, but soon becomes tall in the close moist atmosphere of that structure. It is, however, well worth growing, for it appears to greatest advantage when its stems and flowers stand out well above surrounding objects. For this purpose the plants should be grown in small pots with single stems. It branches freely from the base if larger plants are desired. This variety is probably most suitable for the conservatory where the temperature does not fall below 50°, or any intermediate structure. Growth under these conditions is slower than is the case when kept in the stove. The trusses of flowers are crimson in colour, and borne on strong, rather lengthy stem, after the style of *B. nitida*, but the individual flowers are larger than those of that variety. *Begonia semperflorens carminea* is very similar to the above variety, and is also well worth growing, the only difference between the two being the size and darker shade of colouring in the flowers.

— A FARMER writing in the *Florida Dispatch* respecting INDESTRUCTIBLE FENCE POSTS, observes that twenty-five years ago he set split white Oak posts for his garden fence, putting about a peck of air-slaked lime about each, and they are all good yet. He attributes their good condition to the effect of the lime, in which he is doubtless correct. A board that has been used in a mortar bed, and thoroughly saturated with lime, is almost indestructible from decay.

— PTERIS TREMULA.—Mr. W. H. Divers writes:—"I notice 'W. B. H.,' page 402, recommends this Fern for indoor use where no gas is used, and I can endorse all he says in its favour. I have often found it stand well when grown in rooms, &c.; but in conversation with some ladies a few days since they gave it a much stronger recommendation, as they told me it was the only Fern they could keep alive any length of time where gas was often used. I have noticed *Pteris cretica albo-lineata* also does well under adverse circumstances, but I have never found any

plant so useful as *Aspidistra lurida variegata* for growing in very bad positions in rooms."

— At the ordinary meeting of the ROYAL METEOROLOGICAL SOCIETY, to be held at 25, Great George Street, Westminster, on Wednesday, the 18th inst., at 7 P.M., the following papers will be read:—"The Helm Wind of August 19th, 1885," by William Marriott, F.R.Met.Soc. "The Typhoon Origin of the Weather over the British Isles during the 2nd of October, 1882," by Henry Harries. "Note on the Principle and Working of Jordan's Improved Sunshine Recorder," by J. B. Jordan and F. Gaster, F.R.Met.Soc. A Committee of the above Society has been appointed to take into consideration the question of the supposed DIMINUTION OF WATER SUPPLY AND THE SUGGESTED INCREASE OF FLOODS. The Committee is desirous of obtaining as much information as possible, and will therefore be very glad to receive any data bearing upon the subject, and showing the past and present state of the water supply, either from gaugings of wells or springs; the height of flood marks in rivers, streams, and lakes; the records of low water periods; or any historic data which may have been collected relating to the subject. Information relating to the period between 1825 and 1835 would be extremely valuable, in order to enable the Committee to fill up a gap in the diagram accompanying the report in the "Quarterly Journal" for July, 1885. All communications should be addressed to the Assistant Secretary, Mr. W. Marriott, 30, Great George Street, Westminster, S.W.

NOTES ON NEW AND RECENTLY INTRODUCED VEGETABLES.

THE experience of another year enables me to speak more fully and conclusively of the merits of some of our new vegetables than I have hitherto been capable of doing.

CHOU DE BURGHELY.—The seed of this was sown in April, and I am glad to find it is now perfectly true in character. There are no tall narrow ones here, and broad short ones there, but all are of that compact conical form which distinguishes the true variety. It has turned in well, and when cooked like Cabbage it is more delicate and delicious than any Cabbage I ever tasted. I am more satisfied with it this season than ever, and all who desire a Cabbage of great excellency should grow it. I am not going to say anything of its Broccoli character. I fear none of our heads will ever reach the Broccoli-forming stage.

SUTTON'S EARLY SNOWBALL TURNIP.—There are many Snowball Turnips, but this is the finest of all. It is most handsome in shape, pure white throughout, and of the highest quality. We cultivated more of it this year than on any previous occasion, and it has taken its place as a standard sort in our garden. Some object to seed firms putting their name as a prefix before vegetables, but were it not for this plan such a Turnip as this would not be known from other Snowballs, and it certainly merits distinction. It is superb for exhibition.

VEITCH'S AUTUMN GIANT CAULIFLOWER.—What! this amongst new vegetables? No; but it is amongst good ones, and I am sure no one can ever think of the best vegetables without this Cauliflower appearing amongst the first. We have been cutting it for upwards of three months, and shall continue for about two months more. I would as soon think of being without a Cauliflower altogether as omitting this one. There are those who think that any seedsman can supply such gems as this as well as going to head quarters, but it is not always so. Some years ago I had seed of this Cauliflower from a respectable firm in the north, and was greatly mortified to find that the majority of the plants were untrue. I could see this before the plants headed, and they disarranged the Cauliflower supply so much that autumn that I resolved to always go to head-quarters for specialities.

GILBERT'S UNIVERSAL SAVOY.—Seed of this was sown at the same time as the Drumhead and Green Globe. Some of these two are just ready for cutting now, and others will not be fit for some time; but the Universal has been ready since the middle of September, and scores of them have hurst, as they came in quicker than there was a demand for them. This early heading and splitting disappointed us, but it should be sown six weeks or two months after any other Savoy. It does not grow very large, and may be planted much closer than other Savoy; 15 inches between the rows, and the same between the plants, would be ample space. Owing to this early heading I shall have none of it by mid-winter, and shall require another season's experience of it before recommending it.

WHITE PLUME CELERY.—This novelty becomes a greater favourite by extended cultivation. I had some seed sent from New York again in January last, and it has turned out true. Some might think it a little wanting in crispness when used as salad, but for cooking purposes it is excellent, and for this alone quantities of it should be grown everywhere. Its culture is most simple; indeed planting and weeding is the whole of the details necessary for its successful culture.

ONIONS.—Webb's Banbury continues one of the best of summer varieties. It is evidently cultivated with great care to keep the stock pure, as for the last half-dozen years at least one crop has resembled another as closely as possible. I have some specimens which weigh

1 lb. 2 ozs. They are sound and finely formed. In my opinion there is no foundation for calling Rousham Park Hero a "new variety of the White Spanish." A selected White Spanish would be more appropriate. I could place it with some others and defy the raiser to distinguish it. It is a fine Onion under extra good cultivation. I do not think we pay enough attention to the culture of small Onions. If anyone would advertise an Onion that would readily become 1 foot or so in diameter, the demand for it would be unlimited, but one from 2 to 3 inches in diameter would pass unnoticed, and yet when usefulness, and above all, keeping qualities are considered, the small ones are the best. In this respect Carters' new Golden Queen merits general culture. It is one of the miniature varieties, just what good cooks ask for very frequently, and is a first-rate one to keep for six or eight months.

LETTUCE.—Veitch's Perfect Gem is the most compact growing of the Lettuces, and of good quality. Webb's Summerhill is another Cabbage variety greatly liked in the house here. Last July we had it 7 lbs. in weight.

LAXTON'S GIRTFORD GIANT KIDNEY BEAN.—I have grown this exclusively this season, and I do not think we ever had finer crops. It is early, prolific, and bears very large tender pods, but many of our pods were gathered when 4 and 5 inches in length, and only those for seed remained to attain a length of 10 inches and 1 foot. Although I have only possessed it two seasons, it has been so uncommonly good throughout that it is now, and will be, our main crop sort.

TOMATOES.—Reading Perfection and Hackwood Prolific are two of the finest of recent introductions. Both are large in size, even in form, and highly productive, but I know of some good judges who do not look upon great size and fine symmetry as the main points of a Tomato, and for this reason they prefer Carters' Green Gage to all others on account of its exquisite flavour.—A KITCHEN GARDENER.

REVIEW OF BOOK.

The Flowering Plants and Ferns of the Riviera and Neighbouring Mountains; drawn and described by C. Bicknell. London: Trübner and Co.

THIS elegant work has appeared at an opportune season. The time has arrived when invalids seeking health, workers seeking rest, and the luxurious long for the comforts that the charming climate of the Riviera and its neighbourhood afford, are directing their faces toward the Mediterranean coast. The only drawback to a winter spent in these regions is the want of occupation—something to amuse, and at the same time to instruct. All feel the general monotony that sets in after the visits to Monte Carlo, Nice, and Bordighera have been made and the few mountain ascents have been accomplished. The flowers with which these mountains are clothed have a never-failing attraction, and the very absence of occupation that visitors suffer from tends to strengthen the love which the never-failing flowers engender. What has always been a desideratum among the visitors of the Riviera was a book that would assist them in discovering the names of the wild flowers. There are several local floras, such as Ardoino's, but they are regarded as too scientific, and, being written in French, even those who are familiar with the language are not also familiar with its technical terms, and hence all the works we have seen on the subject are really sealed books to the great majority of sojourners on the Riviera. Mr. Moggridge's "Contributions to the Flora of Mentone," is an expensive book, and has become rare, and was really out of the reach of the many. We therefore hail the appearance of "The Flowering Plants and Ferns of the Riviera" as a much-needed requisite to the full enjoyment of a visit to this region, and, being written in English, it is equally valuable to English and Americans, both of whom are to be found there in ever-increasing numbers.

The work consists of eighty-two plates, with the requisite letterpress arranged according to the Natural System, and each plate contains two or more figures of allied species, embracing 221 species altogether of the most beautiful objects of the Alpine Flora. The author deserves great praise for the care that has been taken in the preparation of the work, and for the fidelity and artistic skill which has been shown in the drawing of the plants.

We observe there are a few errors which have escaped the author's notice. *Ranunculus monspeliacus* is said to be 2 to 3 *diameters* high, for *decimetres*. In plate xiii., and also in the text, *Cytisus sessilifolius* is spelt *sessifolius*. In plate xvii., and also in the text, *Lotus tetragonolobus* is spelt *tetragonobolus*.

TWO ROCK GARDENS IN THE NORTH.

DURING my visit to Manchester and Darlington in July I had the pleasure of visiting two gardens wide as the poles asunder in their character, but both evidencing how widely spreading is the taste for alpine and herbaceous plants, and how one comes upon them in the most unlikely places. One was that very largely known one of Mr. Harvey's at Aigburth, near Liverpool, and the other in an allotment ground at Newcastle-on-Tyne; and knowing how very general is the taste for these things, I imagine that a few notes will not be uninteresting to the readers of the Journal.

A villa garden is not the place where one (knowing what villa gardens generally are) would look for a picturesque and well-furnished rock garden; but Mr. Harvey's is not an ordinary villa garden, and I wish I could adequately convey an idea of the excel-

lent taste with which it is arranged, and the richness of the collection it contains.

The garden is situated about five miles from Liverpool, and stretches down to the banks of the Mersey, while in full view of the house (but, alas! hidden by mist the day that I was there) are the mountains of North Wales. From its open situation it is a place where rude Boreas, sweeping down from the Welsh mountains and coming across the rivers, causes his presence to be felt, and compels the owner to put up various defences against his attacks. The soil, too, is not in Mr. Harvey's favour (how often one finds this in rock gardens), as it is a stiff clayey loam not by any means suitable for the growth of alpine plants. In front, the lawn (for the inevitable tennis) stretches down towards the river, and from this there is a wall of separation in the form of a Beech hedge about 15 feet high. Some Lilies in the herbaceous garden were grand in their development—*pardalinum* in great masses, *auratum* 4 to 5 feet high with clusters of blooms, *Washingtonium purpureum*, &c., all very much at home, and returning much for the loving care bestowed on them.

I was, however, mostly interested in the rock garden. I have seen some grand gardens, and Floore especially was fresh in my memory, and I thought had satisfied myself for one season. The collection at Aigburth is neither so extensive nor does it exhibit such triumphs as Mr. Loder's does; but it is without doubt an exceedingly rich and valuable one. We used to be told that nothing could be done without pockets, the said pockets destroying the naturalness of the rockery. But there are no pockets here, and as a consequence the rockery is much more natural, while the plants seem to do equally well, different kinds of stone having been used to suit the requirements of the plants; for although some have doubted whether it is so absolutely necessary to provide lime for what are called limestone-loving plants, there can be little doubt that they are happier when their natural wants are provided for.

To enumerate the plants in this very rich collection would be to simply copy out a very select catalogue, and a better idea may be given of the success which has attended Mr. Harvey's effort if I give some of the most striking results. Here is a patch of the very beautiful *Androsace sarmentosa*, which covers a space of several feet, and which so strangely alters the character of its foliage; *A. lanuginosa* was also fine. This was arranged so that the crown could be easily protected by a pane of glass, for it is one of those plants which suffer from the excessive moisture of the winter. *Lithospermum prostratum* was flourishing, while there was a fine collection of *Primulas* of various sorts—*Munroi*, *latifolia*, *rosea*, *viscosa*, *nivalis*, *cashmeriana*, &c. That beautiful but somewhat capricious plant *Ourisia coccinea* was also doing well, and so also *Onosma taurica*. There was a grand clump of *Mazus pumilio*, *Nierembergia rivularis*, *Convolvulus mauritanicus*, and *Campanula pulla*. *Campanula Allioni* is also doing well. There was a grand clump of *Hypericum reptans*, and I was very much surprised to find *Lilium auratum* treated almost as a bog plant. It was in a portion of the garden sunk below the level, and the stems were from 4 to 5 feet, covered with blooms. *Phyteuma comosum* was at home, although hardly so much so as at Floore, but then it had not been planted so long, and probably when it has had time will do as well. The garden is rich in *Campanulas*, and I met there some varieties I have not seen before, although perhaps common enough. *Campanula pelviformis* struck me as very beautiful, and also another variety raised at Aigburth; *Campanula garganica* flowing over some pieces of rockwork was in fine condition.

There is also a very pretty little bog garden where many things are flourishing in better condition than one often sees in artificial bogs. Here some of the *Spiræas* are at home, as well as some of those *Primulas*, such as *rosea* and *luteola*, and *Munroi*, which like such a place. Here, too, our pretty native plant *Pyrola rotundifolia* is flourishing. Here, too, some of the Ferns, such as *Osmunda regalis* and *Woodsia ilvensis* are doing well; and in fact so carefully are things looked after that there are few failures, and most things are doing as well as can be. Mr. Harvey is also affected with the Orchid mania, and has a very good collection.

The other rock garden was of a totally different and, I venture to say, a perfectly unique character, for great was my astonishment after the Newcastle Show to be asked, "As I know you are interested in rock gardens would you like to see one in an allotment?" "By all means," was my reply. "It is not far off," was the statement, and so in truth I found it—almost in that peculiarly grimy city. I went—of course expecting to see some cockneyfied production of heaps of stones or old bricks, with plants dotted about in pockets amongst them, for what could there be in an allotment garden? I was most agreeably undeceived. It appears that there is some property about which there is a difficulty. It cannot be sold, and so has been let out in allotments. These are quite secluded one from the other, and this when we entered it might

have been any distance away. The entrance is formed of Ivy, and the door actually turns on a hinge of Ivy. The size of the piece of ground devoted to the rock garden is about 110 feet by 50. The stones used in the formation are obtained from the neighbourhood of Newcastle—the sandstone of the coal measures—a stone which adapts itself well to the formation of a rockery, and I may say that I have never seen a more natural and charming piece of work. You might really imagine yourself on some sandstone ridge which Nature had luxuriantly clothed. There was also a small piece of water on which a white Water Lily was reposing, and its flowers as pure as could be had on any mountain tarn. It would be impossible to get many of the alpine rock plants to flourish so close to a smoky town like Newcastle, and therefore very wisely Mr. Wilson, the owner of the garden, has relied mainly on the Saxifragas, Sedums, and Sempervivums, and these were in a most flourishing state. *Sempervivum arachnoideum* and *Laggeri* were grown as I have seen the former over the Mauvais Pas at Chamounix—literally on the stone itself, without apparently any earth at all, and in this way it flourishes. Great wisdom has been shown in selecting such plants as would be most likely to stand the smoke and at the same time look well. I have seen many much more pretentious rockeries which did not display half the taste, and it is only another instance of the truth of the adage that where there is a will there is a way. Many would have scoffed at the idea of having a rockery in such a place; but Mr. Wilson has admirably carried out his plans. I may say that he is also an enthusiastic grower of Auriculas, and that in his frames I saw many fine plants of the hybrid varieties. Lancashire Hero, George Lightbody, Conservative, Sylvia, Acme, Smiling Beauty, were all well represented. In his greenhouse, too, there was a fine lot of Geraniums, Begonias, &c. These are by the way. The great merit of the garden is the rockery, which I hope long may flourish.—D., Deal.

CANKER IN FRUIT TREES.

MR. HIAM does not appear to have hit upon a very happy idea in order to refute my theory of the cause of canker-infested fruit trees, nor in getting "Entomologist" to contradict his former opinion. If Mr. Hiam will refer once again to the wood culture as fruit culture he may be reminded that the art of cultivation first begins with the necessary preparations for the roots. Probably many besides Mr. Hiam overlook this most laborious branch of cultivation. I venture to think that if more attention was paid to it much less of other labour would be needed, not only in scraping and dressing cankered trees, but also pruning in general. Whenever I visit a garden during the summer, autumn, or early winter there is one cardinal point I keep in view. It is this. When I see bush or wall fruit trees allowed to grow and retain gross shoots sometimes over 3 feet long I conclude that the man in charge is not a good cultivator, to say nothing of the unsightly appearance, especially of wall trees, which having long ago covered their allotted space look more like hedges. It is often such neglected instances as those where old shreds or where fastenings are allowed to remain too long, and also like the ligatures referred to, rupture the bark and cause what may be regarded as canker, or what is equally injurious. I wonder how many flower sticks Mr. Haycock and some others who contribute so well to an Apple or Pear congress have to prune away from their celebrated trees at the present time.

Reverting to the main question of canker as showing that constitution has much to do with the disease, we may take an instance from the old Keswick Codlin and Lord Suffield Apple. Why is it that the former is so free from disease, whereas Lord Suffield requires the best treatment in order to keep it healthy? yet it can be so kept, and that without either scraping or other dressing. Of course in some localities less care is needed than in others in hot gravelly subsoils and in wet clayey subsoils. However, the roots must be first attended to. It will also be remembered that the severe and prolonged frosts a few winters past caused much canker in some kinds, especially with regard to Lord Suffield, doubtless owing to want of root-action. During the same winters many evergreens were killed or severely injured where the roots were in sterile ground. Where there is a good flow of sap there is also a certain amount of warmth. Hence, as well prepared ground is richer and more porous than unprepared, and consequently warmer, there is more chance of the trees resisting stagnation during such severe winters; neither do they suffer so much from drought during hot seasons.

Mr. Hiam must not take it that I hold there is no antidote against canker without lifting and transplanting, although I hold that nothing is so complete, and it is well sometimes to encourage a few roots for a season or two before lifting the tree. If Mr. Hiam has a goodly number of trees he will certainly have room for experiment, and assuming his borders are well drained our friend will find that several good supplies of liquid manure during the winter with a liberal mulching will work a considerable change in his trees during next summer. We have several trees treated as an experiment, which are now casting the once cankered bark, and clean healthy bark is fast covering the sore.

I confess I am behind my opponent in entomological matters. I have at times magnified a few of our common pests, but each time has only tended to strengthen me in my desire to have as little acquaintance as possible with them. It seems to me Mr. Hiam lays over-much stress upon the fact of having noticed so many insects beneath the dead bark of

his trees. If he will examine a strip of dead bark upon any old post and rail-fencing, or upon any partially dead branch, if a forest or fruit tree, there will also be insects in abundance at one season or another. But our scientific friend, "Entomologist," himself does not attach much practical value to research in these matters so far as argument goes. Hybridisers who are in search of new varieties are equally diligent to improve the constitution also, especially in common crops, such as Peas and Potatoes.—LATHYRUS.

ROYAL HORTICULTURAL SOCIETY.

NOVEMBER 10TH.

THE first meeting of the Committees after the close of the Inventions Exhibition was not an important one, the duties of both Committees were light and few meritorious novelties were exhibited.

FRUIT COMMITTEE.—T. F. Rivers, Esq., in the chair. Dr. Pritchard of Green Street, Sittingbourne, sent an Apple named St. Christopher, a conical fruit of excellent flavour. Mr. Joseph A. Nohle of Fortis Green sent a seedling Apple, which was not possessed of any merit. Messrs. Harrison and Sons of Leicester sent a seedling Apple of good size and symmetrical shape, resembling in form the Blenheim Pippin. It had a nice tender flesh and pleasant acidity, and was considered a good cooking Apple. Mr. Miller, The Gardens, Rood Ashton, Trowbridge, sent a large seedling kitchen Apple, which was passed. Mr. Lancaster, Holkham Gardens, Norfolk, sent excellent specimens of Gansel's Bergamot, Beurré Bosc, and Brown Beurré, to which a letter of thanks was awarded. Mr. B. S. Williams of Holloway sent fruit of Winter King Grape, but it was not in condition to be favourably judged. Rev. H. H. D'Ombraïn, Westwell Vicarage, showed good specimens of the White Plume Celery. A letter of thanks was awarded. Messrs. Rivers and Son of Sawbridgeworth sent a seedling Pear called Parrot. It was raised from Gansel's Late Bergamot, and is of the same round shape with a bright colour like Beurré Capiaumont. It was considered to be a useful market Pear for this season.

FLORAL COMMITTEE.—Three groups were contributed, for which silver-gilt medals being awarded, that from Mr. W. Bull, Chelsea, consisting chiefly of Orchids and new plants. Amongst the Orchids were plants of the free-flowering *Oncidium ornithorhynchum*, the bright yellow *Oncidium tigrinum*, *Lælia autumnalis atrovirens* with numerous crimson-tinted blooms, *Cattleya aurea*, *Odontoglossum Insleayi Leopoldi*, a large-flowered variety, the sepals and petals heavily barred with brown; *Vanda cærulea*, the fragrant *Trichosma suavis*, the fine plant of *Vanda Sanderiana* recently noted in these columns, the yellow *Oncidium concolor*, several pretty *Barkerias*, and a plant of *Mormodes pardina unicolor*, with bright yellow blooms on a close spike. Messrs. J. Veitch & Sons, Chelsea, had a pretty group of single and double *Bouvardias*; Sang Lorraine, and Thomas Meehan double red, Alfred Verner double white were the best of the latter, while of the single varieties *Priory Beauty*, *Umhellata carnea*, *Dazzler*, *Elegans*, and *Maiden's Blush*, which we have previously described, were the leading forms. A collection of well-grown *Cyclamens* was sent from the same nursery, together with blooms of new *Chrysanthemums*, for one of which a certificate was awarded. A Japanese variety named *Phoenix*, with large bright yellow blooms, was noteworthy, as also was the brilliantly coloured reflexed *Cullingfordi*. The third medal was awarded to Messrs. H. Page and Son, Teddington, for a group of over 200 *Cyclamens*, compact healthy plants, bearing a great number of flowers both light and dark coloured. They were fine examples of the best culture, and the honour awarded was well deserved.

A cultural commendation was adjudged to Dr. Duke, The Glen, Lewis-ham, for a basket of *Barkerias* in excellent condition and flowering most profusely. A similar recognition was accorded a specimen of *Gymnogramma schizophylla superba* from Mr. Wright, gardener to J. A. Whittard, Esq., Rydel Mount, Streatham, which was recently much admired at the Brixton Show. The plant was over 4 feet in diameter, with large graceful fronds, such as are rarely seen on this Fern as generally grown. Mr. R. Owen, Maidenhead, was awarded a vote of thanks for cut blooms of single *Dahlias* and *Chrysanthemums*; and Colonel T. Clarke, Daventry, had a similar recognition for a plant of *Ponrretia flexilis*, with long narrow recurving leaves, bright red at the base.

First-class certificates were awarded for the following plants:—

Chrysanthemum Mons. A. Vilmorin (J. Veitch & Sons).—A Japanese variety, with blooms of medium size, the florets fluted and recurved, orange red, yellow on the reverse side.

Amaryllis Autumn Charm (J. Veitch & Sons).—One of the reticulata type, with large beautifully formed blooms, veined with bright rosy pink, and having a clearly defined bar of white in the centre of each lobe.

Chrysanthemum Maiden's Blush (G. Stevens, Putney).—A large-flowered Japanese variety, with flat florets, white, or creamy, very full and handsome.

Cypripedium insigne Wallacei (New Plant and Bulb Company).—A distinct variety, the dorsal sepal clearly margined with white and heavily spotted with dark brown.

JAPANESE ANEMONE CHRYSANTHEMUMS.

LAST year we gave an illustration of the remarkably distinct variety *Fabian de Médiana*, then hearing the incorrect title *Fabias de Maderanaz*, and now we give another example (fig. 65) of this beautiful section of *Chrysanthemum*, *Sœur Dorothée Souille*. This differs considerably from *Fabian de Médiana* in the central tubular florets being much longer, and in the outer ray or guard florets being shorter and approaching more nearly to the character of the ordinary large-flowered *Anemone* varieties. The colour is a soft pink or blush, becoming nearly white sometimes, the outer florets being of a deeper tint. It makes a grand exhibition variety, and has this year assumed its true characters much earlier than *Fabian*

though the latter variety was in good condition quite as soon last season. Madame Cabrol, Madame Berthie Pigmy, and Margaret Vallageoise are also large-flowered varieties now included in this section, but at present they

classes; but there was a general opinion that the judges were too severe in disqualifying a stand of large-flowered Anemones at the Crystal Palace Show for containing blooms of Emperor, which has hitherto been admis-

FIG. 65.—CHRYSANTHEMUM SŒUR DOROTHEE SOUILLE.

ave not been so well shown as the two others. The committees of several Chrysanthemum societies have acted wisely in providing separate classes for these, and excluding them from the large-flowered Anemone

sible in that section, but however that may be, Sœur Dorothee Souille differs very widely from it, and is one of the most distinct and beautiful of large Japanese Anemone Chrysanthemums. The figure is an exact

representation of a bloom that was sent to us by an excellent cultivator of these flowers.

AUTUMN AND CHRISTMAS ROSES.

WE have to-day (November 6th) gathered a large bunch of good Roses, including Dupuy Jamain (almost up to exhibition form), A. K. Williams, Charles Lefebvre, La France, Marquise de Castellane, Souvenir d'un Ami, Marie Van Houtte, Anna Ollivier, Rubens, Princess of Wales, Madame Charles, and others, and on coming to one of our Hellebores in a sheltered position with a west aspect, were surprised to see some fine flowers peeping out. This led to further investigation of our other plants, and we found the whole of these pushing out their buds strongly, and enough flowers fully out to make quite a show by the side of the other Roses.

Is not this an unusually early date for Hellebores to flower in the open ground and on a cold soil? They are the common white variety, and have had no protection or assistance whatever, and in all other respects the autumn has not been a growing one, as observed by "D., Deal," on page 405. We propose planting some later sorts, and shall be glad of any information as to the best varieties.—NORTH HERTS.

NOTES UPON DAFFODILS AND NARCISSI.

(Continued from page 366.)

GROUP 1.—THE TRUMPET OR AJAX SECTION.

N. BICOLOR.—A fine Pyrenean Daffodil, with large spreading pure white perianth and large golden yellow trumpet; a form named *breviflos* is often distributed for it, but is much inferior and cheaper, and does not flower at the same time. The typical form now mentioned comes in about a fortnight later than the well-known variety *Horsefieldi*. There are several varieties of this which I will mention in the order in which they blossom—*Horsefieldi*, the earliest, with large white perianth, and dilated long golden yellow trumpet, raised by the late John Horsefield of Whitfield, near Manchester, one of the finest, and followed by *Empress*, which resembles *Horsefieldi* very much, but is a stronger grower; there is not, however, quite so much substance in the flowers. *Major* is in its prime at the same time as the type, and has a long rather narrow trumpet, very distinct and beautiful; *maximus* follows closely, and is much larger than the last, and most conspicuous, while the list closes with *Michael Foster*, or *sulphureus*, as it was formerly called, which produces immense flowers with pale sulphur perianth and deep yellow trumpet with very broad glaucous foliage.

N. BULBOCODIUM (the Hoop Petticoat Daffodil).—Easily known by its narrow-pointed perianth divisions and large crinoline-like trumpet of the richest yellow, is most charming for pot culture or the borders, preferring a moderately stiff soil and plenty of manure. The variety *citrinus*, with pale sulphur flowers, is extremely pretty and well worth growing, as also is the white form *monophyllus*, if a small handlight or frame can be devoted to it, otherwise it will not thrive satisfactorily, for being a native of Algeria it is too tender to grow unprotected outside.

N. LORIFOLIUS EMPEROR.—A magnificent variety, with pale sulphur divisions and very large deep yellow trumpet, and well merits its august name. As a companion to *Empress* it is most desirable. It was raised by a grower named Backhouse in Yorkshire, and was for a long time kept from commerce, and even now it is very uncommon.

N. MAJOR.—This should be grown everywhere, as it is cheap and very showy, rich yellow throughout, the perianth divisions being rather paler than the trumpet. It grows freely, especially in a warm situation, and is very variable. There are many forms, of which the following may be noted—*Maximus*, a noble form, producing very large trumpets with broad spreading limbs of the richest golden colour, and should certainly find a place in every collection. *Obvallaris*, the Tenby Daffodil, is also most desirable, perfect in form, bright golden yellow; the first of the large Trumpets to expand, standing uninjured during the severely rough weather we often get in March. *Spurius* is also a free early variety, while a form of it known as *coronatus*, also as *General Gordon*, is magnificent; the trumpet is very broad, at once a distinguishing feature, rich yellow, the spreading divisions much paler; it is comparatively scarce yet, but should certainly be secured.

N. MOSCHATUS, OR "SILVER TRUMPET."—The type of a very beautiful series of Daffodils which are well worthy being made a speciality, as they are so chaste and yet so hardy; the type is scarce. *Albicans*, usually vended as *moschatus*, is a robust grower with white divisions and large fringed pale primrose trumpet, very fine indeed. *Cernuus* is dwarfier, producing nodding flowers, with pale primrose trumpet and silver-white perianth divisions. *Cernuus pulcher* is similar, but the trumpet

is much longer, forming a most elegant flower. Of the hybrids belonging to this class mention may be made of William Goldring, Exquisite, Mr. Cowan, F. W. Burbidge, Mrs. F. W. Burbidge, and Dr. Hogg, all of which are extremely handsome. The two first are the most abundant, but as yet they are comparatively dear, but such gems should be secured if possible. I have everyone of those named, and nothing in my garden has given more pleasure this season. Mr. Cowan is very distinct, as the trumpet is very broad and short, pale primrose.

N. PSEUDO-NARCISSUS (the wild Daffodil).—I will only refer to the type as being useful for massing in woodlands, grass, &c., but there are several distinct and good forms which should be grown everywhere, and which are usually catalogued as distinct species. There is *pallidus præcox* (named thus by old John Parkinson) a very early-flowering Pyrenean form, with slightly drooping flowers of a pale sulphur colour throughout, the trumpet wide at the mouth. It is the first of all the Trumpet section to blossom, and should be sought. *Princeps* is very lovely, with a strong foothold in Ireland, varying considerably in form, size, and perianth colour; usually the latter is sulphur, and the trumpet deep golden yellow, sometimes very large, resembling *maximus*; hence Mr. Baylor Hartland of Cork has made a selection with rich yellow perianth, which he calls golden princeps, a most beautiful form. *Pallidus* produces creamy-white, sharp-pointed perianth divisions and brown trumpets very curly and delicate-looking, but in a well-drained position it does well; it comes from Spain.—J. T. R.

(To be continued.)

AUTUMN SHOWS.

EXHIBITORS of Chrysanthemums will soon be actively engaged in preparing for the numerous shows announced for the present season, and the following list of fixtures may be useful as a reminder. Secretaries of Societies not mentioned will oblige by forwarding their schedules.

November.	11th and 12th.	National Chrysanthemum Society, Croydon, Bath, and Ascot.
"	12th.	Walton-on-Thames, Staines, and Teddington.
"	12th and 13th.	Lindfield, Portsmouth, and Tunbridge Wells.
"	13th.	Reading.
"	13th and 14th.	Huddersfield, Cheshunt, and Exeter.
"	14th.	Ramsbottom.
"	17th.	East Grinstead, Yeovil, and Devizes.
"	17th and 18th.	Lincoln, Manchester, and Winchester.
"	18th and 19th.	Northampton, Bristol, Burton-on-Trent, and Birmingham.
"	19th.	Taunton, Hammersmith, and Aylesbury.
"	19th and 20th.	Hull.
"	20th and 21st.	Sheffield.
"	24th.	Liverpool.

FLOWERING PLANTS FOR THE STOVE.

MANY beautiful flowering plants were cast on one side only a few years ago to make room for fine-foliage plants which were then so popular. Happily taste has changed, and useful flowering plants are now eagerly sought for, but I fear some old favourites will be a long time before they again find a place in gardens generally. This is largely due to the enormous quantity of choice flowers that are now required, therefore only profuse flowerers with a minimum of labour really come to the front. These notes are not intended to deal exclusively with plants that fulfil the requirements of the present time, but those named are worthy of a place in any garden however limited the collection.

STEPHANOTIS.

I should have thought that the old *Stephanotis floribunda* would have been the last plant that would have been condemned. *Eucharis* and *Gardenias* are great favourites, but I think the flowers of the *Stephanotis* are superior, especially if the length of time the flowers last in water is considered. The continuous flowering habit of the plant over a period of many months alone places it in the foremost position. Some contend that there are two varieties of this plant, one profuse-flowering, and the other shy; this may be the case, but experience and observation seem to point to the contrary. I have two plants, one supposed to be the free-flowering sort, and the other the opposite. The past two years they have reversed their characters, and the last-named is now the free-flowerer, while the former has scarcely produced any flowers. This is by no means due to the varieties, but to the different positions the two plants occupy. The so-called free-flowering variety is growing in a shady portion of the house, while the other occupies a much lighter and more open position.

A striking case came under my observation only a few years ago when practising further north. We had a plant in the fernery well exposed to light, air, and only an intermediate temperature. Often during the winter the portion of the house in which it grew was not much warmer than an ordinary greenhouse. I do not remember seeing a plant that produced the same quantity of flowers. A cutting was struck from this plant and placed in the stove, but it only produced solitary trusses of bloom. The very same state of things I have observed in other gardens, hence the general opinion that there are two varieties.

Frequently plants of *Stephanotis* are to be found trained under the roof of an ordinary plant stove where a mixed collection of plants is grown, and the conditions of such a house are generally unsuited to flowering the plant profusely. It grows luxuriantly enough in a close moist shaded structure, such as the one indicated above, and that is all that can be said. The secret of growing and flowering this plant well is

to have it exposed to full light and sunshine, shade being unnecessary is plenty of air is given during bright weather. A little shade, however, would really prove no detriment while the plant is growing rapidly, provided it only broke the sun's rays and was applied for a few hours during the hottest part of the day. Plenty of heat and moisture while the plant is growing is an advantage if abundance of light is given and air freely admitted to harden and solidify the wood. This treatment results in short-jointed wood and trusses of bloom from every joint.

At this season of the year the wood should be thoroughly ripened or brought into that condition as early as possible. A good season of complete rest is essential to the plant if plenty of flowers is expected another year. During this important period the wood should be exposed to every ray of light in a moderately dry atmosphere, and in a temperature that does not exceed 55° at night, 5° lower is preferable to a higher temperature during cold weather. While in this condition no more water should be given at its roots than is sufficient to keep the growth and foliage fresh and plump. Under these conditions this plant will rest completely, which it will not do in the close, moist, and warm atmosphere of the stove. I am inclined to believe that if this simple treatment were more generally followed we should hear less of two varieties.

GARDENIA CITRINODORA.

This was a general favourite amongst stove plants some years ago before the varieties of *G. florida* were so extensively grown as they are at the present time. It has gone like many other good old plants, and now is rarely seen. It is, however, no less beautiful than formerly, and its sprays of Orange-like fragrant flowers that are produced freely from the axils of the leaves during winter should commend it to the public. Small shapely plants can be grown suitable for single vases more readily than the double forms, but even for the embellishment of the stove alone it is well worth attention. It grows freely under good cultivation, and very soon makes bushy little flowering plants in 5-inch pots. The main secret of success is to select clean healthy cuttings, and then grow them on afterwards without a check. Strong non-flowering shoots rooted in July and wintered in small pots will be bushy plants by spring, and ready for transferring into the pots in which they are to flower. It is necessary to grow the young plants under the influence of light, plenty of heat, and moisture, and then every shoot will flower. Careful watering is needed until plants are rooting freely into the soil, for if they once become checked they seldom do much good. It is also important that thrips and scale, which appear to be very fond of this old plant, are never allowed to become established, or they will not only destroy the foliage, but bring growth to a complete standstill. If the plants are kept growing in a moist structure and liberally syringed, insects will not infest it any sooner than other stove plants.

MEDINILLA MAGNIFICA.

A few years ago *Medinilla magnifica* was decidedly more popular than it is now, and it seems a pity that such beautiful ornamental plants should not be more largely grown at the present time. It is true it is not suitable for yielding abundance of flowers for cutting, but when its large pendulous racemes of rosy pink flowers are produced few stove plants can surpass it for beauty. The flowers last a long time in perfection, especially if the plant is stood while in flower in a rather dry moderately cool atmosphere. It generally flowers during April and May, but can be retarded or brought into flower earlier, as the flowers are produced from the termination of the shoots of thoroughly ripened wood. This is a free-growing plant, but does not flower freely under ordinary stove treatment, and this may in some measure account for it not being more generally grown. Even when this plant is not in flower it is ornamental.

While growing stove treatment should be given; in fact, a house where a mixed collection of plants is grown will suit it very well, provided the lightest position is selected for it. If the plant is to flower light must be freely admitted to ripen and harden the wood, especially during the last stages of development; in fact, light must be gradually admitted to it until it will bear full exposure to the sun. During the latter stages of ripening a cooler and drier atmosphere should be maintained until the wood is hard and ripe. It should then be rested in an intermediate temperature, where a moderate amount of air is admitted and the atmosphere is kept comparatively dry. No more water should be given than is sufficient to keep the foliage and roots healthy. Whether the plants flower well or not entirely depends upon the treatment they receive, and those who possess plants should be careful what treatment they receive from the present time, for the wood must be thoroughly ripened and then given a rather lengthened period of rest. During the season of inactivity a strict watch should be kept for thrips, for they are very liable to attack the plant during the time growth is at a standstill. Mealy bug will infest it, but the first-mentioned insect if once established very soon destroys its large deep green leathery foliage.

ANTHURIUM ANDREANUM.

At one time I was rather inclined to condemn *Anthurium Andreanum*, for I failed to see what qualities it possessed to merit recommendation. In spite of my first impressions I now regard it as a very valuable addition to our stove-flowering plants, for it is strikingly ornamental. It is rarely without one or more spathes. There are several varieties, and certainly some of them are not worth house room, but good varieties with brilliantly coloured spathes 7 or 8 inches in length and almost 6 inches wide, cannot be despised; fortunately I possess one of the finest varieties I have yet seen. One of the worst features of this plant is its natural habit of running up quickly with a slender stem, and thus it soon becomes unsightly unless the lower portion is hidden by surrounding plants. This

can be remedied, however, by a little care and patience, for the plant can be topped, and will root again as freely as the old *Alocasia metallica*. It roots quickly if placed in a pot, or it can be mossed round the stem for a few weeks previous to being taken off, and if this is done and a few roots established in the moss the plant commences growth at once. The stem will break into growth again as freely as the plant above alluded to, and therefore when this is generally known we may expect to see large panfuls grown on the same principle as we are accustomed to see *Alocasias* now. It appears to break freely from nearly every joint of the stem, but whether it will propagate freely from the stem cut into lengths I do not know, for I have not yet had the opportunity of testing it, but intend doing so in the spring. If this is the case imported seedlings can be dispensed with, for they often yield many worthless varieties.—WM. BARDNEY.

ZINC LABELS FOR OUTDOORS.

The following sketch will illustrate what I think a better way of fixing zinc labels for outdoor use than that suggested by your correspondent, Mr. Walter Kruse, on page 380. Holes are pierced in the stem of the label, and the wire passed through them as shown in the figure. The top end of the wire is beaten flat, and the pointed piece standing up in the centre of the label pressed down over it. This allows the label to be passed into the ground, and prevents it turning round with the wind. The wire should be about a foot long, and be passed into the ground till the base of the label just enters the surface. I used those for Roses last year, and think they answer the purpose well. They are neat, not conspicuous, and present the writing in the most convenient position to the eye; and as your correspondent says, when the name gets illegible they have only to be cleaned and re-written to be as good as new.—R. INGLIS.

Fig. 66.

For those who do not wish for such an elaborate-shaped label a plain one is recommended, as it can be cut out quickly, because one cut helps to form two labels, and also because straight lines are much easier to cut than curved. Each label is half a hexagon, and consequently there is no waste of zinc, unless a small piece at the ends of each alternate line (which, however, can be formed into a smaller triangular-shaped label). This arrangement reminds me of the hexagonal cells of honeycomb, which

Fig. 67.

as is well known, is a model of economy of space and strength. The labels are cut out more quickly when two rows are marked on the sheet at a time, and the slip cut off. If the end label is always cut off as delineated it is obvious that the "snips" will not have to turn any corners, which takes up time and necessitates bending the zinc. The labels can be made of any required size.—W. KRUSE.

CHRYSANTHEMUM SHOWS.

RICHMOND.—NOVEMBER 5TH AND 6TH.

FIVE autumn exhibitions have now been held by the Richmond Horticultural Society, and that which took place on Thursday and Friday last will bear comparison with any of the preceding ones, for though perhaps less extensive than some, it was equal to the best in quality. The Committee, with the courteous Secretary, Mr. J. Ford, have worked most perseveringly to render their Chrysanthemum shows successful, but hitherto, though quite satisfactory horticulturally, there have been some disagreeable financial deficits that rather seriously decreased the balance obtained from the summer shows. It is to be hoped, therefore, that the result this year will be more favourable in this respect, and that the autumn exhibition may become as firmly established as the annual show in the Old Deer Park. The Assembly Rooms, Castle Hotel, were again chosen for the Exhibition, which was visited during the afternoon of the first day by Princess Mary and the Duke of Teck, attended by a number of friends.

Cut blooms formed the leading feature of the Show, and were generally very even and good, so that in several of the principal classes the Judges had a difficult task in making the awards. The Society, with a spirited liberality, had provided a class for forty-eight blooms, twenty-four incurved and twenty-four Japanese, the prizes being £10, £6, and £4, and though this did not induce so many competitors to enter as might have been expected, yet the blooms staged were of excellent quality and were greatly admired. Five collections were staged, Mr. C. Gibson, gardener to J. Wormald, Esq., Morden Park, Mitcham, being the winner of the substantial first prize with handsome solid blooms of the following varieties, reading their names from left to right as they were in the stands. Incurved—back row—Queen of England, Prince Alfred, Empress of India, Refulgence, Lord Alcester, Lord Wolseley, Princess of Wales, and Alfred Salter. Second row—Yellow Perfection, White Beverley, John Salter, Novelty, Princess Beatrice, White Venus, Mr. Bunn, and Beethoven. Front row—Lady Hardinge, Prince of Wales, Mrs. Dixon, Mrs. Rundle, Mrs. Shipman,

Venus, Golden Eagle, and Mr. G. Glenn. All these were admirable representatives of their varieties, and some were exceptionally fine. Japanese—back row—Madame Berthie Rendatler, Jeanne Delaux, Elaine, Criterion, Fernand Feral, Mons. Delaux, M. Tarin, and Mdlle. Lacroix. Second row—Comte de Germiny, Madame C. Audiguier, Mdlle. Moulise, Madame de Sviu, M. Astorg, Peter the Great, and Val d'Andorre. Front row—Cry Kang, Fanny Boucharat, Flamme de Punch, Comtesse de Beauregarde, M. Ardene, Fulgor, Ethel, and Magnum Bonum. These were remarkably fresh and rich in colour, though we doubt if Mr. Gibson has included his best blooms. The second prize was awarded to Mr. Sullivan, gardener to D. B. Chapman, Esq., Downshire House, Roehampton, for a praiseworthy collection of fine blooms, close in merit to those in the preceding stand. The incurved, though slightly smaller, were very neat, and the Japanese were of good substance, including some of the most effective exhibition varieties, together with a sport from Baronne de Prailly with irregularly cut florets of a yellow colour faintly edged with bronzy red. Mr. A. Elphick, gardener to J. Clutton, Esq., The Orchard, Reigate, was third with a creditable stand of blooms.

Mr. Sullivan had the best twenty-four incurved blooms, neat, compact, even blooms, Princess Beatrice, Mr. Shipman, Queen of England, and Mr. G. Glenn being notable varieties. Mr. J. Beuett, Feldheim Gardens, Wimbledon, following very closely with clean and beautiful blooms. The class for twelve incurved varieties brought some good samples, Mr. E. Combs, gardener to W. Furze, Esq., Teddington, gaining first honours for a highly satisfactory collection, comprising Queen of England, Golden Empress, Empress of India, Lord Alcester, Lord Wolseley, Prince of Wales, Alfred Salter, Prince Alfred, Jeanne d'Arc, Mr. Bunn, John Salter, and White Beverley. Mr. Elliott and Mr. Woodgate, gardeners to Lord Wolverton, Warren House, Combe Wood, followed in the order named, each showing well.

A class was devoted to twenty-four Japanese varieties, not less than eighteen varieties, and in this Mr. Bennett, Feldheim Gardens, took the lead with handsome substantial blooms of Madame C. Audiguier, Mdlle. Lacroix, Criterion, Val d'Andorre, Jeanne Delaux, Joseph Mahood, Flamme de Punch, M. Desbrieux, Henri Jacotot, amongst others nearly as fine. Mr. Woodgate was second, showing M. Burnett, M. John Laing, La Nympe, Criterion, Henri Jacotot, Mr. Townsend, and Madame de Sevin. The first place for twelve Japanese was adjudged to Mr. Benson, who had particularly notable examples of Madame Berthie Rendatler, Comte de Germiny, M. John Laing, Mdlle. Lacroix, Val d'Andorre, Soleil Levant, and Baronne de Prailly. Mr. Munro, Cambridge House Gardens, Twickenham, and Mr. Coombs were second and third respectively. Mr. Munro being first with six Japanese of one variety, with Madame C. Audiguier, large and substantial. Anemone varieties were well shown by Messrs. Sullivan and Bennett.

Plants were not so numerous, the groups of Chrysanthemums arranged for effect constituting the chief portion of the display. Mr. W. Champion gardener to T. Cave, Esq., Queensberry House, Richmond, secured first honours with a tasteful group of dwarf plants, the incurved blooms being very fine. Mr. Munro was second with taller plants, and rather more Japanese. Mr. J. Rooke, gardener to J. B. Hilditch, Esq., Asgill House, and Mr. Sallows, gardener to J. J. Flack, Esq., Twickenham, following, both with tall plants. The last named had the best six trained specimens, but the sticks were much too thick and prominent, except in Hiver Fleuri and L'île des Plaisirs, which were about 5 feet in diameter, and bearing over 100 blooms each. Mr. Elliot, gardener to Mrs. Harrison, Leydon House, Mortlake, was first with three standards, very evenly trained, and well clothed with foliage. Messrs. Hooper & Co., Covent Garden, contributed the most tasteful group of miscellaneous plants, Mr. W. Brown, Mr. G. Tilsell, and Mr. Chard following.

In the classes for fruit Mr. Bates, gardener to Mrs. Meek, Poulett Lodge, was the principal exhibitor, being first with six dishes of fruit in the Society's class, and for Lady Parker's prizes also; Messrs. Champion, Osman, and Munro securing the other awards. Mr. W. Champion was first in the black Grape class with Gros Colman, finely coloured. Mr. W. Howe, gardener to H. Tate, Esq., Streatham, was second with large bunches of Alicante; and Mr. Osman third with the same variety smaller. Mr. Bates led in the white Grape class with Muscat of Alexandria, very clean, even, large berries superbly coloured. Apples, Pears, vegetables, and stands of flowers, with several non-competing exhibits, such as the group of 150 Cyclamens from Messrs. Page & Son, with the tasteful bouquets and wreaths from Mrs. H. B. Smith, Ealing, added materially both to the extent and interest of the Show.

HAVANT.—NOVEMBER 5TH AND 6TH.

THIS Society held its second annual Exhibition of Chrysanthemums fruit, and vegetables at the Town Hall, Havant, on the 5th and 6th inst. The Show taken as a whole was a marked improvement upon that of last year, many of the cut blooms being remarkably fine. There was very strong competition in the vegetable classes, which occupied a spacious tent to themselves. The principal class for plants was for groups of Chrysanthemums to cover 40 feet. This space not putting too much pressure on the exhibitors enabled very pretty groups of good quality to be arranged, Messrs. White, Fuller, Moseley, and Kinchott taking the awards in order named. Several other classes for plants were well filled, especially those for cottagers. In the cut bloom classes the greatest competition was for twenty-four blooms, twelve incurved and twelve Japanese, distinct. Most of the stands contained some conspicuously good blooms; but Mr. Penfold, gardener to Sir F. Fitzwygram, Bart., M.P., Leigh Park, was a good first with the following:—Incurved—Golden and White Empress of India, Queen of England, Jeanne d'Arc, Lord Wolseley, Prince Alfred (grand), Mrs. W. Shipman, Lady Hardinge, Alfred Salter, Princess Imperial, Lady Carey (good), and Jardin des Plantes. Japanese—Oracle, Fernand Feral, Balmoreau, Elaine, Jeanne Delaux (extra fine), Fair Maid of Guernsey, Madame C. Audiguier, Mons. Ardene, Soleil Levant, Hiver Fleuri, Comte de Germiny, and Fanny Boucharat. Mr. W. White, gardener to J. E. Cox, Esq., came in second; and Mr. Roberts, gardener to E. R. Longcroft, Esq., third. Mr. Penfold also secured first honours for twelve Japanese, twelve incurved, twelve Anemones in six varieties, and for twelve blooms (four each) incurved, Japanese, and reflexed. The latter were all splendid blooms,

but we think a class of this description should exclude prizetakers in the larger classes and give a chance to smaller growers, who are unable to bring forward complete stands of any one class. Mr. Leng, jun., obtained first prize for a very beautiful stand of the Rundle family in couples, and Mr. Roberts was first in the reflexed class. Other successful exhibitors were Messrs. Fuller, Woodbine, Moseley, Kinchott, and the Rev. R. J. Wells.

CRYSTAL PALACE.—NOVEMBER 6TH AND 7TH.

THE Exhibition held at "the Palace" on Friday and Saturday last will be one of the most memorable of the season, if only for the remarkable successes scored by the noted cultivator, Mr. E. Molyneux, gardener to W. H. Myers, Esq., Swanmore Park, Bishop's Waltham, who secured no less than seven first prizes in close competition. One of these was a decided victory and something to be proud of—namely, the premier award in the class for forty-eight blooms (twenty-four incurved and twenty-four Japanese not less than eighteen varieties of each), which he won with a collection of extraordinary merit, the blooms generally extremely large and well proportioned, though a few of the incurved were too flat to satisfy such a critic as Mr. E. Sanderson. The Japanese were wonderfully fine in substance and colour, while several of the incurved, such as Alfred Salter and John Salter, were as near perfection in all points as could be imagined, two of the weakest blooms being Emily Dale and Jardin des Plantes. The varieties were as follows, naming them in the order as they were arranged from left to right. Incurved—back row—Queen of England, Lord Alcester, Queen of England, Alfred Salter, Empress of India, Alfred Salter, Lord Alcester, and Empress of India. Second row—Jeanne d'Arc, Princess of Wales, Emily Dale, Lord Wolseley, Princess of Wales, Emily Dale, John Salter, and Golden Empress. Front row—Empress Eugénie, Jardin des Plantes, Prince Alfred, Princess Beatrice, Refulgence, Lady Hardinge, Mr. Bunn, and Nil Desperandum. In the Japanese the very beautiful variety, Belle Pauline, which has long slightly recurved florets, white, edged with bright purple, was very attractive, the new Val d'Andorre being grandly represented both as regards size and colour. The varieties were as follows:—Back row—Madame C. Audiguier, Fair Maid of Guernsey, Belle Pauline, Val d'Andorre, Baronne de Prailly, Val d'Andorre, Meg Merrilees, and Madame C. Audiguier. Second row—Sceptre de Toulouse, Jean Delaux, Criterion, Madame Deyville, Meg Merrilees, Madame B. Rendatler, Belle Pauline, and Criterion. Front row—Boule d'Or, Mdlle. Lacroix, Margaret Marrouch, Elaine, Duchess of Albany, Madame de Sevin, Soleil Levant, and M. Astorg. Highly commendable blooms have been frequently shown by Mr. Molyneux, but we do not think he has surpassed this effort, considering the qualities of both incurved and Japanese. There were eleven other competitors, but none of them came within many points of the winning collection, though Mr. C. Gibson, gardener to J. Wormald, Esq., Morden Park, Metcham, was a good second, for his incurved, if not quite so large or well dressed, were even and of good proportions. The Japanese were the stronger blooms, such varieties as M. Boucharat, M. Astorg, Madame de Sevin, L'Incomparable, Margaret Marrouch, Jeanne Delaux, Criterion, Val d'Andorre, and Mdlle. Lacroix being capitally shown; while in the incurved were fine blooms of Lord Wolseley, Prince Alfred, Prince of Wales, Queen of England, and Refulgence. The other prizes were awarded to Messrs. W. & G. Drover, Fareham, Hants, and A. Holmes, gardener to A. B. Hill, Esq., South Road, Clapham Park.

The good blooms were not, however, confined to the great class; for in all the others the samples staged were much above the average, and the competition keen, so that none of the prizes were very easily gained. Mr. Molyneux repeated his success in the class for eighteen incurved varieties, staging beautiful blooms of Golden Empress, John Salter, Alfred Salter, Lord Alcester, Queen of England, Empress of India, Cherub, Empress Eugénie, Princess of Wales, Lord Wolseley, Emily Dale, Sir Stafford Carey, Mr. Bunn, Prince Alfred, Refulgence, Jeanne d'Arc, Jardin des Plantes, and Novelty. Mr. E. Berry, Roehampton House Gardens, was second (Lady Slade and Alfred Salter were the two best blooms), and Mr. J. Holmes, gardener to G. M. Storey, Esq., Nightingale Lane, was third with an even collection. Mr. Molyneux gained the principal award for six incurved varieties of one variety with excellent blooms of Alfred Salter, fresh, clean, and beautifully formed.

Japanese varieties were extremely fresh and substantial, the colours being exceedingly bright. Eight stands of eighteen varieties.—Mr. J. Ridout, gardener to T. B. Haywood, Esq., Woodhatch Lodge, Reigate, secured premier honours with charming examples of Dr. Macary, Japonaise, Jeanne Delaux, Fair Maid of Guernsey, Madame C. Audiguier, Chang, Comte de Germiny, The Daimio, Madame B. Rendatler, M. John Laing, Soleil Levant, M. Tarin, Red Gauntlet, Peter the Great, Madame Deyville, Criterion, Madame de Sevin, and Mdlle. Lacroix. The second and third prizes were gained by Mr. J. W. Springbelt, Cheshunt, who had M. Henri Jacotot very fine, and Mr. A. Berry, who staged a grand example of Criterion. Twelve stands of a dozen blooms were contributed, Mr. J. Brown, gardener to A. J. Waterlow, Esq., Great Doods, Reigate, taking the lead with Madame C. Audiguier, M. John Laing, Japonaise, Val d'Andorre, M. Astorg, Criterion, J. Delaux, Fanny Boucharat, Comte de Germiny, Pride of Reigate, Madame B. Rendatler, and Dr. Macary. In this class Mr. Molyneux had to be contented with second place, though he had some fine blooms of Belle Pauline, Val d'Andorre, Madame C. Audiguier, Elaine, and M. Astorg. Mr. J. Wyatt, gardener to J. Perry, Esq., Bradenhurst, Caterham Valley, was third with bright neat blooms. For six Japanese of one variety Mr. Molyneux was first with Madame C. Audiguier, six magnificent blooms about 7 inches in diameter and as much in depth. Mr. C. Orchard, gardener to J. Galsworthy, Esq., Coombe Warren, Kingston, was a very close second with M. Henri Jacotot of excellent substance and superb colour. Mr. G. Burnett, gardener to Mrs. Fenton, The Grange, Hillingdon, was third with Triomphe du Nord, considerably finer than it is usually seen.

Reflexed blooms were well represented, Mr. Molyneux leading with twelve, not less than eight varieties, and staged capital specimens of Mdlle. Madeleine Tezier, Golden Christine, King of the Crimson, Distinction, Dr. Sharpe, Felicity, Phidias, Cullingfordi, brilliant colour, and Pink Christine. Mr. T. Sadler, gardener to C. Lambert, Esq., Streatham, was second, also having Cullingfordi, very fine, with Cloth of Gold and Phidias; Mr. Chadwick being third with smaller blooms. The best twelve Anemones came

from Mr. E. S. Cole, Woodside Gardens, Snayd Park, Bristol, including the varieties Lady Margaret, Empress, Georges Sands, Gluck, Fleur de Marie, Prince of Anemones, Acquisition, and Margaret of Norway. Mr. T. J. Sadler and Mr. Chadwick were second and third, one stand being disqualified for containing blooms of Emperor, which was considered as a Japanese Anemone, though it has been frequently shown in stands of large Anemones. Mr. Molyneux took the lead with twelve Anemone Pompons, having bright blooms of Mr. Astie, Perle, Antonius, Margaret de Coi, Regulus, Madame Montels, Marie Stuart, and Miss Nightingale. Mr. Cole contributed the best six Japanese Anemones, showing two blooms each of Madame Brethie Pigmy, Sœur Dorothee Souille, and Madame Clos. Mrs. Springbett followed with Fabian de Mediana, Sœur Dorothee Souille, and Madame Clos. A beautiful collection of twelve Pompons from Mr. Molyneux gained the premier prize in the class. The varieties were Pygmalion, La Purété, President, Black Douglas, Eleonore, Golden Circle, Prince of Orange, Adele Prissette, Madame Marthe, Rose d'Amour, and Prince Victor.

Groups of Chrysanthemums constituted the principal portion of the display in the plant classes, the specimens not being very remarkable. In the amateurs' class for a group to occupy a space of 50 square feet Mr. C. Orchard easily won the premier honours with a very beautiful and tastefully arranged group of well-grown plants, bearing handsome blooms, both incurved and Japanese being admirable, while a suitable proportion of dwarf plants afforded an agreeable finish to the group. The handsome reflexed variety Cullingfordi was very good, as was also M. Henri Jacotot. Mr. W. Webster, gardener to Mrs. Croll, Mavis Bank, Grange Road, Upper Norwood, and Mr. C. S. Bowman, London Road, Croydon, were second and third, each putting up bright effective collections. Two classes were devoted to nurserymen's groups, one for incurved varieties and the other for Japanese, the principal prizes being secured by Mr. G. Stevens, Putney, and Messrs. J. Laing & Co., Forest Hill; followed by Messrs. J. Carter & Co., and G. Edwards, Balham. In the other plant classes the best specimens were shown by Messrs. E. Cherry, Weston, Portway, W. Clark, and Howes. First-class certificates were awarded for the following new varieties, a bronze sport from Queen of England, shown by Messrs. J. Carter & Co., being commended.

M. John Laing (J. Laing & Co.).—A Japanese variety, with blooms of excellent substance, the florets fluted, recurved, and of a dark bronze red; very distinct and effective.

Madame Laing (J. Laing & Co.).—A Japanese variety. The florets broad and flat, white, with a tinge of purple or blush. The blooms come of good size and are then very handsome.

KINGSTON-ON-THAMES—NOVEMBER 10TH AND 11TH.

THE ninth annual Show of the Kingston and Surbiton Chrysanthemum Society was held in the Drill Hall at Kingston on Tuesday and Wednesday, and, as usual with the exhibitions of this flourishing and well-managed organisation, was a great success. Several of the most renowned growers in the south of England were amongst the exhibitors, the competition was good in most of the classes, and the exhibits were well up to the average in point of quality. Great interest was vested in the competition for what may be described as the most important prize—namely, the challenge vase for forty-eight cut blooms, which must be won twice by one exhibitor. As many readers may remember, Mr. Molyneux, gardener to W. H. Myers, Esq., Swanmore Park, Bishop's Waltham, secured a previous cup with two consecutive wins, and he was also successful last year, so that a victory on the present occasion would insure the second cup finally passing into his possession. His old and able opponent, Mr. Gibson, gardener to J. Wormald, Esq., Morden Park, Mitcham, was, however, known to be showing remarkably well, and thus the result of the struggle between the two was watched with the keenest interest. The verdict was in favour of Mr. Molyneux, who has thus a splendid record of four consecutive victories, and the superiority of his blooms was even more marked on the present than on previous occasions. Details of results in this and other classes are as follows:—

CHALLENGE VASE.—For twenty-four Japanese and twenty-four incurved flowers, Mr. Molyneux was first with grand specimens of the following, the names being read from left to right:—Japanese, back row—Fair Maid of Guernsey, Sceptre Toulouse, Belle Pauline, Val d'Andorre, Criterion, Madame C. Audiguier, J. Delaux, and Baron de Prailly. Middle row—M. Ardenne, Soleil Levant, Madame B. Rendatler, Balmoreau, Meg Merrilies, Boule d'Or, Dormillior, and Duchess of Albany. Front row—Mlle. Lacroix, Margaret Marrouch, Mons. Burnet, Golden Dragon, Madame de Sevin, Elaine, John Laing, and Album Plenum. Incurved, back row—Lord Alcester (a very fine bloom), Princess of Wales, Emily Dale, Alfred Salter, Golden Empress, Mrs. Howe, Empress of India, and Queen of England. Middle row—Lord Wolsley, Jardin des Plantes, Prince Alfred, Princess of Teck, Hero of Stoke Newington, Jeanne d'Arc, Empress Eugénie, and Sir Stafford Carey. Front row—Lady Harlinge, Nil Desperandum, Eve, Lady Carey, Mr. Bunn, Rev. J. Dix, Barbara, and Mrs. Heale. The blooms were remarkable both for size and symmetry, and also for "finish," for which Mr. Molyneux's flowers are famous. Mr. Gibson was second, showing Japanese varieties exceptionally well, and with incurved flowers as good as, if not better than, he has shown before here. Mr. E. Coombs, gardener to W. Furze, Esq., Teddington, was a very fair third; and Mr. Rogers, gardener to C. S. Wilde, Esq., Cheam House, Cheam, fourth. Two other collections were shown. It may be said that the Japanese blooms in the stands of Messrs. Molyneux and Gibson were about even in point of merit, but the Swanmore incurved flowers were far in advance of those from Morden Park, while those in turn were distinctly ahead of the Teddington blooms.

CUT BLOOMS.—Incurved.—The chief class was that for twenty-four flowers, and Mr. Molyneux again won easily, showing the same varieties as those already named, and including some very fine specimens. Mr. G. Woodgate, gardener to Lord Wolverton, Warren House, Kingston, was second, showing much smaller but wonderfully neat blooms. Mr. Coombs was third, and Messrs. W. & G. Drover, nurserymen, Fareham, fourth. One other stand was in competition. For twelve blooms Mr. A. Carter, gardener to Alderman and Sheriff Evans, Ewell Grove, Ewell, was first; Mr. G. King, gardener to R. Few, Esq., Wolsey Grange, Esher, second; and Mr. Watson, gardener to Captain Cundy, Southborough Park, third. Three other stands were shown. For six blooms Mr. Benson secured the first

prize very easily, showing Empress of India, Queen of England, Golden Empress, Lord Alcester, Hero of Stoke Newington, and Lord Wolsley, all good. Mr. Slade was second. The class for six blooms of one variety found Mr. Molyneux again to the fore with fine specimens of Princess of Wales, this being the fourth time consecutively he has won the prize in this class with the same variety. Mr. Benson was second with good blooms, and Mr. King third. Ten collections of six were staged by previous non-prize-winners. Mr. Trussler, gardener to J. Shand, Esq., Fullbrooks, Old Malden, being first; Mr. Holden, gardener to Mrs. Izod, Esher, second; and Mr. F. Cawte, gardener to D. Braud, Esq., Ashdown Lodge, Walton, third.

Japanese—twenty-four blooms.—First, Mr. Molyneux; second, Mr. King; third, Mr. Woodgate; fourth, Mr. Munro, Cambridge House Twickenham. The first-prize flowers were excellent, but it was evident that the exhibitor had thrown his strength into the cup class. Five stands were staged in all. Five were also in competition with twelve blooms, the first prize going to Mr. A. Carter, the second to Messrs. Drover, and the third to Mr. Holden. Both first and second were fairly good. For six blooms Mr. Benson, gardener to W. H. Roots, Esq., Caubury House, Kingston, was first with excellent flowers of Mlle. Lacroix, Boule d'Or, M. Farren, Val d'Andorre, Meg Merrilies, and The Sultan. Mr. Slade, gardener to Lady Bowater, Richmond Park, was second; and Mr. Read, Broadwater House Gardens, Otlands Park, third. For six blooms of one variety only Mr. Molyneux was an easy first with magnificent specimens of Belle Pauline, Mr. Slade was placed second with Madame Audiguier, and Mr. King third with Mlle. Lacroix. Two others exhibited. No less than eleven entered in the class provided for those who had not previously won a prize. Mr. Glover, gardener to W. Evill, Esq., Worcester Court, Worcester Park, was first, Mr. F. Cawte second, and Mr. Rosier, Gordon House, Ham Common, third.

For twelve reflexed flowers, Mr. Molyneux was again first, showing beautiful specimens of:—Back row—Mlle. Madeline Tezier (2), Golden Christine, and Cloth of Gold. Middle row—Distinction, Dr. Sharpe, Golden Christie, and Cloth of Gold. Front row—Phidias, Cullingfordi (2), and Pink Christie. The second prize went to Mr. Coombs, and the third to Mr. Slade.

Twelve Anemone-flowered:—First Mr. Gibson with the following:—Back row—Lady Margaret (2, splendid flowers), Gluck, and Acquisition. Middle row—Mrs. Pithers, Georges Sand, Gluck, and Prince of Anemones. Front row—Fleur de Marie, Prince of Anemones, Madame Goderau, and Georges Sand. The second prize was awarded to Mr. Slade, and the third to Mr. Molyneux. The last-named exhibitor showed Japanese Anemone-flowered varieties splendidly, and was awarded the first prize. His stand was composed of the following varieties:—Fabian de Mediana, Sœur Dorothee Souille, Mlle. Cabrol, and Margaret Villageoise. Mr. Benson was first for twelve bunches of Anemone Pompons, the following varieties being shown:—Astrea, Grace Darling, Mabel, Miss Nightingale, Antonius, Jeanne Hatched, Marguerite de Coi, and Firefly. Mr. Molyneux was placed second.

GROUPS.—For the best collection of Chrysanthemums in pots, Mr. J. Buss, gardener to A. S. Price, Esq., Parkside House, Ewell, secured the premier prize. Sturdy, healthy plants, with flowers of good size and admirably arranged, gained him the award. Mr. Glover was placed second, and Mr. Moorman, gardener to Miss Christy, Coombe Bank, Kingston Hill, third. All these groups were of great excellence, the dwarf plants of Val d'Andorre and others less than 2 feet high with splendid foliage and blooms, in the first-prize arrangement, attracting much attention.

For six dwarf-trained incurved specimens with single stems Mr. King was first with Mr. G. Glenny, Prince of Wales, Mrs. Geo. Rundle, Mrs. Dixon, Barbara, and Golden Empress, the three first-named being very fine plants. Mr. H. Trussler was a very close second. Mr. Sallows, gardener to J. J. Flack, Esq., Hampton Road, Twickenham, was adjudged the first prize for three plants, showing Prince Alfred, Mrs. Dixon, and Mr. G. Glenny. No others competed. Mr. King was first with Mrs. George Rundle for a single specimen, and Mr. Sallows second with the same variety. Mr. Elliott, gardener to Mrs. Harrison, Leyton House, Mortlake, was to the fore with three standards, the varieties being Mr. Geo. Glenny, Mrs. G. Rundle, and Mrs. Dixon, beautifully trained specimens. Mr. Trussler was second with excellent plants, and Mr. Sallows third.

For three trained Japanese Mr. G. King took first prize, showing grandly flowered plants of Bouquet Fait, Safranum, and La Nympe. Mr. Sallows received the second prize, and Mr. Trussler the third. The two last-named exhibitors were first and second respectively for a single plant.

For a miscellaneous group of plants Mr. Glover, with a bright and nicely arranged collection, including Orchids, Carnations, Chrysanthemums, Primulas, &c., interspersed with Ferns, Crotons, and other foliage plants; and Mr. Tilsell, gardener to R. Graves, Esq., Hatfield House, Twickenham, with a most tastefully and delicately arranged group, largely composed of Ferns and fine-foliage plants, were placed equal first. A third prize was awarded, but the card was not placed on the group.

TABLE PLANTS.—Mr. Waite, gardener to Colonel the Hon. W. P. Talbot, Glenhurst, Esher, was first for nine plants; Mr. Bates, gardener to Mrs. Meek, Poulet Lodge, Twickenham, second; and Mr. King third. For six plants Mr. H. Trussler was placed first, Mr. Buss second, and Mr. Carter third, all staging neat, fresh, and clean examples. Prizes were also offered for amateurs and cottagers; but their exhibits, though many were fairly good, were only of local interest. Some remarkably pretty vases of cut flowers, berries, and foliage, and others of Ferns and Grasses, were much admired.

NEW CHRYSANTHEMUMS.—Blooms of half a dozen new varieties were staged, and after undergoing a close examination by the Judges certificates were awarded for the following:—

Belle Pauline (exhibited by Mr. Molyneux).—It is a Japanese variety; large full bloom, with flat long drooping florets, white clearly margined with deep lilac or light purple. A very fine and, as grown, very charming variety. A similar honour was awarded to Messrs. T. Jackson & Son for blooms of the same variety.

Roseum Superbum.—Large full symmetrical blooms, with rather narrow, drooping, but only slightly twisted florets; prevailing colour pink suffused with amber. This is also a Japanese form, somewhat like Margot, and was exhibited by Messrs. Jackson.

Cullingfordi.—Mr. Orchard exhibited a plant in a 7-inch pot of this—the richest of all *Chrysanthemums*. A grand reflexed flower, velvety crimson-scarlet, one of the blooms being 5 inches in diameter, and the certificate was worthily awarded.

FRUIT.—Some very good collections of fruit were staged, and a splendid lot of Apples and Pears. In the class for a collection of six dishes Mr. Bates, gardener to Mrs. Meek, Poulett Lodge, Twickenham, was first with an excellent Pine, Grapes, Pears, and Apples. Mr. Monro, Cambridge House, Twickenham, second, and Mr. W. Davis, gardener to J. P. Chappell, Esq., Teddington, third. In the class for four dishes of Apples Mr. Child, gardener to Mrs. Slade, Claygate, was first; Mr. Atrill, Bank Grove, Kingston, second; and Mr. T. H. Cushion, gardener to P. Bancroft, Esq., Norbiton Park, third. Pears.—Mr. King, gardener to R. Few, Esq., Norbiton Grange, was first, some others being passed because they were not in accordance with the schedule.

MISCELLANEOUS.—Prizes for berried plants were awarded to Messrs. King, Glover, and Cushion; and for Primulas to Messrs. Carter, Neave, and Buss. Messrs. T. Jackson & Son staged an excellent assortment of fruit, and very productive Vines in pots.

A group of beautiful Tree Carnations from Messrs. Hooper & Co., nurserymen and seedsmen, Covent Garden, London, was much admired, as also was a fine collection of Cyclamens exhibited by Messrs. Page & Son, Grove Nursery, Teddington.

The Show was admirably managed by Mr. T. Jackson the efficient Secretary and his experienced coadjutor Mr. Puttock.

STOKE NEWINGTON—NOVEMBER 9TH AND 10TH.

THE backward season has evidently seriously affected the *Chrysanthemum* growers in the north of London, and the Exhibition which has been most famed for their productions was in consequence both smaller and less notable for the quality of blooms than is usually the case. Incurred blooms are almost invariably remarkable for their neatness and symmetry at the Stoke Newington Show, and it is not often that blooms of unusual size are staged, but we have seen the collections much more even than they were on Monday last, and the plants were not at their best. The Assembly Rooms, Defoe Road, Church Street, was selected for the Exhibition, and a pretty effect was produced by the stands of blooms and specimen plants, the former occupying a row of tables in the centre of the room, the plants being arranged near the walls. Mr. W. J. Smith, Stoke Newington, had an imposing contribution of fruits, and some of the best cut blooms in the Show was a stand of twenty-four from Mr. Cochrane, Superintendent, Finsbury Park.

The principal cut bloom class was that for twenty-four blooms, distinct varieties, in which Mr. S. Gilbey, gardener to B. Booth, Esq., Cazenoves, Upper Clapton, won the premier award with clean, even, medium size blooms, amongst which the following varieties were most remarkable:—*Empress of India*, *Alfred Salter*, *Golden Queen of England*, *Mrs. Heale*, *Lord Alcester*, *Jaune d'Arc*, *Golden Empress*, and *Queen of England*, the others being rather small second and third row blooms. Mr. Payne, gardener to W. A. Mitchell, Esq., Greenville, Upper Clapton, was second. In the open class for twenty-four incurred blooms, distinct varieties, Mr. Monk, gardener to W. Fowler, Esq., Forest House, Leytonstone, was placed first with good medium size examples, comprising a very fine fresh bloom of *Mrs. Heales* and an old one of *Princess of Wales*, quite white, and so much like the preceding that some experienced judges considered them identical. Other noteworthy varieties were *Nil Desperandum*, *Refulgence*, *Queen of England*, *John Salter*, *Lord Alcester*, *Hero of Stoke Newington*, *Jardin des Plantes*, *Prince of Wales*, *Empress of India*, *Baron Beust*, *Lady Hardinge*, *Venus*, and *Empress Eugénie*. The second prize was awarded to Mr. Peers, gardener to F. Cater, Esq., Enfield Highway, who had *Lord Alcester*, *Princess of Wales*, and *Prince Alfred* very fine. The best twelve incurred were shown by Mr. W. Payne, and the next by Mr. Martin, gardener to H. Matthews, Esq., The Cedars, Woodberry Down. Mr. S. Gilbey took the lead with six incurred, and Mr. F. Bingham held a similar place in the local class for twelve incurred, followed by Mr. W. Goldsmith. Japanese varieties were not quite so well represented; Mr. Monk, however, had a good stand of twelve blooms, being first in the class, *Val d'Andorre*, *Golden Dragon*, *Madame B. Rendatler*, *Comte de Germiny*, *Fulton*, and *Madame de Sevin* being the finest specimens. Mr. Calvert, gardener, Southwood, staged the leading six Japanese, the varieties being *Comte de Germiny*, *Boule d'Or*, *Mons. Astorg*, *Madame C. Audiguier*, *La Nympe*, and *Margaret Marrouch*. A class was provided for thirty-six blooms, twelve each of incurred, Japanese, and *Anemones*, but such classes are rarely satisfactory, and there were few entries.

Specimen plants are commonly well shown at Stoke Newington, especially by Mr. Monk, who this year also contributed materially to the Exhibition, winning premier honours for nine plants, but not quite in his usual style. These were half-globular or pyramidal specimens, evenly trained and freely flowered, the varieties being *Tokio*, *La Nympe*, *Triomphe du Nord*, *Sœur Melanie*, *Dr. Sharp*, *John Salter*, *George Glenney*, *Mrs. G. Rundle*, and *Mrs. Dixon*. The second place was obtained by Mr. G. Davey, gardener to C. Paine, Esq., Cedar House, Stamford Hill; the specimen of *Madame B. Rendatler* was an excellent one, but the others were not quite out. Mr. S. Gilbey contributed the best four plants, standards of *Cossack*, *Bouquet Fait*, *Gloire de Toulouse*, and *Cry Kang*. The same exhibitor also had the finest four dwarf specimens, other competitors being Messrs. Monk, Lovegrove, and Bass.

The exhibits were well arranged by the Hon. Secretary, Mr. W. Goldsmith, who is most assiduous in the interests of the Society, and it is to be hoped that the season next year will admit of the Show regaining some of its former prestige.

PUTNEY.—NOVEMBER 10TH AND 11TH.

THIS Society has now been established eight years, and its shows have gradually taken a position amongst the best local exhibitions around the metropolis. This year the Show was an uncommonly good one in all respects, and some considered it the most satisfactory of the series the Society has held. The classes were remarkably well filled, the competitors staging very even collections of blooms, while the groups of plants arranged for effect were the best shown this season at any exhibition up to the present time. The specimen plants were the weakest portion of the display, as they

are at most shows, but in the miscellaneous classes for other plants, fruit, including Apples, Pears, and Grapes, and vegetables, the entries were numerous and the exhibits of good quality. The Assembly Rooms, High Street, Putney, where the Show was held, is rather too small, but the arrangement was carefully superintended, and there was no appearance of crowding, while every part of the hall was effectively furnished. The weather on Tuesday was most unfavourable, and it was therefore fortunate that it had been decided to keep the Show open two days instead of one. The practical Committee and Honorary Secretary, Mr. J. Moore, deserve much credit for the praiseworthy Exhibition provided, and it is to be hoped that a substantial favourable balance will reward their efforts.

Owing to the pressure on our columns this week we can only give a brief survey of the principal classes to indicate the general character of the Show. The groups of *Chrysanthemums* arranged for effect were the strong feature; Mr. Knowles, gardener to Mrs. Egerton, Solna, Putney, winning first honours with a superb collection of healthy plants bearing blooms of wonderful substance, a large proportion being suitable for placing in the cut-bloom classes. The incurred were grand, and the Japanese also of the most beautiful varieties were well represented. They were tastefully arranged, and in all respects it was one of the best groups we have seen. Mr. G. Stevens, Putney, was second, staging good plants, his incurred being extremely fine. Mr. Newell, Fairlawn Gardens, Wimbledon, followed with a very tasteful group of dwarf plants; and Mr. J. Carter, gardener to H. J. Parry, Esq., Heathside, Wimbledon, was fourth. The premier group of miscellaneous plants came from Mr. Methven, gardener to W. Keiller, Esq., Fernwood, Wimbledon, consisting of *Dracenas*, *Heaths*, *Dendrobium nobile*, and *Crotons* effectively and gracefully arranged; Mr. J. Batten, gardener to A. Venables, Esq., Hollywell House, Wimbledon, taking the second place with a pretty group, in which *Impatiens Sultani*, *Primulas*, and *Ferns* predominated. Mr. Sullivan, gardener to D. B. Chapman, Esq., Downshire House, Roehampton, was first with four foliage plants, having three well-coloured *Crotons* and a good *Anthurium crystallinum*. Mr. Woodham had the best four *Ferns*, and in the specimen *Chrysanthemum* classes the finest examples were from Mr. J. Bentley, gardener to Sir Thomas Gabriel, Edgecumbe House, Wimbledon, and Mr. C. Bentley, gardener at The Cedars, Roehampton. There were six neat lots of half a dozen table plants, Messrs. Methven, Bentley, and Smith taking the prizes in that order.

In the cut bloom classes there was some keen competition, and in that for twenty-four incurred varieties five exhibitors staged close even collections. Mr. H. Holmes, gardener to A. B. Hill, Esq., South Row, Clapham Park, secured the chief prize for excellent blooms of slightly more substance than those in the second stand from Mr. Sullivan, though there were few points difference between them. Some of Mr. Holmes' best blooms were *Queen of England*, *Golden Empress*, *Lord Wolsley*, *Lord Alcester*, *Prince Alfred*, *John Salter*, *Empress of India*, *Barbara*, *Beverley*, *Mrs. Heale*, *Lady Hardinge*, and *Cherub*. Mr. J. Bentley was placed third with a stand of twelve incurred. Mr. Sullivan took the lead with capital blooms, followed by Messrs. J. Bentley and A. Holmes, while for six incurred Mr. J. C. Grant, gardener to J. Brunlers, Esq., Argyle Lodge, Wimbledon, Mr. C. Bentley, and Mr. J. Batten were the prizetakers in that order. The exhibits of twelve Japanese varieties were close and good, Mr. J. C. Grant gaining the principal award for substantial blooms, in which *Mr. Ardene*, *Madame C. Audiguier*, *Madlle. Lacroix*, *Henri Jacotot*, *M. Astorg*, *John Laing*, and *J. Delaux* (F. A. Davis) were notable. Mr. Sullivan and Mr. W. Smith, gardener to J. F. Schwann, Esq., Oakfield, Wimbledon, were second and third. Mr. C. Bentley staged the best six Japanese, handsome blooms of *Boule d'Or*, *J. Delaux*, *Yellow Dragon*, *Sultan* and *Val d'Andorre* being included. Messrs. Sullivan and Bennett were the prizetakers with six Japanese *Anemones*, the former staging *Fabian de Mediana* and *Sœur Dorothee Souille* in good form, and was also first with six large *Anemones*. Mr. H. Holmes was awarded chief honours for six incurred of one variety, staging grand blooms of *Queen of England*. Messrs. Woodhams, Methven, and Smollett were the winners with *Pompons*; Mr. W. Furze, Roselands, Teddington, being first in the classes for single-handed gardeners with twelve incurred and the same number of Japanese.

In the fruit classes the entries were very numerous, there being thirteen competitors with three dishes of Pears. Mr. Alexander, gardener to W. M. Seamen, Esq., Tower House, West Hill, was first with *Souvenir du Congrès*, *Flemish Beauty*, and *Pitmaston Duchess*. Apples were similarly well represented, the principal prizes being taken by Messrs. Whitebread and Smollett. Mr. W. Smith was first in the black Grape class with large bunches of *Alicante*, followed by Mr. Alderman with three even handsome bunches, both well coloured. Mr. Alderman was first with well-ripened *Muscat of Alexandria* in the white Grape class, followed by Messrs. W. Smith and Batten. The leading collection of vegetables was from Messrs. Tigwell, Mortlake, and the most tasteful bouquet of *Chrysanthemums* was from Mr. G. Stevens, a pretty combination of red and bronze Japanese varieties. The other bouquets were much too crowded and far from graceful or praiseworthy.

SOUTHAMPTON, NOVEMBER 3RD AND 4TH.

THE annual Exhibition of the Royal Horticultural Society of Southampton was held at the Victoria Skating Rink on the dates named. Owing to the lateness of the season and the early date of the fixture the entries were not quite so numerous as on former occasions; still, sufficient plants and blooms were staged to make a capital show. Several new exhibitors in the *Chrysanthemum* classes made their first appearance at this Show, and they competed in the various classes. One noted exhibitor in the cut-bloom classes we missed from the list—namely, Mr. Molyneux, who was no doubt reserving his strength for the Kingston Exhibition, to take place the following week. Cut blooms were numerous shown and in good quality. Plants were of large size, profusely flowered, and neatly trained, without being too stiff. Apples and Pears were numerous staged and grand in quality, while Grapes were well represented. Vegetables, too, were quite a strong feature, so excellent in quality were those staged. Amateurs and cottagers came out in strong force, as is always the case at this place. Under the able direction of the Secretary, Mr. C. S. Fudge, everything passed off well.

For the best group of *Chrysanthemums* arranged in a space 8 feet by

5 feet, quality and general effect to be the leading features, there were only two exhibitors. The first prize was awarded to Mr. J. Allen, gardener to J. Bailey, Esq., Glenfield Hill, Southampton, for a capital group, dwarf plants with fresh foliage, and carrying good blooms of the leading varieties. Mr. N. Blandford, gardener to Mrs. Haslefoot, Moorhill, West End, Southampton, was second. Mr. J. Allen was first for six plants, with large handsome specimens freely bloomed, notably Dr. Sharpe and Lord Alcester. Second Mr. W. Joy, nurseryman, Shirley, with larger plants, but not quite so well bloomed. Mr. Joy was first for six Japanese plants with specimens 5 feet in diameter and carrying 120 blooms on each plant. The same exhibitor was first in the nurserymen's class with plants somewhat similar in character. Mr. E. Wills, gardener to Mrs. Pearce, The Firs, Bassett, had the best single specimen of incurved or reflexed with Dr. Sharpe, splendidly coloured, the flowers numbering 150. Mr. Allen and Mr. Joy were second and third.

For twenty-four varieties incurved blooms Messrs. W. & G. Drover, florists, Farnham, was first with even, neat, fresh examples, well staged, the following being some of the best varieties:—Jeanne d'Arc, Empress of India, Lord Alcester, Hero of Stoke Newington, and Jardin des Plantes. Mr. C. Penford, gardener to Sir F. Fitzwygram, Bart., M.P., Leigh Park, Havant, was second, his blooms lacking the quality and finish of the first-prize collection, Queen of England, Golden Empress of India, Miss Mary Morgan, and Lady Hardinge being some of the best. Third Mr. J. Allen.

Mr. Penford staged the best twenty-four blooms of Japanese Chrysanthemums, among which were large fresh examples of Oracle, Balmorean, and J. Delaux. Second, Mr. W. Neville, gardener to F. W. Flight, Esq., Cornstiles, Twyford, Winchester—Margaret Marrouch, M. Delaux, and Mlle. Lacroix being specially noteworthy. Mr. Neville had the best twenty-four blooms in eighteen varieties, with a clean, even, well-arranged lot; the best were M. Marrouch, J. Delaux, Lord Wolsely, and Jeanne d'Arc. Mr. H. W. Ward, gardener to the Earl of Radnor, Longford Castle, Salisbury, herein made his début as a Chrysanthemum grower, and some right good examples he staged. Third, Mr. J. Allen. Fourth, Mr. C. Warden, gardener to Sir F. Bathurst, Bart., Clarendon Park, Salisbury, who in his staging took quite a new departure, showing the blooms as grown (which were good) with stems and foliage set up on moss, and having an edging on the front of his stand of *Isolepis gracilis*; this exhibit was very conspicuous if not meritorious. Messrs. Drover had the best stand of twelve incurved, while Mr. C. Penford set up the best twelve Japanese, closely followed by Mr. W. Wildsmith, gardener to the Right Hon. Lord Eversley, Heckfield, Winchester, all staging produce of high merit. For twelve blooms Anemone flowered, and the same number of reflexed, Mr. C. Penford was awarded first prizes for very fine stands, followed by Messrs. Drover and Wildsmith.

In the class for twelve blooms shown with foliage as grown, Mr. Allen was first, followed by Messrs. Neville, Warden, and Penford. Mr. Molyneux, gardener to W. H. Myers, Esq., Swanmore Park, had the best Pompons, closely followed by Mr. Wills. Mr. Wildsmith was first for twelve blooms not less than eight varieties, conspicuous amongst them being fine flowers of Mame. C. Audiguier, Golden Queen of England, and Lady Hardinge. Second, the Right Hon. H. Crichton, Netley Castle (gardener, Mr. J. Reynolds). Miss Flight had the best-arranged stand with Chrysanthemums and other flowers, which was quite charming in its effect.

Mr. Ward staged the best Grapes in the class for three distinct varieties, Mrs. Pince being very fine in bunch and berry, Gros Guillaume large in berry and splendidly coloured, also Muscat of Alexandria. Mr. J. Budd, gardener to F. G. Dalgety, Esq., Lockerley Hall, Romsey, was second with fine Muscat of Alexandria and Alicante. Mr. T. Hall, gardener to Captain Davison, South Stoneham House, was third, his bunch of Alicante being superb in every way. Mr. Molyneux had the best three bunches of black Grapes, with specimens of Gros Guillaume weighing collectively 16 lbs., perfect in berry and colour. Mr. Hall followed with Alicante carrying a dense bloom, while Mr. T. Grant, gardener to Major Murray, Ossemsley Manor, Christchurch, was third with the same variety in fine condition. Mr. W. Saunders, gardener to J. East, Esq., Longstock House, Stockbridge, was first for three bunches of white Grapes, with Muscat of Alexandria, almost faultless. Second and third, Mr. Ward and Mr. Budd. Mr. Penford had the best two bunches black and white Grapes, while Mr. Ward's bunch of Gros Guillaume weighing 10 lbs. gained him the premier award. Mr. Wildsmith had the best Pine Apple. For four dishes of culinary Apples, any variety, Mr. G. Busby, gardener to F. Willan, Esq., Thornhill Park, Bitterne, was first, closely followed by Mr. Hall. The former had fine dishes of Lady Henniker, Golden Noble, and Waltham Abbey Seedling. King of Pippins, Ribston Pippin, and Cox's Orange Pippin gained for Mr. Wildsmith the premier award for dessert Apples, so rich in colour were they; second, E. H. Goodwin, Esq., amateur; third, Mr. G. Busby; seventeen entries. Mr. Godwin gained first prize for three dishes of kitchen Apples. Mr. Sanders gained a like award for four dishes of Pears with extra large specimens of General Todtleben, Pitmaston Duchess, Uvedale's St. Germain, and Doyenné du Comice; Mr. R. West, gardener to J. R. W. gram, Esq., Northlands, Salisbury, second. Mr. Sanders was again first for three dishes of Pears. Mr. E. H. Goodwin had a splendid dish of Filberts, which gained him the first prize. Mr. Wills was first for table plants, six Palms; while the collection of Orchids staged by Mr. N. Blandford made quite an imposing array, *Calanthe Veitchii* and *C. vestita rubra* having splendid spikes of bloom.

Vegetables were represented by nine collections of eight varieties, and grand lots they were. Mr. J. Cox, gardener to R. K. Wyndham, Esq., Corhampton House, Bishops Waltham, was first, Lyon Leeks (grand), splendid Autumn Giant Cauliflowers, White Gem Celery, Rousham Park Onion, and Improved Magnum Bonum Potato. Mr. W. Pope, gardener to the Earl of Carnarvon, Highclere Castle, Newbury, was second, Tomatoes, Carrots, and Cauliflowers being particularly strong. Third, Mr. Sanders. Mr. Budd had the best salad.

Messrs. Lucombe, Pince & Co. staged a fine collection of Apples and Pears, the former numbering 180 dishes, while the latter contained fifty-two dishes; all were of large size and splendid colour. Mr. Wildsmith staged six Pine Apples, not for competition, which were of fine quality.

NATIONAL CHRYSANTHEMUM SOCIETY.—NOVEMBER 11TH AND 12TH.

A most successful Exhibition was opened at the Royal Aquarium, West-

minster, yesterday, and continued on Thursday, the cut blooms being of high quality, and the groups from Mr. G. Stevens and Mr. N. Davis some of the best ever shown at the Aquarium. Fruits, especially Grapes, Apples, and Pears, were extensively and well represented; the vegetables in competition for Messrs. Sutton & Sons' and Messrs. E. Webb & Sons' prizes being also of high quality. Messrs. H. Cannell & Sons contributed a most tastefully arranged collection of Chrysanthemum and other blooms, Messrs. Lee & Sons having having a large collection of Apples, and Messrs. Sutton and Sons a similar one of Potatoes.

One of the principal classes was that for forty-eight incurved, the first prize being £10; but, strangely enough, only one exhibitor appeared—Mr. C. Penfold, Leigh Park, Havant, and he was awarded the second prize. The Veitch Memorial Medal and £5 prize brought four good collections of thirty-six incurved blooms, Mr. Gibson, gardener to J. Wormald, Esq., Morden Park, Mitcham, taking the coveted honours with grand blooms. Mr. E. Berry, gardener to the Countess of Leven and Melville, Roehampton, was a close second with very even blooms. For forty-eight blooms Mr. J. J. Lewry, gardener to J. Macandrew, Esq., Belmont, Mill Hill, took the lead in a strong class with magnificent examples of the best varieties. Mr. Ridout was second also with fine blooms. First prizes were also awarded to the following exhibitors:—Mr. J. Bettisworth, gardener to R. Ewing, Esq., for twenty-four Japanese; Mr. Shoosmith, gardener to Canon Hodgson, Saltwood Rectory, for twelve Japanese and twelve incurved; Mr. Sullivan, gardener to D. B. Chapman, Esq., Downshire House, Roehampton, for twelve large Anemones; Mr. E. Sanderson, Willesden, for twenty-four incurved; Mr. C. Langdon, Brooke House, Clapton, and Mr. J. J. Hillier, Priory Road, Wandsworth Road, being first in the amateur and metropolitan classes for twenty-four and twelve incurved blooms.

Four handsome groups were staged by Mr. G. Stevens and Mr. N. Davis, one of Japanese and one of incurved varieties each, and they took first and second prizes in the order named. In other plant classes Mr. Gilbey, gardener to F. Moore, Esq., Blendon Hall, Bexley, had some of the best specimens, evenly trained and well flowered.

Eight collections of Grapes, twelve bunches were entered, Mr. W. Pratt, Longleat Gardens, Warminster, winning the first prize (£8) with beautiful Alicantes, Lady Downe's, and Muscat of Alexandria. Mr. Wallis, Keele Hall, Newcastle, Staffordshire, was second, showing a superb bunch of Mrs. Pince; and Mr. Osman, Ottershaw Park, Chertsey, was third. In the class for black Grapes Mr. Howe, Park Hill, Streatham, was first with three grand bunches of Alicante, weighing 15½ lbs.; Mr. S. Castle, West Lynn, Norfolk, following closely with Gros Colman in fine condition, the berries of great size. This exhibitor won also first with Muscat of Alexandria, in the white Grape class, followed by Mr. Wallis. The best Apples were from Mr. W. Jacobs, Petworth, and Mr. C. Ross, Welford Park Gardens, Newbury; the first-prize Pears coming from Mr. C. J. Goldsmith, Kelsey Manor, Beckenham. Messrs. Sutton & Sons' prizes for a collection six sorts of vegetables brought ten competitors, Mr. A. Miller, gardener to H. Long, Esq., M.P., Rood Ashton Park, Trowbridge, being awarded first honours for clear even samples of Stamfordian Tomatoes, Rousham Park Hero Onions, Cauliflowers, Leeks, Schoolmaster Potatoes, and Sprouts. There were six entries for Messrs. Webb's prizes in vegetables; Mr. Haines, gardener to the Earl of Radnor, Highworth, leading with an admirable collection, the Leeks, Cauliflowers, and Onions being wonderfully fine.

CROYDON.—NOVEMBER 11TH AND 12TH.

THE Croydon Horticultural Society held their ninth annual autumn Show on the above dates. The Chrysanthemums were, of course, the most important feature and were shown fairly well, as also was fruit. The following are brief particulars of the awards:—

CUT BLOOMS.—Incurved.—The leading class was that for twenty-four flowers, and the first prize went to Mr. Gibson, gardener to J. Wormald, Esq., Morden Park, for excellent specimens of the best-known varieties. Mr. H. Alderman, gardener to G. Hatfield, Esq., Morden Hall, was a moderate second; no others competed. For twenty-four incurved flowers, open to local gardeners, only, Mr. T. Sadler, gardener to C. Lambert, Esq., Streatham, was first and Mr. Rodbourn second; no others in competition. Twelve moderate blooms secured Mr. Rodbourn the first prize in the next class, Mr. Cook being second, and Mr. Ridge, gardener to Lady Ashburton, Addiscombe Farm, third; four others competed. For six blooms Mr. A. Alderman was first with medium sized, but fresh and nicely finished flowers; Mr. Cook was second. Six blooms of one variety (three entries).—First Mr. Rodbourn, with good specimens of Golden Empress of India; second Mr. Staines, gardener to J. Newton, Esq., Parkhill, with Mrs. Dixon; third Mr. Terry, gardener to J. H. Gwyther, Esq., Parkhill, with Mr. G. Glenny.

JAPANESE.—Mr. Gibson was again victorious in the principal class for these, winning easily with splendid blooms. Mr. H. Alderman was again second, and Mr. Rodbourn, gardener to Baroness Heath, Coombe House, third. In the local class for twelve Japanese an excellent stand from Mr. A. Alderman was an easy first; the flowers were not large, but beautifully fresh. Mr. Rodbourn was second, and Mr. Sadler third. For six of one variety Mr. A. Alderman was first with M. Delaux, very fine, and third with J. Delaux; Mr. Staines second with Elaine; Mr. Rodbourn equal third with Triomphe du Nord.

Twelve large Anemone-flowered, two entries.—First, Mr. Rodbourn; second, Mr. Cook. The flowers of the first-named exhibitor were excellent. Twelve Anemone Pompons, two entries.—First, Mr. Cook; second, Mr. Dobson, gardener to Miss Stenning, Addiscombe Road, Croydon. Twelve cut blooms, with foliage, seven entries.—First, Mr. Welstead, gardener to Mrs. Lodge, Bramley Hill; second, Mr. Sadler; third, Mr. Rodbourn.

GROUPS AND SPECIMENS.—Mr. George Curd, George Street, Croydon, took the first prize for a group of Chrysanthemums, open; it was well arranged, and produced a good general effect. Mr. C. S. Bowman, London Road, Croydon, was a very good second. Only one collection was staged in the local class, a very nice group from Mr. Cook, gardener to J. Ezekiel, Esq., Duppas Hill, Croydon, being adjudged first prize. For three plants on single stems Messrs. J. Cook and Sadler were first and second respectively. Three Pompons:—First Mr. Cook, only one entry. Single specimen:—First Mr. Cook (Madame B. Rendatler); second Mr. Sadler (Geo. Glenny).

KITCHEN GARDEN.

GLOBE ARTICHOKE.—We have frequently wintered these in the south without any protection, but our readers in the north must not risk this, and in all cases it will be well to protect them when frost comes. Indeed, where litter is plentiful the whole might be done at once, and they will be safe for the winter. Do not cover the head, but place a good quantity of the manure around the neck of each plant. Our plants have lately grown fast. They were rather checked with the dry weather in July and August, which may have caused them to die earlier, and the moisture in September induced them to grow again luxuriantly. Young heads are forming, and should the weather remain mild we shall cut several dishes before November is out. This extra growth will, no doubt, have occurred with many, and it ought to be preserved if possible by protecting now as suggested. When the weather has come very severe we have sometimes thrown straw covering over the whole of the tops, but this is not necessary as a rule.

RHUBARB.—We know of some excellent growers of this who assert that the proper time to feed Rhubarb is in winter, and our practice verifies this. We rarely feed our Rhubarb in summer, but mulch it heavily at this season with strong manure, and the growths are always as plentiful and strong as we could desire them. Young roots in recently manured rich ground will not require any feeding, but old roots which have been growing for a number of years in the same spot will be greatly benefited by it. They do not want protection, therefore light stuff with no substance in it need not be put over the plants, but strong juicy cow or pig manure should be used. Spread it over the surface so far as the roots extend at least, and put it on 4 inches thick.

BROAD BEANS.—These may also be sown at the same time as the Peas. The drills may be from 3 feet to 4 feet apart, and the depth 4 inches. They will succeed in a much heavier soil than the Peas; but if put into this alone the seed may decay, and it is a good plan to open the drills 6 inches deep, place sand or light soil in the bottom to the depth of 2 inches, tread this down, sow the seed, and fill with more fine soil or sand. This will prevent decay of the seed, and as the roots go downward they will not depend on any of the light surface soil for nourishment. In spring and summer we generally sow our Beans singly 2 or 3 inches apart, but now they should be put closer than this.

ENDIVE.—This is a most valuable and acceptable addition to salad plants in winter. We value the Broad-leaved Batavian variety more than any other salad plant we possess from November until March. We grow it largely and exclusively. The Green Curled is pretty, but not so useful as this excellent broad-leaved sort. The plants grow very large, and are very hardy. Like other Endives, they require tying up a fortnight before being used, and quantities ought to be tied up now for use during the latter part of this month and throughout December. Gather the leaves all together at the top, bind them round, and tie them close with a piece of matting, and the centres will soon become tender and cream-coloured. We always tie them when quite dry, and as the rain cannot penetrate to the centre easily when the leaves are tied at the top we do not lose many plants from damp. They will bear a few degrees of frost, but in very severe weather, or just before this, a large quantity should be lifted, placed in cool frames, and covered over with lights. When frames were not available we have sometimes placed numbers of them close together on the inside border of a cool Peach house, and they kept uncommonly well there. So long as they can be kept dry there is little danger of their decaying.

CHICORY.—A number of roots of this should be lifted and put in eights or tens into 9-inch pots for forcing. Cut all the top leaves away before pitting. Any soil will suit, and a temperature of 65° or 70° will soon cause fresh leaves to be emitted. When kept in a dark place they come a beautiful creamy colour, and are tender and juicy. Chicory is easily grown in summer, still easier forced in winter, and is much valued in made-up salads. With a good supply of this and Mustard and Cress no one need dread the destruction of their Lettuce by frost.

CABBAGE.—The snails have been busy amongst the Cabbage plants, and we observe many blanks, which will be filled up on an early day. All plantations should be looked over now with the object of doing this, as young plants put in now will begin to root before severe weather, and they will grow freely with the earliest in spring. It is not desirable, however, that there should be too many blanks, and the surface of the soil where the plants are growing should be dusted with a little fresh lime. Our winter Spinach and late Turnips are hardly so good now as in former autumns. They never quite got over the drying up they experienced when young and tender in August.

FRUIT FORCING.

CUCUMBERS.—As soon as the roots protrude through the surface of the mounds add more soil to the hillocks, which should have been previously warmed to the temperature of the house and be in a moist condition, so that the roots will enter through it at once. Complete earthing the first autumn plants, and mulch at once with decayed manure, which will attract the roots upward and act as a stimulant. The waterings should be

copious and as frequent only as necessary and according to the requirements of each plant. It should be given at a temperature of 75° to 80°. When to apply and to withhold water can only be determined by those in charge and possessing a practical knowledge of the wants and condition of the plants, and even then the application or non-application of water to the roots must be determined by circumstances, as the mode by which bottom heat is obtained, and the scope of root-action possessed by the plants, as well as by their condition and appearance generally. The fires on bright mornings should be stopped, or the heat turned off about eight o'clock, by which time the sun heat will take the place of artificial heat, and is much better for the plants. It does not answer to keep the fires going until the day temperature is reached, as the sun as well as the fire heat has increased in force, rendering ventilation immediately necessary to prevent the temperature rising too high, as to lower it is not only wasting heat, but letting in cold air which will produce a chill. The fires should be again started in the afternoon as the sun is decreasing in power and going off the houses, so that by the time the sun heat, husbanded by early closing, is exhausted, the heat from the pipes may be sufficient to secure the temperature at 65°, or in the event of severe frost a night temperature of 60° is ample. To maintain this the piping should be liberal, while to economise fuel, and to obtain a more genial heat, it is a capital plan to cover the roof of the house or pit at night with mats. The temperature in the day should range from 70° to 75° by artificial means, and 80° to 85° from sun heat, and no opportunity should be lost of utilising solar heat for the growth of the plants by careful ventilation. If mildew appears dust at once with flowers of sulphur, and keep the house rather drier and ventilate more frequently. If aphides appear fumigate, but it must be done moderately, and on two or three consecutive evenings. If canker show on the stems rub quicklime well into the affected parts, repeating it until the parts become dry and healed.

As the first plants are showing fruit freely all superfluous ones should be removed at once, as on the judicious cropping of the plants during this month and early December depends the success of a supply of fruit from Christmas to March. Crop lightly and otherwise attend to the stopping and thinning, also tying of the shoots, allowing no more than can have free exposure to light, removing any decayed portion of growth or foliage that may appear, and keep the glass clean, so that all the light possible may be secured to the plants.

STRAWBERRIES IN POTS.—The early plants of varieties intended for early forcing have well-developed crowns, and be in a state of rest and in cool quarters, though with lights over them to shelter them from heavy rains. Towards the close of the present month early plants of some approved varieties will need to be started in gentle heat with a view of having ripe fruit about the middle of next February. Of all those we have tried preference is given to La Grosse Sucrée, on account of its fruit being larger than many others, besides setting well, swelling well, and being of a bright red colour. At the same time, plants of Vicomtesse Hericart de Thury and Sir Harry may be started, as we find it best not to rely exclusively on one variety, and all are good. Black Prince is still grown by some, and if worth forcing at all it should be as a first early, but we have discarded it. In the meantime the plants should have their drainage examined and rectified where it is at all deranged, and the pots freed of moss, &c., by washing. Any decayed leaves should be removed, but avoid dressing them very close, stirring the surface of the soil and removing the inert matter without damaging the roots, afford a top-dressing of fresh horse droppings rubbed through the hands with a sprinkling of bone dust, into which they will root, being a means of encouraging surface roots, and with these there is certain to be plenty in the pots when the plants begin to make top growth. For early work a Strawberry house is best, but in its absence, as it unfortunately is in only too many places where Strawberries are wanted and must be had early, a Peach or other forcing house started at the same time as the Strawberries will be a suitable place to bring forward the plants, they being assigned a position near the glass and where they will receive plenty of air without it coming directly upon them. For the first fortnight the house should only be closed, no fire heat being used except to exclude frost, taking advantage of sun heat to close the house so as to induce gentle excitement, and the night temperature will not fall much, if any, below 50° at night unless frost prevails. During the early stages of forcing the temperature by artificial means ought not to exceed 50°.

Fruiting plants will require to be sparingly watered, and will need a position near the glass in a house with a rather dry atmosphere and with a temperature by artificial means of 60° to 65°.

PLANT HOUSES.

Calanthes.—The flower spikes of the earliest plants will be advancing rapidly, and if earlier than they are required they may be retarded by placing them in a temperature of 50° to 55°. Plants in this stage must be watered very carefully, for nearly all the foliage has ripened naturally, but the roots remain active for some time afterwards if not destroyed by suddenly withholding water from them. When the roots naturally die it is useless to apply water to them afterwards, but until they reach this stage the soil should not be destitute of moisture. The atmosphere in which they are placed should be moderately dry, for the flowers last nearly double the length of time under these conditions than is the case in a warm moist structure. Calanthes are effective when in bloom arranged amongst Adiantums or other Ferns, which hide the pots and display to much advantage the light arching spikes of white and rose-coloured flowers. They are also very useful in the conservatory, arranged amongst Pelargoniums, Primulas, Cyclamens, and other dwarf flowering

plants, if the temperature in that structure is kept from falling below 50° at night. Late batches for flowering after Christmas must be regularly supplied with water as they need it, for they still possess the whole of their foliage. These must not be in a lower night temperature than 60°.

Dendrobiums.—Many of these have completed their growth, and should receive no more water at their roots or moisture in the atmosphere than sufficient to keep their pseudo-bulbs fresh and plump. The majority of deciduous varieties after the whole of the foliage has been ripened from them may be removed to a cool house, where they will have a season of rest, which is essential to luxuriant growth. Some, such as *D. Devonianum*, *D. crystallinum*, and others, are not benefited by removal to a cold house, for they rest perfectly, flower profusely, and grow better another year if they are rested in an intermediate temperature; if starved while at rest they are liable to go back instead of making progress the following year. Many evergreen varieties, such as *D. nobile*, will also be ready for removal to a cool house, but those that have not completed their growth must be kept in heat and their pseudo-bulbs ripened as early as possible. *D. thyrsiflorum*, *D. densiflorum*, *D. Farmerii*, and others of similar habit have completed their growth, and may be removed for a time to an intermediate temperature to further ripen, and finally subjected to cool treatment. They must be well ripened and not placed to rest in too low a temperature, or the tips of the leaves turn yellow, and therefore destroy the appearance of the plants. When placed under cool treatment it is necessary to keep the atmosphere perfectly dry. *D. heterocarpum*, *nobile*, and *Wardianum* that have been resting some time in a cool place will be showing their flower buds prominently on each side of the pseudo-bulbs; these can soon be brought into flower by introducing them into the stove or any other house where a temperature of 60° is maintained; if not required they can still be retarded, or placed in a house to come forward less rapidly.

Cattleyas.—All plants that have completed their growth should be removed to the coolest end of the house in which they are grown, while those still growing must have the lightest and warmest end. These plants will need very little water either at their roots or in the atmosphere. Those that have ceased growth will only need sufficient water to maintain their pseudo-bulbs and foliage plump. *Cattleyas* often make a good quantity of roots after the pseudo-bulbs appear to be full grown and ripe. These must not be prematurely sent to rest by withholding water, but it must be applied to them carefully and cautiously until root-extension is fully completed. It will be unnecessary to damp amongst the pots of these plants from the present time, for the atmosphere will be rendered sufficiently moist by the water required at the roots of the plants. The night temperature should range from 55° to 60°, with a rise by day of 5° or 10°. Ventilate whenever the weather is favourable. Under these conditions *Cattleyas* will rest, without which they will not long remain in perfect health. While in an inactive state these plants are very liable to the attacks of thrips, which, if not destroyed, will soon seriously injure their foliage.

Oncidiums.—The majority of these will be better with the *Cattleyas* from the present time than in a warmer structure. Some are benefited by a lower temperature, but the *Odontoglossum* house is too moist for them. If these plants are to grow well and flower profusely they must have their pseudo-bulbs well ripened, and then the plants receive a complete rest for a good period by keeping them in a cooler house than the one in which they have been grown. They should also be kept dry at their roots; in fact, only give sufficient water to prevent their pseudo-bulbs shrivelling.

THE BEE-KEEPER.

SKEP COVERINGS.

THIS apparently simple matter of coverings for straw hives is a cause, when not properly attended to, of much loss and no small amount of anxiety to the bee-keeper; for during the damp wet days and weeks of the winter months, unless the coverings are such as to entirely obviate any chance of the wet penetrating through and causing a dampness on the top of the hive; or if by reason of there not being sufficient overlap or slope the wet runs from the floorboard under the sides of the hive, causing damp and mould, a foundation has been laid for disease which, unless speedy precautions are taken, will destroy the stock. Mr. Payne in his manual—which I am sorry to say I am unable to obtain, it being now out of print, and my own copy mislaid by a cottager to whom I lent it—said, if my memory does not mislead me, that a large earthenware pan was the best protection for a hive from the weather.

There appears, however, to me to be a great objection to such a cover, in that when rain comes driven by a wind it beats beneath any such protection and wets the hive through, with the result that during the winter the hive is continually damp, and the floorboard also is affected in the same manner.

Such a state of things would cause me the greatest anxiety, and even if no harm ensued it would be a perpetual eyesore which would render it an impossibility in any apiary. What, then, is the best substitute? Now on this question so much has been written, and such lavish abuse of boxes has been poured out, that it is with a feeling of half fear that I venture to say that for cleanliness, neatness, dryness, ease in supering, ekeing, nadiring, and for general adaptability to all the operations conducted in an apiary there can be no better covering than a well-made box.

Such a box could be made at a very small cost, and the way I set to work is as follows:—From any shopman I procure a good strong box which generally costs about 6d., and is larger than the largest hive ever used here, and deeper by 6 or 8 inches at least. I then get another box of good sound material at the same price; with the wood of this second box form a roof for the other, making it of such a form as to give ample room for filling supers; this top is loose and held on the box merely by hooks and eyes. A good coat of thick paint once a year completes the whole, which will last for years—in fact, with common care such a box will outwear most bee-keepers. The cost of labour in construction is not much—to a man, that is, who knows how to use his hands, and if it seems not to be so easy to form the top from the second box a little extra outlay will buy wood sufficient for the roof. It may be added to the directions already given that the front side of the box is knocked out, and, after an entrance has been cut for the bees, the front board as it now becomes is fastened on again by means of two brass-headed thumb screws, so as to be easily removeable whenever necessary. One word of warning. Good work is essential. To expect a box only half made and put together in a loose happy-go-lucky fashion to keep out wet effectually is ridiculous, but, on the contrary, a good properly made box will entirely keep out such moisture, and the room at the top and the sides will have a beneficial effect in winter by keeping up a free circulation of air, and this is a point to which I pay particular attention, always leaving spaces under the eaves to admit air freely, and yet so contrived as to exclude wet. Thus the stagnation of air which propagates and fosters damp is superseded by the health-giving changes of air continually going on.

Now, what is the result of having our skeps under these shelters? The advantage are manifold, of which I may state the chief. These are the knowledge that no wet can penetrate, and that mice are effectually excluded; the additional facility given for the use of any kind of super either sectional glass or of any other description; the advantage gained by preventing the sun in winter from warming the hive too quickly, and so enticing the bees to leave their comb when the outside air is quite unfit for flight; and last, but not least, the preservation of the hive itself from the destructive effects of damp and exposure to weather. These, then, seem to be the advantages, and of the disadvantages I can say nothing, for apparently they are an “unknown quantity.”

I must, however, now leave the subject to the sense of bee-keepers, who can after reading think the matter over and compare the boxes with the style of coverings they have in use, and consider whether the cost of a lasting covering will not soon be repaid and a saving effected by its adoption; and, last of all, let me advise them to act according to their idea of the comparative utility of the different styles of skep protectors—to discard the one and use the other, and so to act as it seems to them most likely to conduce to ultimate profit.—FELIX.

THE CALEDONIAN APIARIAN SOCIETY.

At the recent meeting of the above Society held in Glasgow the principal counties from Inverness to Wigtown, Ayrshire, Argyleshire, Perthshire, Stirlingshire, Lanarkshire, &c., were well represented. On the revision of prize list some alterations were made. Mr. J. Anderson of Dalry, Ayrshire, said, to please the whim of a few novices, the most of the prizes for the produce from the Stewarton hive had been withdrawn. He begged now to propose that in consequence of the Stewarton hive

coming more into repute more prizes be offered for supers, which did not deprive those from other hives competing. This was unanimously agreed to. Prizes to farmers' wives and daughters, which were offered to encourage that class in bee-keeping, appeared in the schedule as ladies' prizes. Mr. William Thomson, Lanarkshire, said those prizes had been unfairly taken advantage of by bee-keepers, members of this Society, entering their wives for and gaining these prizes, thus defeating the real object they were intended for. He moved that farmers' wives and daughters only be substituted. This was agreed to by a small majority. Mr. Thomson then suggested that prizes should be offered in greater number for articles made from honey. Major R. J. Bennett, Honorary Secretary, stated that he had a letter on the subject from the Rev. Mr. Moyle, advising the extension of prize list for comestibles, &c., made from honey. These suggestions were agreed to. The foregoing were the principal alterations of the prize schedule for 1886, to be competed for at Dumfries in July, where the Highland and Agricultural Societies' Show will be held.

Major R. J. Bennett then read an interesting paper on the seasons and bee-keeping since 1874, as well as a statistical account of honey and wax imported into this country, urging upon all bee-keepers to do their utmost in securing what the country would yield in honey and wax, and keep the £200,000 expended on the foreign article within our own country. The Major in his discourse pointed to many things which would be of great advantage to bee-keepers, but prominently and of the highest importance was that of judicious crossing and keeping only young and fertile queens. Sometimes, he said, after we thought we had our ends attained, some of the queens would remain sterile or partly so. Sometimes queens would at first fail to come up to the standard, but after a short time become very fertile. One common cause of sterility in queens was defective organism, but this was not always the case. The fault lay often with the drone. There had been too little attention given to this important part of apiculture. It was a recognised fact that the best queens were had from strong hives. The same applied to drones. The weakening of stocks by excessive swarming and the pruning of drone comb from the centre of hive reduced the vigour of the drones. He was sure the subject was one that required consideration. They had the evidence of "A Lanarkshire Bee-keeper" of the superiority of judicious crossing by drones from strong stocks and foreign races, as well as that of the Messrs. McNallys with their nearly 2 tons of honey, and in a few years instead of having to import honey and wax much might be exported.

Mr. Thomson said that bee-keepers situated far from towns of importance found a difficulty in marketing their produce. To meet this want he had been trying to establish a system that would enable them to have a sure place where they could consign their honey, where it would be sold at a moderate yet remunerative price, without being compelled to sell to honey companies at a price that would do little more than pay for the carriage. To meet this want Mr. Thomson said he had appointed several agents who were willing to sell on commission Scotch honey only, providing the bee-keepers would advertise; he now wished to know whether this meeting would agree to these proposals, and assist bee-keepers, whom they had instrumentally encouraged to start bee-keeping, to get rid of their honey. Major Bennett said the proper course to pursue was to send their honey to some broker to be sold by auction. Mr. Thomson opposed this course on the ground that honeycomb was of too delicate a nature to stand the rough treatment of auctioneers' assistants and railway porters; besides, merchants often acted in concert, and kept down the price, as they have already done with both fruit and honey when there was much on sale, while the public seldom benefited from the low public sale prices. This question was now dropped, the Society declining to take any action.

After the formal vote of thanks to the Chairman and Honorary Secretary, Mr. Sword said he could not close the meeting without paying some deference and honour to those who had the interests of bee-keepers at heart, but were prevented from being present on account of ill health or other circumstances. He begged the meeting to remember that there was one who was the prime mover in all relating to apiculture, and was one of the few gentlemen who successfully launched this Society, and was he who was the successful competitor in driving and transferring at the Kibble Crystal Palace Botanic Gardens, Glasgow, in 1876, where he gave his unsuccessful opponent (Mr. Abbott) so salutary a lesson in the art and "mysteries" of the hive. That gentleman, Mr. John Wilkie, late of Greenock, is now in New Zealand as enthusiastic and, he hoped, a successful bee-keeper. He therefore proposed the health and prosperity of Mr. Wilkie.

The meeting resolved itself into a conference, when Major Bennett entertained them to luncheon. Many topics on apiculture were discussed. Amongst them was that of queen-introduction. Success was claimed in various ways, but all seemed to agree that the only safe plan was to deprive the bees the power of raising another queen. Mr. Thomson said he had killed as many queens, or perhaps more, than any other person. These deaths were caused by pursuing a course contrary to depriving the bees the power to raise queens, or by introducing the alien queen before the proper time had elapsed tending to safe introduction, and by following plans recommended by some as safe methods. He said there was a great difference in introducing a queen to a hive that had been queenless for a time from one that had been but recently deprived of their queen for the purpose of introducing one of a different race. With the former there was no risk, but with the latter there were. Referring to the different races of bees, Mr. Paterson said he kept none but the old black variety; that Ligurian bees would not fill supers with him. Mr. Thomson said that the greatest takes of honey he had had were from Ligurians, but he found they

required special treatment, that all Ligurians were not of the same excellence. In this case beauty went along with industry, but he failed to see how Mr. Paterson had the pure British bee when he had the Ligurians. He had no doubt the dark colour might be preserved, but he believed the excellent character he had to give of the original black bee was due to the fact that the Ligurian blood was imbued in them. As to the different races of bees, he had had seven years' experience with the Carniolians, and during all that time had not experienced any fault; they were mild-tempered, vigorous—particularly the drones—great honey gatherers, and very prolific. They were great flyers, going further than any other variety. He could strongly recommend them to any person. Their only fault was their flying far and long at swarming time, and particularly so with second swarms.

TRADE CATALOGUES RECEIVED.

Viccars Collyer & Co., Central Hall, Leicester.—*Lists of Specialities.*
James Dickson & Sons, Newton Nurseries, Chester.—*Catalogue of Forest and Ornamental Trees, Underwood Plants, &c.*
W. Drummond & Sons, 58, Dawson Street, Dublin.—*Catalogue of Forest, Ornamental, and Fruit Trees, Roses, Shrubs, &c.*

* * All correspondence should be directed either to "THE EDITOR" or to "THE PUBLISHER." Letters addressed to Dr. Hogg or members of the staff often remain unopened unavoidably. We request that no one will write privately to any of our correspondents, as doing so subjects them to unjustifiable trouble and expense.

Correspondents should not mix up on the same sheet questions relating to Gardening and those on Bee subjects, and should never send more than two or three questions at once. All articles intended for insertion should be written on one side of the paper only. We cannot reply to questions through the post, and we do not undertake to return rejected communications.

Hyacinth Holder (J. S.).—The instrument seems well adapted for the use mentioned, but we think we have seen lighter and more elegant contrivances.

Address (E. T. H.).—Mr. Osman's address is, as was published in the report of the Crystal Palace Show, Southern Metropolitan District School, Sutton, Surrey.

Seedling Lapageria (J. Garrett).—The flower is very good, both in substance and colour. Many seedlings have been raised by crossing the red and white forms, and varieties raised more or less like your own, which is not sufficiently distinct to have any special value.

Fruit Trees in Perforated Pots (N. H. T.).—If you have had no experience in growing fruit trees in pots we must decline the responsibility of advising you to erect houses for growing fruit in the manner indicated as a profitable investment. You cannot get better information on the subject of growing fruit under glass in any book cheaper than the one published by Mr. Rivers. The price of Dr. Hogg's "Fruit Manual" is 16s., post free 16s. 9d.

The Nanny Apple (Inquirer).—There certainly is an Apple of this name and a very good autumn dessert fruit it is. It is medium-sized, 2½ inches wide, and 2½ inches high; roundish, narrowing towards the apex, and somewhat angular on the sides. Skin smooth, greenish yellow with broken streaks of red on the shaded side, but bright red, streaked with dark crimson, on the side next the sun; the whole strewn with russety dots. Eye open, with flat segments, placed in an angular basin, which is marked with linear marks of russet. Stalk short, inserted in a rather deep, round cavity, thickly lined with rough russet, which extends in ramifications over the base. Flesh yellow, rather soft and tender, juicy, sugary, and highly flavoured. It is in use during September or early October, but soon becomes mealy. The tree attains the middle size and is a good bearer, much more so than the Ribston Pippin, to which the fruit bears some resemblance in flavour.

Catherine Pear (L. P.).—The description of this Pear which you require is as follows:—Fruit small, 2 inches wide, and 2½ inches long, pyriform. Skin smooth and shining, fine clear yellow, with a blush of red streaked with darker red on the side next the sun. Eye small and open, set even with the surface. Stalk three-quarters of an inch long, inserted on the apex of the fruit without depression. Flesh firm, fine-grained, very juicy and sweet, but soon becomes mealy. An early Pear, ripe in August. This is an old English Pear mentioned by Parkinson in 1629.

Bulbous Irises (J. T.).—You may plant them at once where the plants are intended to flower, taking care that the land is well worked, so that superfluous water can pass freely away. It is better to draw drills of the requisite depth or make excavations if you desire to plant in clumps than insert the bulbs with a dibber. They should rest on a light base, plating under and around them sand or other gritty matter. If you wish to have a bed of these Irises the bulbs may be placed 6 inches apart; if you desire

to have them in clumps in mixed borders half a dozen bulbs should be planted in a circle 5 or 6 inches in diameter, and they may be covered 2 or 3 inches deep with light soil. The flowers are very bright and beautiful.

Apricot Failing under Glass (J. T. H.).—Apricots when grown under glass require an abundance of air in spring or when flowering, so as to keep the atmosphere buoyant and dry. This, we think, is the cause of the failure in your case—viz., the house is kept too close, too moist, and too high in temperature at the time of flowering, which brings on the flowers too quickly, they being then puny, and the blossoms do not set and fruit swell, simply because not fertilised. The only remedy is to give more air, keeping the house cooler and drier. A few degrees of frost will not injure the blossoms providing they are dry, but it as well to exclude it, and especially from the embryo fruit, which is very tender. This course of treatment will of course interfere with the Peach trees to some extent, but if you want Apricots they must have air, as a close atmosphere is fatal. Perhaps the tree suffers by want of water at the roots during the resting period. The soil should be kept moist at all times, and care should be taken to have it thoroughly so when the buds are swelling and onward throughout the period of growth.

Planting Slopes on Limestone (W.).—Beech does admirably on limestone or chalk, and we should make it exclusively the hard wood throughout. We have also seen some very fine plantations of Larch on limestone where the soil was thin and bouldery, the Larch having to be planted in the crevices or spaces between the boulders. These would make capital nurseries for the Beech, and prove profitable after the first few years from the necessary thinning. Scotch Fir also does capitally, and is an excellent nurse; but it ought to be used less—more sparingly than Larch, from its not being nearly so valuable as timber. A few Austrian Pines may be used, but chiefly on the outside, for the sake of effect and shelter. Corsican Pine is quick-growing, and may be put at the back, especially where you have deeper soil. It is a very handsome tree, always telling well in a mixed plantation from its deep green foliage and towering habit, usually rising above them all. By all means trench the ground—a process too much neglected—as the best means of securing the speedy establishment of the trees and certainty of securing a good growth. Manure will not be necessary unless the ground is poor and devoid of fibrous matter, as that of turf or a grassy surface. If manure be given it should be thoroughly decayed, as Conifers do not do well in soil containing crude manure.

African Groundsel (Reader).—It is quite true this name has appeared in the Journal. It is employed in connection with a somewhat remarkable climbing or trailing plant—*Senecio macroglossa*, which is figured on page 67, vol. viii., January 24th, 1884. It is described there as having leaves like Ivy and flowers resembling those of the *Etoile d'Or* variety of *Chrysanthemum frutescens*. *Senecio macroglossus* has been found on the Table Mountain, at the Cape of Good Hope, and in other districts of South Africa, seeds having been first sent to Kew by Mr. Sanderson in 1868, and from these probably the first plants grown in this country were raised. Sir Joseph Hooker states that he has heard that in some continental or other cities this plant is grown in rooms and trained round the walls near the ceiling, and from its peculiar succulent structure it would, no doubt, be fitted for such dry positions, though its strength would be severely tested in ordinary English rooms. The best position for it is a greenhouse or cool stove, but the former is preferable, as it cannot endure a moist atmosphere. It is not particular as to compost, light sandy loam with a little leaf soil or old decayed manure being suitable, and if grown in a pot this must be thoroughly drained and water very carefully supplied. The best plan is, however, that adopted at Kew, where it is planted out and trained up the roof of the house.

The Rationale of Planting and Potting Bulbs (E. S.).—You ask for "information on the rationale of bulb-planting in the open border and in pots," and observe that "neither Lindley's 'Theory and Practice of Horticulture' nor Thompson's 'Gardener's Assistant' throw much light on the matter, especially as to the depth at which bulbs should be planted to secure complete success." Something more than the mere depth that bulbs are covered is requisite for achieving complete success; still, we will endeavour to answer your question. The bulbs of the splendid Hyacinths that are awarded honours at the London shows are scarcely covered, but the apex of such is about level with the rim of the pot, and the surface of the soil is made level fully half an inch below it. The same remark applies to Narcissi, Tulips, Crocuses, Scillas, and small bulbs generally are just covered with soil when grown in pots, and the pots in turn covered about 5 inches deep with cocoa-nut fibre refuse. This applies to all bulbs. In planting bulbs in beds for one season only—that is, removing the bulbs after flowering—they are covered a little more than their own depth with soil. Crocuses, for instance, are covered a little more than an inch deep, and Hyacinths twice that depth, about an inch thick of fibre refuse or leaf mould being spread on the beds after the soil is levelled over the bulbs. In planting bulbs in borders to remain permanently they should be covered from twice to thrice their own depth or thickness—Crocuses and the like 2 to 3 inches, Hyacinths and the like 4 to 5 inches. If planted near the surface the earth is washed from them sooner or later. But it is bad practice to simply press a dibber into the ground to those depths and drop the bulbs into the holes thus made, as they are then either suspended or rest on a hard base, and in adhesive soil these holes are really miniature wells in which water collects. The base on which bulbs rest should be light and free—roots then penetrate it readily and superfluous water passes away. Bulbs should also be covered with soil through which the growth can extend freely, and the lighter it is the deeper they may be covered—for instance, they will push through 6 inches of leaf soil or gritty vegetable matter with greater freedom than through 2 inches of clay. It is an excellent practice to embed bulbs in and surround them with sand, or a mixture of sand and wood ashes, and too much importance cannot be attached to early planting. The more the crowns extend from bulbs out of the ground the worse it is for them, and root-extension should be slightly in advance of top growth for securing "complete success." Your letter would have been answered last week if it had been received a day sooner.

Names of Fruits.—The names and addresses of senders of fruit to be named must in all cases be enclosed with the specimens, whether letters referring to the fruit are sent by post or not. The names are

not necessarily required for publication, initials sufficing for that. (*Rev. C. Marsden*).—1, Beurré d'Arenberg; 2, Passe Colmar; 3, Chaumontel. (*D. I.*).—1, Swan's Egg; 2, Suzette de Bavy; 3, Belle Julie; 4, Beurré Diel; 5, Spanish Bon Chrétien. (*J. S.*).—Pears: 1, Comte de Lamy; 2, Seckle; 3, Easter Beurré; 4, Noveau Poiteau. Apples: 1, Bedfordshire Foundling; 2, Wyken Pippin. (*W. L.*).—Seckle Pear. You will see a history of it in "The Fruit Manual" (*J. C.*).—1, Dumelow's Seedling; 2, Sturmer Pippin; 3, Norfolk Beefing. (*W. Hull*).—1, Golden Noble; 2, Crimson Queening; 3, Bleuheim Pippin; 4, Marie Louise; 5, Winter Nelis; 6, Josephine de Malines. (*J. Cornhill*).—Marie Louise d'Uccle. (*E. M.*).—1, Northern Greening; 2, Winter Colman; 3, not known; 4, a small Van Mons Leon Leclerc; 5, not known. (*H. H.*).—1, Gloucestershire Costard; 2, Wiltshire Defiance; 3, Beurré Diel; 4, American Mother. 5, Pitmaston Duchess; 6, Beurré Diel.

Names of Plants.—We only undertake to name species of plants, not varieties that have originated from seed and termed florists' flowers. Flowering specimens are necessary of flowering plants, and Fern fronds should bear spores. Specimens should arrive in a fresh state in firm boxes. Slightly damp moss or soft green leaves form the best packing, dry cotton wool the worst. Not more than six specimens can be named at once. (*W. A. Kenning*).—1, *Agrostemma Flos-Jovis*; 3, *Armeria maritima*. We cannot name the others from such specimens.

Square Stewarton Hive (Zenas).—You will find that the square "Lanarkshire" divisional hive with ventilating floor, as described lately in these pages, approaches nearest to the Stewarton proper, and is better adapted, with all the later improvements, to bee-keeping than any other form of the square Stewarton type. It may be had from Messrs. George Neighbour & Sons, 149, Regent Street, London. We are not able to say where you can procure an African goat.

COVENT GARDEN MARKET.—NOVEMBER 11TH.

TRADE very quiet, with heavy supplies. Large arrival of St. Michael Pines this week. Kent Cobs very dull.

WINTER DIET.

To the practical home farmer, for whom our notes are written, the term "dairy cows," as used in our last article has a special significance, meaning, as it does, cows devoted solely to the production of milk, cream, and butter—aye, and cheese too, if you will, but not to the rearing of calves. We altogether object to the state of semi-starvation in which calves are so frequently kept; the system is radically wrong, and one would suppose that the most ignorant person would see the folly of it. Kept without food from ten to twelve hours at a time, faint from sheer exhaustion yet frantic with hunger, the calf rushes eagerly to the cow and gorges itself to repletion, and so the first few weeks of its existence are spent in a regular series of alternations of hunger and gluttony. Can we wonder that this unnatural treatment so frequently causes delicate calves to suffer from acute diarrhoea, to which many of them succumb and die?

Surely common sense should tell us that every calf, whether healthy or sickly, strong or delicate, requires three or four meals daily. The reason given for keeping calf and cow apart is to save the milk, and it is easily understood how valuable the rich milk of a Jersey or Guernsey cow is. If it must be had for the dairy, then why not let the calf be taken altogether away from it, and let it have a foster mother? One of the most pleasant and instructive sights we have met with of late was that of two fine polled Suffolk cows, each with a pair of calves constantly with them, cows and calves all being in high condition. This is an admirable method of rearing calves for the dairy herd.

Upon most large home farms two distinct herds of cows are now kept—the dairy herd and the stock herd. For the latter purpose we select either pure-bred Sussex, polled Suffolks, Herefords, Devons, or Shorthorns—big square-built yet compact fleshy animals that ripen early for the butcher. In this herd there are no milk pails, no dairy, the calves always running with the cows and sucking till the cows are dried for the next calving. In Mr. Henry Evershed's valuable little work on "The Early Maturity of Live Stock" we are told how this treatment "Made a grand job of the calves. At the age of eleven or twelve months they were not only big stocks, but very fat—not veal, but the firmest of beef. The calves shared with their dams the summer keep of good grass and the winter fare of meadowhay, roots, straw, cake, and grain. To make way for the newly dropped calves the yearlings were sold to the butcher at from £20 to £24 a head, representing nearly £2 per head per month's keep." The articles of diet enumerated as winter fare are by no means despicable. We would give some of the fodder as chaff, adding to it a moderate quantity of crushed linseed and linseed meal at the rate of 1 lb. to a gallon of water and boiled to a jelly. This mixture is wholesome both for cows and calves. It tends to check any tendency to scouring in calves, and it is also fattening. The home ground or crushed linseed contains 17 per cent. of digestible albuminoids and 32 per cent. of fat, while the linseed meal of commerce from which the oil has been extracted contains 28 per cent. of digestible albuminoids and only 2 per cent. of fats, for which reason it is considered preferable for young animals. Oilcake should be selected with care, and always subject to analysis, quite two-thirds of cake in the market being adulterated. Very hard dry cake may be genuine, but it is indigestible unless it is ground, crushing in the ordinary way being insufficient. We can strongly recommend Waterloo round cake as genuine cake, and quite the best we have tried. Small quantities of cake may be tested at home in this way—Grate a piece of cake with a kitchen grater, which leaves bran and extraneous seed unaltered; or mix half an ounce of cake with 5 ozs. of water. If good it forms a stiff jelly, agreeable to smell and taste; if bad, it has a disagreeable odour, and it contains a large mixture of seeds of *Commelina sativa*, which are much too acrid for cattle. If bran and sand have been mixed with the crushed linseed the water test will set free both, the bran floating upon the surface and the sand sinking to the bottom.

Under the present strained conditions of farming a large outlay on oilcake is a questionable step. We ought certainly to turn home-grown corn to account for the stock herd, and by judicious mixing impart a wholesome variety to the food. Far better is it to do this than to sell the corn at a loss and buy cake also at a loss. Rather avoid cake; use mixed corn and linseed jelly mixed with chaff. But beware of pressing on young stock too fast; there is a safe mean at which we ought to aim. Setons in the dewlap, a rather large proportion of roots and Cabbage in the mixed diet, are our safeguards, and our use of such cool, wholesome, juicy foods must be persistent if we would not run the risk of a heavy loss of our young best stock. Where silage can be had it ought certainly to enter largely into the mixed diet of our stock herd, for here we have no trouble about flavour of milk; rather do we aim at the promotion of a full strong

flow that is quite certain to prove nourishing for the calves. Certainly, if any profit is now to be derived from rearing and fattening live stock it must be done in the manner we indicate. There must be both quick lusty growth and quick returns for our expenditure.

(To be continued.)

WORK ON THE HOME FARM.

The pulling, cleaning, and storage of root crops is being done as briskly as weather admits, so much rain having fallen recently as to hinder work in the open fields, and to quite stop carting on heavy land. Swedes will now be cleared off most of the fields and put in heaps at convenient points easy of access, if possible near a gate or alongside a hard road. We intend holding part of our stock of Swedes in reserve for the breeding flock, and as the roots will not be required for that purpose till March we decided to take them off the land both to preserve the roots and to clear the way for ploughing. Hoggets will be folded upon Turnips; but this must be done with judgment, and not by line and rule. We find our habit of driving out to inspect off farms when convenient, without paying much heed to the weather, proves useful in many ways. A few days ago we did so on a wet day, and upon going out with the bailiff to the old sheep being fattened for market we found them in a fold upon Turnips, standing about in a mud puddle almost over our boot tops. We at once helped to drive those sheep into a spare yard with plenty of open sheds, and orders were given for the sheep to be put in the yard or out in the fold or upon grass, according to the state of the weather. All this involves more work, but it is quite worth while, even from a money-making point of view; and we cannot too often repeat that exposure to cold and wet makes demands upon the health and condition of animals which can only be met by the consumption of an extra quantity of food. The storing of Cabbages in winter is a matter of considerable importance, which, if successful, enables us to keep cattle in yards supplied with this wholesome article of diet till the Thousand-headed Kale is ready. In a recent number of the *Agricultural Gazette* we saw the following simple and what was termed successful plan of doing this:—"Throw up a sort of land or ridge with the plough, and make it pretty level on top. Upon this land lay some straw, then take the Cabbages, turn them upside down, and, after taking off all decayed leaves, place them about six abreast upon the straw; then cover them, not very thickly, with straw or leaves raked up in the woods, throwing here and there a spadeful of earth on the top to keep the covering from being blown off by the wind. Only put on enough of straw or leaves to hide all the green, leaving the Cabbage roots sticking up through it.

"Stored in this way Cabbages of all sorts will be found to keep perfectly good and fresh until April and May, or even later. Not only do the Cabbages keep better in this than in any other way, but they are at all times ready for use. They are never locked up by frost, as often happens with those pitted in the earth; and they are never found rotting, as is often the case with those which are laid with heads upwards and their roots in the ground. Savoys, which are at once the best in quality to keep of all winter Cabbages, may be stored in the same way."

THE COST OF BURNING BALLAST.—My statement that it costs a shilling a yard to burn ballast was made on the hypothesis that draining operations were going on, in which case the clay would be provided ready dug as a matter of necessity by the drainers. Most working men are very wasteful and ignorant; they use thrice as much coal as there is any necessity for. With proper management a ton of small coal will burn at least ten yards of ballast. A working man will want two tons, but in this case the eye of the master will be worth the other ton. I shall be glad to give further information on this subject in answer to any inquiries that may be addressed to the Editor.—W. M.

REMARKS.

- 1st.—Very fine day; misty evening.
- 2nd.—Fine bright day.
- 3rd.—Dull morning; wet afternoon; fair night.
- 4th.—Continuous rain till 4 P.M., then cleared up, cloudless night.
- 5th.—Fine till 10.30 A.M., then showery till 1 P.M.; fine and bright after.
- 6th.—Fine bright day; hazy evening.
- 7th.—Thick morning and cloudy day.

A rather changeable week, but on the whole of about the average temperature.
G. J. SYMONS.

PROPOSED INTERNATIONAL HORTICULTURAL EXHIBITION IN 1887.

WE published last week a series of resolutions of an important character that were passed at an influential meeting of botanists and horticulturists, pertaining to a subject in which the vast majority of our readers are more or less interested. The first resolution is a declaration of the desirability of holding an International Show and Congress of Horticulture in its widest sense, and indicates an appropriate time—the jubilee year of Her Majesty's accession to the throne—for carrying out the project. The second resolution records what is considered the most advantageous site, which is, we presume, that known as the Royal Horticultural Society's Gardens at South Kensington, the property of the Commissioners of the Exhibition of 1851, subject to a proviso that the rest of the grounds be not incongruously occupied at the same time by the Commissioners. The third resolution requests the President and Council of the Royal Horticultural Society to ascertain the views of the Commissioners on the matter, and embodies an assurance that if the proposals of the Commissioners are of such a nature as to afford reasonable hope that the Show and Congress may be carried out in a manner worthy of British horticulture, no effort shall be wanting on the part of horticulturists to secure the success of the undertaking.

As to the desire for an exhibition of the nature indicated, that has long existed; but the time for holding it has not hitherto been declared with sufficient unanimity. The desire is now emphasised, the time accepted, and the site approved. The year 1887 promises to be historical, and the gardens to which millions "know their way" must, or should, be utilised during that year if the continuity of public interest in them is to be maintained. It is hoped, therefore, that the Commissioners will make proposals of an encouraging nature that shall be of mutual benefit to themselves as custodians of the property, to the great industry of horticulture, and to the public, who may derive pleasure and instruction from an inspection of the products of the soil in their ornamental and useful aspects.

An idea appears to prevail in the minds of not a few excellent but enthusiastic individuals that the Royal Horticultural Society should undertake the responsibility of a work of this kind. This is not practicable. That Society was not responsible for the Exhibition of 1866. The responsibility of its success or failure rested with the subscribers to and guarantors of the exhibition fund; and so it must be again if the much greater project contemplated be carried out. The Royal Horticultural Society will undertake the practical governance of the proposed undertaking, and will leave nothing in its power undone to contribute to its success; but we are bound to say it will in a very great measure depend on the Commissioners as to whether the great Exhibition so much desired can be held on their property or not.

We have no doubt whatever that the international resources of horticulture and vegetable products are adequate for the maintenance of an exhibition of commanding interest over a long period; but we have never felt that the whole of the vast space occupied by the exhibitions of the past three years at South Kensington could be satisfactorily furnished as a mere flower show, and with other garden produce. The meeting of last week appeared to be of the same opinion, hence the reference to the occupation of the "rest of the grounds" by the Commissioners. The Exhibition, to be successful, must be on a gigantic scale, and much wider in its scope, far more varied, interesting, and instructive than any mere display of flowers can be, and the whole resources of horticulture, forestry, and agriculture must be requisitioned to achieve a success commensurate with that of the shows of the past three years.

We discussed the question of an International Horticultural Show in 1883, and then published what in our opinion should be the lines on which such an exhibition should be founded. We said then, and repeat now, that it should embrace as far as possible the whole products of the vegetable kingdom—condensed by a correspondent at the time into a "Vegetable Kingdom Exhibition." What we propose, then, is that there should be an exhibition of horticulture, forestry, and vegetable products. The main body of the Exhibition would consist of the two latter. In forestry we should have not only illustrations of the subject as it is practised in this country and the other countries of Europe for the supply of timber for commercial purposes, but that it should embrace representations of all the woods of the natural forests of the United States of America, our own colonies, India, China, Japan, and of the governments of South America; specimens of the timber cut and polished, and transverse sections of the trees. Living trees of the forests of temperate regions might be planted in the open grounds of the garden, the seeds and fruits could be shown in the galleries along with the woods, and the living plants of tropical trees could be shown in a house specially set apart for them. Every manufactured product of these trees might also be illustrated.

Then there are the plants cultivated for their fibre—Hemp, Flax, Cotton, Jute, China Grass. There might be not only illustrations of the plants in all their stages, but also of the industrial element. What more interesting than to see an Indian at his loom weaving Dacca muslins; the various processes for the preparation of cotton from the pod to the spinning jenny; the hemp industry; a rope walk, and the making of twine; straw plaiting, and the employment of straw, esparto, and other fibres in the great paper-making industry; food products, such as cereals, and their methods of preparation from the mill to the oven; pulse, and their products of herbage and forage; plants for supplying beverages, and methods of preparation—tea, coffee, cocoa, wines, hops, beer; starch, and its preparation from rice, potatoes, wheat, &c; also arrowroot, cornflour, and articles of this nature in use by the million, but of their origin and preparation the million are practically ignorant; plants furnishing the materia medica, with specimens of the drugs, and information relative to the sources from which they are drawn and how obtained; tobacco—the manufacture of cigars in operation; sugar, with examples where practicable of preparation from cane and beetroot; preserves and pickles—the various methods of preparing fruits and vegetables could be fully represented, and the magnitude of this industry exemplified; plants cultivated for their uses in the arts—caoutchouc, gutta percha, with the manufacture of water-proofs represented; also plants cultivated for their oils, dyes, perfumes, and tanning, with examples of obtaining and applying their products.

This is a hurried outline sketch of our project, but we believe it is sufficient to show that it will form a strong and sure basis for an exhibition of far-reaching interest and

importance. Add to this the appliances in connection with forestry and horticulture, tools, machinery, structures, methods of heating and every adjunct in connection with woods and gardens, models of roots and fruits, cones, seeds, also zoological museums of beasts, birds, and insects as friends or enemies of the cultivator. Nor would we overlook the curiosities of vegetation. From the museums in this country, and with examples from foreign lands, we feel sure that a collection of objects of a very extraordinary nature could be arranged that would be a source of great attraction to visitors.

With the same agency that has worked so effectively in producing the past exhibitions at South Kensington, at least equally great results might be achieved in carrying out this project. Through the Colonial and Foreign Offices every country would be reached, and every country would be ready to represent its staple industry obtained from vegetable products, while each having its court and native workers, would powerfully attract attention to its own industry, a vast area of buildings would be filled without difficulty, and an exhibition of extraordinary interest and irresistible attractiveness would be produced.

Nor would all this in the slightest degree detract from the extent or beauty of the exhibition or exhibitions of plants and flowers. We can see no obstacle whatever to holding periodical exhibitions throughout the year, and one of them, say in June, to be as rich and on as large a scale as that of 1866, provided sufficient inducements are provided to bring the best examples of culture together at a given time. For instance, a magnificent exhibition of Azaleas, Rhododendrons, and Roses in pots could be provided in early May; then a gigantic miscellaneous exhibition might be held in June, with an international jury of adjudicators, who could be entertained on the 20th, which will be a general "banqueting day." The Pelargonium and National Rose Shows would follow in July; in August the National Carnation, with a second miscellaneous plant and early fruit show on an extensive scale would command attention, as would the succeeding Dahlia and General Cut Flower Show in September. A Potato and Root Show would be a success in October. Then the campaign might be brilliantly closed with a Chrysanthemum and Hardy Fruit Show in November. In this way horticulture would be more fully represented than by any other means, and an ever new and ever widening panorama of attractiveness would be unfolded. Besides and between these shows nurserymen and growers of plants for market might presumably occupy space with Clematises, Pelargoniums, Roses, Rhododendrons, fruit, &c., and thus in some measure a continuous display would be produced to brighten what, if well carried out, would be the most complete exemplification of the resources and importance of the vegetable kingdom ever seen in any country.

As at the exhibition, the Vegetarian Society would no doubt be glad to provide cheap dinners, nutritious and toothsome, composed wholly of vegetable food; and it will be conceded that instruction on the best methods of preparing vegetables and fruit for culinary purposes is as much needed as the popularisation of fish as an article of diet. This aspect of the case demands, and will no doubt receive, consideration.

There is hope now that the great Exhibition contemplated will be held, and we have only to add that the sooner a decision is arrived at and the necessary machinery is put in motion the better. The undertaking will be a gigantic one, but the same energy that has been displayed in preparing for and providing the great Exhibition of the present year will be fully equal to the task of providing another exhibition—essentially different, and certainly of not less public importance—in 1887.

NEW CHRYSANTHEMUMS.

NOVELTIES amongst Chrysanthemums, especially of the Japanese type, have been numerous shown this season, and some have come

to the front so well that they will probably take a place amongst the standard exhibition varieties. Every grower likes to add some of the best new varieties to his collection each year, and to aid in making a selection it is intended so name in the following notes a few of those which have been best shown at the London exhibitions, or which have appeared to best advantage in the trade collections. Before doing so, however, I wish to draw attention to an interesting essay on the Chrysanthemum by a French amateur Mons. Ghys, which contains some interesting matter in relation to the raisers of French varieties and dates of sending out which cannot be obtained in any English publication at present. A brief review of the history and culture of the Chrysanthemum is given, M. Ghys duly acknowledging the assistance he has received from Mr. Harman Payne, the author of the interesting "History of the Chrysanthemum" just published. Then a list of over 200 Japanese varieties is given, followed by much smaller and less satisfactory lists of Chinese, Anemones, and Pompons. It is dated June 1st, 1885, and includes the majority of this year's varieties, with brief descriptions. Of the older varieties few are given before 1880, and the great majority of the best exhibition Japanese forms have appeared since that date. I have selected from the list of Japanese some of the finest and best known varieties, arranging them under the names of their raisers, those from M. Delaux well meriting the foremost place. Several are omitted where the dates were not given in M. Ghys's essay, but a few are named without dates, as they are notable varieties. The selection from M. Delaux's varieties comprise over sixty, and probably he has distributed nearly 100 in the time named, some of which have never found favour with English growers.

VARIETIES RAISED BY M. DELAUX.—Alexandre Dufour, 1881; L'Aube Matinale, 1885; Beauté des Jardins, 1884; Beauté de Toulouse, 1882; Brise du Matin, 1884; Colibri, 1884; Enehantresse, 1886; Etoile du Midi, 1881; Fernand Féral, 1884; Flamme de Punch, 1883; François Delaux, 1882; General de Lartigue, 1882; Ile Japonaise, 1882; L'Ile des Plaisirs; L'Incomparable; L'Incroyable, 1884; Isidore Féral, 1882; Japon Fleuri, 1882; Jeanne Delaux (?), 1882; Jupiter, 1885; Læniata Rosea, 1885; Lakmé, 1885; Le Chinois, 1882; Madame Boucharlat aîné, 1881; Madame Cannell, 1885; Madame de Sevin, 1884; Madame Deveille, 1883; John Laing, 1885; Mdlle. Antoinette Brunel, 1884; Mdlle. Louise Sabatié, 1882; Mdlle. Mélanie Fabre, 1885; Margot, 1883; Mastic, 1883; Mons. Astorg, 1883; Mons. A. Vilmorin, 1885; Mons. Castel, Mons. Deveille, 1883; Mons. Ghys, 1885; Mons. Harman Payne, 1885; Mons. H. Jacotot, 1883; Mons. J. H. Laing, 1885; Mons. John Laing, 1884; Mons. Juan Cruz d'Eguileor, 1881; Mons. Moussillac, 1883; Mons. N. Davis, 1885; Mons. Léon Brunel, 1884; Mons. Plancheveau, Mons. Tarin, 1883; L'Or de France, 1884; L'Or du Rhin, 1883; Progrès Toulousain, Richard Laros, Rosea Superba, 1880; Rubra Striata, 1881; Simon Delaux, 1882; Souvenir du Caire, 1884; Souvenir de Haarlem, 1885; Souvenir du Japon, 1884; Source d'Or, 1882; Source Japonaise, 1882; Striatum Perfectum, 1881; Le Surprenant, 1884.

VARIETIES RAISED BY M. LACROIX.—Flocon de Neige, 1881; Gloire Toulousaine, 1883; La Nuit, 1879; La Pureté, 1880; Mdlle. Lacroix, 1880; Mdlle. Moulise, 1878; Mentor, 1880; Rosa Superba, 1880; Tendresse, 1881; Dormillon, 1882.

VARIETIES RAISED BY M. DE REYDELLET.—Carmen, 1884; Cendrillon, 1884; Cérés, 1884; Flamboyante, 1885; Flocon de Neige, 1885; La Triomphante, 1885; Madame de Reydellet.

VARIETIES RAISED BY M. MARROUCH.—Belle Paule, 1881; Madame C. Audiguier, 1879; Madame Emile Dufour, Marguerite Marrouch, 1878.

Amongst the Japanese are included several which we now place in different groups; for instance, Madeleine Tezier (de Reydellet) has been shown this season as an excellent reflexed variety by Mr. Molyneux, while Fabian de Mediana (1882, Lacroix) has taken its place as one of the best of the Japanese Anemones, though this season it has been so late in developing that the blooms at the earlier shows were by no means in character. There are many others included in the list that are unknown in cultivation in England, or are in so few collections that they are rarely seen. The English nurserymen have tried and discarded many of these, and only the best are preserved, for their merits or defects are soon perceived, and amateurs are saved much trouble and expense, for in such a large number of novelties as make their appearance from France every season there must necessarily be a good proportion of indifferent merit. Either the French growers do not exercise the same discrimination that specialists do in this country, or the varieties assume superior characters under their bright skies than they do in foggy England. In any case it is certain that the home nurserymen in selecting the most promising of each year's productions are doing an invaluable service.

In the list of Chinese varieties furnished by M. Ghys seventy-

three are named, mostly incurved, but some, as Julie Lagravère and Progne, are evidently out of place. This list is indeed a very imperfect one, both the raisers' names and the dates being omitted in numerous cases. The principal of the French varieties is Lacroix's Jeanne d'Arc, which was sent out in 1881. Mons. Viviani Morel, one of M. Delaux's 1885 novelties, has been shown on several occasions this season, and certificated at the Aquarium Show. It is more inclined to a reflexed form than an incurve, but the florets nearly erect.

Twenty-one "Chrysanthèmes Avéoliformes," or Anemone varieties, are named, of which we may mention Madame Berthie Pigny (Dr. Audiguier), Madame Clos (Marrouch), Mademoiselle Cabrol (1879, Marrouch), and Sœur Dorothée Souille (1877, Marrouch).

The new varieties which have made their appearance in England this season include several of sterling merit, while some that were introduced last year, such as Val d'Andorre and Belle Paule, have most deservedly won the admiration of numbers of growers, and nurserymen who make a specialty of Chrysanthemums may expect a large demand for them. Of the strictly new varieties those that have found most favour are all Japanese—namely, Lakmé, Jupiter, Madame John Laing, L'Aube Matinale, Mons. A. Vilmorin, Mons. Freeman, Mons. N. Davis, L'Adorable, Souvenir de Haarlem, Mons. Ghys, and Mandarin; the slightly older Brise du Matin and Margot also having received substantial recognition. The only incurved variety of any value that has been shown is Messrs. Carter's sport from Queen of England, appropriately termed Bronze Queen, which the National Chrysanthemum Society honoured with a certificate. A few early-flowering and other varieties have also been added, but to these and the preceding I must refer more in detail in some other notes.—LEWIS CASTLE.

ESTIMATES OF VEGETABLES.

ONIONS.

As a crop for market Onions are important, if, indeed it is not one of the most valuable from a paying point of view. The crop of course varies according to the season, the present one not being favourable, for though the crop was not a failure the dry weather so influenced it as to render the bulbs small—picklers being plentiful and cheap; added to this the larger-sized ones have not kept well, and large importations have kept prices down—the prices being at present 60s. to 90s. per ton. I have, however, no cause to complain, as I have 12 to 14 tons to the acre, and the salesman gets 4s. 6d. and 5s. per cwt., the Onions being fine, and such always command sale and bring the best returns.

The varieties of Onions are very numerous, but I think they may safely be divided into two sections, or those with flat crowns, and those raised or pear-shaped. The first as a rule attain the largest size, and are usually good keepers, as the flat or hollow crown seems to form a receptacle for water; and if the weather prove wet at the time of maturing, the bulbs decay at the neck, or become so saturated that they do not keep well after storing. The latter or pear-shaped, having the neck high, throw off the wet better, and they keep very much longer, indeed are the only sorts worth terming keepers. Flat Onions are those of the Spanish or Portugal type, and all are evidently of one stock; indeed, Nuneham Park, Reading, Banbury Improved, Rousham Park Hero, with others are selected forms of the White Spanish. I had those this year except Nuneham Park, and that I had grown it in former years and found it no improvement, in fact all these improved sorts lose their identity in a season or two.

Of the yellow Onions I have only grown two—viz., Danver's and Giant Zittau; they appear to be an admixture of the early white and brown varieties. Danver's Yellow I find a very bad keeper, and not nearly so good a cropper as White Spanish, but Giant Zittau I find a capital cropper and excellent keeper, a very valuable Onion, especially where there is an objection to brown varieties. These are flattish in shape, and evidently are intermediate between the White and Brown Spanish, only the Giant Zittau has more of the Globe shape, to which it perhaps owes its keeping qualities.

The oval or pear-shaped Onions are all of the Strasburg type, and are very variable. In the old Strasburg the bulbs are sometimes flat. It originated from the Spanish, but in the finest the oval form is prominent, and gives rise to the variety Deptford, which is marked by a paler skin; indeed, so nearly alike is this and Brown Globe that they may be placed in the same category, only I think Brown Globe by far the best form, as the bulbs have an oval shape and are better keepers. Perhaps the very finest of this section is Bedfordshire Champion, fine in form, capital in cropping, an excellent keeper and of the very best. Of the same class is the indispensable

James's Keeping, which as a keeper and quality late in spring is unequalled.

My selection therefore of summer Onions are White Spanish or any of its forms if expense of seed is no object, Bedfordshire Champion and James's Keeping. I have omitted Blood Red, as its flavour is not liked by the consumer.

Of the autumn-sown Onions there is none better for drawing young than White Lisbon, the bulbs come in quickly and sell well as bunch Onions. Early White Naples is also good for early bulbing and bunching, and of the Tripolis Giant Rocca is far the best.—UTILITARIAN.

BIXA ORELLANA—ANNOTTA.

It is from the shrub the foliage and flowers of which is now figured that the Annotta of commerce is produced. Plants are seldom seen in this country except in botanical collections; but they are not devoid of

Fig. 68.—*Bixa orellana*.

ornament by their fine green leaves and chaste pink flowers. When grown from seed the plants attain a large size before producing flowers; but when raised from cuttings they flower freely when in a comparatively dwarf state. Cuttings of half-ripened wood strike readily in heat under a bellglass. The plants require a summer temperature of 65° to 85°, and a winter temperature of 50° to 60°. This shrub grows spontaneously in South America, and is cultivated in the East Indies. The fruit is like a Chestnut, a two-valved capsule covered with flexible bristles, and contains a certain number of seeds smaller than peas. These seeds are covered with a soft, viscous, resinous pulp of a beautiful vermilion colour and unpleasant smell like red lead mixed with oil; and it is this matter which constitutes Annotta. The mode in which it is obtained is by pouring hot water over the pulp and the seeds, and leaving them to macerate until they are separated by pounding them with a wooden pestle. The seeds are then removed by straining the mass through a

sieve; and the pulp being allowed to settle, the water is gently poured off, and the pulp put into shallow vessels, in which it is gradually dried in the shade. After acquiring a proper consistency it is made into cylindrical rolls or balls, and placed in an airy place to dry, after which it is sent to market. This is most common in the English market, and is in the form of small rolls, each 2 or 3 ozs. in weight, hard, dry, and compact; brownish without and red within. The other process of manufacture is that pursued in Cayenne. The pulp and seeds together are bruised in wooden vessels, and hot water poured over them; they are then left to soak for several days, and afterwards passed through a close sieve to separate the seeds. The matter is then left to ferment for about a week, when the water is gently poured off, and the solid part left to dry in the shade. When it has acquired the consistency of a solid paste it is formed into cakes of 3 or 4 lbs. weight, which are wrapped in the leaves of Arundo or Banana. This variety is of a bright yellow colour rather soft to the touch, and of considerable solidity. Labat informs us that the Indians prepare an Annotta greatly superior to that which is brought to us, of a bright shining red colour, almost equal to carmine. For this purpose, instead of steeping and fermenting the seeds in water, they rub them with the hands, previously dipped in oil, till the pulp comes off and is reduced to a clear paste, which is scraped off from the hands with a knife, and laid on a clean leaf in the shade to dry. Mixed with lemon juice and gum it makes the crimson paint with which Indians adorn their bodies; and they employ the leaves and roots in cookery to increase the flavour and give a saffron colour.

Annotta is principally consumed by painters and dyers; but it is also used in Cheshire, Gloucestershire, and North Wilts to colour cheese with the pale yellow or flesh colour which distinguishes that which is made in these districts, the makers in Cheshire using 8 dwts. to 60 lbs. of cheese; while those of Gloucestershire use 1 oz. to 1 cwt.—quantities which are too small to affect the cheese in any way except in colour. The Dutch use it for heightening the colour of their butter. It is used for the same purpose in some English dairies.

PLANTING EVERGREENS AND FOREST TREES.

THOUSANDS at the present time are either engaged in or about to commence this operation, which cannot be regarded otherwise than one of the most important connected with gardening. The evil effects that result from planting injudiciously and bad management of the plantation afterwards, is painfully visible in too many gardens, and a note of warning at this period may be seasonable.

Planting and the management of the plantations afterwards are in a measure so closely connected that it is impossible to consider them separately if trees, plantations and shrubbery borders are to prove in the future ornamental and interesting. It matters very little what care is taken at planting, or what striking objects it is intended shall eventually be displayed, if the plantations are not attended to afterwards, for upon this entirely depends whether the end in view is ever attained. Good planting with thoughtful care in after management will result in the development of noble symmetrical specimens, each possessing characteristic features of interest and beauty. Badly managed plantations and shrubbery borders produce exactly the contrary—a confused mass of vegetation struggling for existence. For a time crowded luxuriant vegetation may appear beautiful to all, but an experienced man at once discerns the work of destruction that is going on, and knows only too well that the whole will be ruined in a few years. The better the preparation at the commencement, and the more robust their growth, the sooner they are bare and unsightly and fit only to be cut down and the ground replanted.

Plantations and shrubbery borders should be attended to annually, unless severe thinning is practised, and all trees and shrubs thinned out that are likely to crowd those to be retained for the future ornamentation of the grounds. Every tree or shrub that will interfere with the proper development of these should be lifted and planted elsewhere. This is not always practicable, and in some instances not desirable, for it depends whether those planted to fill up are really worth lifting. They can, however, be cut back by degrees, so that a great gap is not caused until they can be spared altogether. It is much better to sacrifice all that are not wanted, whatever they may be, directly they are becoming crowded, than allow them to grow together to the destruction of all. Gardeners are not wholly to blame for the neglected condition in which shrubbery borders and plantations are seen. Employers often object to the removal of a tree, or even a branch, and in consequence the whole soon goes to ruin; but I am inclined to think that if the importance of timely thinning was properly explained to them they

would soon see the value of such work, as I have proved to be the case in more than one instance.

When planting is done about the pleasure grounds it is often necessary to plant more closely at first than need be the case in other positions, so that a furnished appearance is presented at once. Under these circumstances mistakes are often made, and when the trees want more room the whole must be turned over, for thinning cannot well be done in any other way if due provision was not made at the commencement. The future even in these cases must be considered, and the plants so arranged that thinning when required can be done readily and easily without having to lift those plants that are intended to develop into specimens to furnish the space planted. When the whole have to be re-arranged the plants are checked and growth for a year or two at least rendered less robust. It is necessary in many instances to avoid this, especially when an endeavour is made to grow the plants into specimens as early as possible. When planting, say, a clump of Hollies it is wise to dispose the principal plants where they are to remain sufficiently far apart that they can attain full size without having to be removed afterwards. The space between them can be filled with similar plants or others to be relifted and planted elsewhere as the permanent plants develop. After these are removed those intended to remain will have attained some size, and the ground between them can be levelled and sown with grass seeds, if this can be done to improve the view or appearance of the ground. If not, and the plantation looks thinner than it is desirable to have it, a few smaller plants can again be placed for a season or two. Bulbous and herbaceous plants may occupy the ground for a time.

Something more than merely digging a hole, putting the roots of a tree in it, and then covering them with soil is needed. Planting with a view to the trees developing into grand specimens necessitates a thorough knowledge of the tree or shrub to be planted; its natural habit of growth, the size under favourable conditions to which it will attain, must be taken fully into consideration. Many mistakes are made through insufficient knowledge of these matters, and also for the want of knowing the surroundings and conditions under which trees, shrubs, and Conifers are displayed to the best advantage. The last is really a matter of observation rather than practice and experience, for much valuable information can be gained by observing the conditions and position under which certain deciduous trees and evergreens look most beautiful. My advice to young gardeners is to note particularly these matters, for the information so gained will prove invaluable to them in the future when the responsibility of this work devolves upon them. It may save many blunders which a lifetime afterwards would prove perhaps insufficient in which to rectify them.

Whether clumps of trees are planted for immediate effect or not, it must be duly considered before planting what deciduous trees and evergreens, if associated together, are to remain to become fully developed for permanent objects. If the ground is sufficiently large to accommodate one common and one Purple Beech, two Chestnuts red and white, a scarlet and a white Thorn, and two Laburnums, when fully developed, and these are the trees it is desirable to associate together, they should be so disposed on the ground that a distinct feature can be observed from as many points as possible. These main trees must not be planted a few yards only, but the size to which each will attain as they approach maturity should be considered and the plants arranged accordingly. A greater space still must be allowed if it is intended to have specimens Hollies, Pines, and Conifers amongst them. This system where practicable should be followed, for the one displays wonderfully the advantages of the other at the different seasons of the year. The evergreens give a furnished appearance during the winter months when deciduous trees are destitute of foliage. After the main plants have been arranged the remaining ground, if planted at first in the forms of clumps or plantations, can be filled with Sycamores, Privets, Rhododendrons, or any others that the planter may desire to be lifted out or cut down as the main trees require room for extension. Perhaps one of the greatest mistakes in planting is the association of forest trees and evergreens. How frequently do we find narrow belts or small plantations with two or three rows of forest trees, and the front formed with a row of Hollies, Rhododendrons, and others. These may look well while they are young. The front row or two of evergreens may be expected to make reasonable progress; but in a few years the strong ones at the back rob the ground of its fertility, and the smaller slower-growing plants fail to make headway, and soon become bare at the base. At first the evergreens are planted for the purpose of blocking out the interior of the clump, but soon fail to do so through being robbed of sufficient food, partially excluded from light, and subjected to drip from the trees in the background. This system of planting cannot be too strongly condemned, for in the end it is sure to prove disappointing.

Although I have advocated the association of ornamental deciduous trees and evergreens together, it is only when the two can be planted with plenty of room for the development of each without the one robbing the other of the necessary materials requisite for development. Plantations can be made of forest trees with evergreens in the front, and very beautiful and effective they are if planted right at the commencement and duly attended to afterwards. It is essential to accomplish this to keep the former well in the background, which in narrow strips as alluded to above cannot be done. The tallest trees should be planted in the centre of a large clump, or well in the background. If the former, an evergreen front may be presented all round, the latter being followed when only one front of evergreens is required. It may be supposed that the centre trees are Sycamores or others of similar growth, while to the front of these trees of a smaller size should be planted, such as some of the varieties of Mountain Ash, Thorns, Laburnums, and other trees of moderate growth. In the front may be planted evergreen Privets, and few plants form a better background for other evergreens, or are more beautiful when laden in summer with their deliciously fragrant trusses of white flowers. Privets deserve planting more largely as flowering shrubs when the system of planting I am attempting to illustrate is practised, for they suffer less by association with forest trees than any other evergreen. In good soil they grow rapidly, and soon form large bushes. To the front may be planted Silver Hollies, and in the angles hybrid or other Rhododendrons. This example is only one of many that could be given of planting clumps of deciduous trees and evergreens together, where the last-named would flourish and answer the purpose for which they were planted. This in a large measure depends upon judicious thinning after planting. The Privets, as well as the other evergreens, must be given plenty of room to develop, then they will furnish the front, and continue to do so afterwards for an indefinite period. It is surprising under favourable conditions what enormous bushes, beautiful in shape, Rhododendron ponticum will form in a very few years if given plenty of room; but these are generally planted thickly and allowed to become crowded and bare at the base.

Another advantage of planting thinly and thinning out the plants not wanted directly they show signs of crowding is the fact that those exposed to light and air will be thick all round, and thus brave winds and severe weather much better than when drawn up weakly together. In exposed situations it is of the utmost importance that each plant or tree stands separately with plenty of room to develop naturally.

Before planting it is necessary to trench the ground as deeply as the soil will allow of this being done. If the soil is poor and unfertile a good coating of manure should be added. For Rhododendrons and such evergreens nothing can be better to incorporate with the soil than leaf mould, for the majority of trees and shrubs grow most luxuriantly in it. When planting Hollies, Pines, or choice Conifers it is a good plan to give to each plant a few barrowfuls of fibry loam, to which about one-third of decayed manure has been added. This will give the plants a good start, and insure their lifting with good balls of roots when the first thinning requires to be done. If the soil upon the portion of ground to be planted is poor and shallow a greater quantity of fresh soil may be given to each of the choicer plants. When they are planted singly on the lawn or elsewhere a good-sized hole should be made, say three times the distance from the centre, that the roots will extend from the tree or shrub to be planted when first placed into the ground. The soil at the base should be well dug and manured, mixing with it a good percentage of fresh soil, which should also be incorporated with soil for filling in about the roots. If a good preparation is made at the commencement, and the surrounding soil is moderately deep and fertile, the tree or shrub will in all probability develop into a good specimen without further attention at its roots. When the soil is shallow it is a good plan after the roots have taken full possession of the soil prepared for them to cut a trench round them and fill it with fresh soil and manure. It is surprising how this helps plants, and in the end they abundantly repay for the labour expended upon them.

In order to insure quick luxuriant growth the ground should be well prepared by being trenched and manured as early in the season as possible. The planting, if possible, should be done before the ground has had time to become saturated with rain. Trees and shrubs grow much more luxuriantly in trenched than in untrenched land. This is the case, however, in the majority of soils. There may be exceptions to this rule.—WM. BARDNEY.

WHITE PLUME CELERY.

As this novelty is now receiving flattering testimonials from men whose opinions we have every reason to respect, I would like to ask

"Kitchen Gardener" or anyone who can speak from practical experience, how it turns out after a snowstorm?

"Kitchen Gardener" says, "Planting and weeding is the whole of the details necessary for its successful culture." If this he so, then it must indeed be an acquisition, and in these hard times well worthy of extensive cultivation; but will it, like Cabbages or Broccoli, rise after being beaten down with snow, and prove to be as good for a second-course vegetable as Celery grown in the old-fashioned way.

An answer to this question will, I venture to say, interest more than—J. MCINDOE.

"THINKER'S" NOTES.

SHOWING LATE GRAPES.—I have only to say that I feel I am no match for "Thinker" at "hedging" and evading a plain issue, and therefore decline to prolong the discussion. His last apologetic six paragraphs are a sufficient commentary on his earlier remarks. If it had been a simple question of whether some object was black or white "Thinker" would, I doubt not, have displayed just the same casuistry, and left the question where he has left the present one. As to the "sincerity" of my own convictions, it is at least as genuine as his own, which has not been called in question. It is his opinions that are criticised. I have done nothing at variance with the position I have taken up here, and "Thinker's" innuendoes and insinuations assume more than anyone has any right to do.—NON-BELIEVER.

P.S.—I have not used any such expression as "I do not show now because from a pecuniary point of view I can do better." The "now" is introduced by "Thinker" himself for a purpose of his own, and does not express either my position or opinion. The alteration is on a par with "Thinker's" other unscrupulous misrepresentations—to wit, his conversion of my "putting it on a low ground" into "accusing a body of men of being engaged in a low calling," in order to render his own dubious position less conspicuous.—N. B.

POTATOES.—In reply to your correspondent, I am able to say that in my opinion the Reading Russet Potato is a variety of considerable value for table use. It is a second early, ready in August, and of medium growth, producing well in rows 2 feet asunder. The tubers are of good and uniform size, rough in the skin, and, though this is dark, the Potatoes are quite white when cooked and of first-rate quality. I find a certain prejudice against coloured Potatoes in the market and amongst cooks generally, but the one I have to deal with is quite content with the variety in question. I know very little about the other red and Vicar of Laleham, but am told it is not very good.—A COUNTRY GARDENER.

NOTES UPON DAFFODILS AND NARCISSI.

(Continued from page 428.)

GROUP 2.—THE PEERLESS OR MOCK NARCISSI.

N. BARRI.—This is a sub-section, including several most beautiful varieties supposed to have originated from a cross between N. poeticus and N. pseudo-Narcissus. The following are what I have proved to be best and honestly worthy a place in any collection—Conspicuous, division rich yellow, very broad and large; cup yellow, conspicuously margined with scarlet; a gem of the first water. John Stevenson, divisions pale sulphur, cup of the same colour; very large and spreading. Maurice Vilmorin, divisions creamy white, cup rich lemon heavily stained orange-scarlet. Flora Wilson, yellow divisions, cup of same colour, distinctly edged scarlet.

N. INCOMPARABILIS (the Peerless Daffodil of John Parkinson).—The typical form is well worth growing, with its large flattish spreading flowers of a rich yellow, and very suitable for planting in masses. There are a considerable number of forms centring around this, arranged in the sub-sections of albus, albidus, concolor, and sulphureus, which space will not admit of enumerating even, and for further information concerning which I must refer my readers to "Ye Booke of Ye Daffodyl," published by Barr & Son, King Street, Covent Garden. I will merely select a few of the best varieties, and cannot do better than begin with Sir Watkin, a so-called new variety, certainly new to commerce, but it has been revelling in certain Welsh valleys I could name, perhaps for a century, nevertheless it is a first class kind, producing immense flowers, sometimes as much as 5½ inches across; the perianth rich sulphury yellow, cup unusually large, approaching the Ajax section, rich aureolin yellow, deeply fringed; it possesses a vigorous constitution, and will always be highly esteemed both of borders and pot culture. Mary Anderson is a gem, perianth creamy white, large and flat, cup deep orange scarlet; most conspicuous, indeed there is not a more effective variety. Princess Mary of Cambridge, large flowers with white perianth; cup large, very widely expanded, rich orange; a most distinct and beautiful variety. Stella, one of the oldest and best for cutting, as it comes in very early, following hard on N. poeticus ornatus; perianth pure white, cup pale lemon. Crawfordii, immense flowers, the perianth

divisions pointed and bent inward; cup rich yellow; a very handsome and distinct kind.

N. LEEDSI.—This represents a beautiful series of hybrid forms appertaining to *N. incomparabilis* in flower form, but supposed to have first resulted from a cross between *N. montanus* and *N. Pseudo-Narcissus*. Amongst the best are the following—*Amabilis*, perianth divisions silvery white, very large; cup very long and prominent, delicate primrose changing to white; extremely beautiful. *Gem*, divisions white, very symmetrical; cup very pale primrose, deepening in colour with age; this is one of the perfectly formed flowers of the series. *Superbus*, divisions white, large and drooping; cup long, primrose, fading to white with age. *Queen of England*, a model flower, with white divisions; cup canary changing to white.

N. NELSONI is a very distinct form with large spreading flowers; perianth pure white; cup rich yellow, rather long and cylindrical. *Aurantiaea* produces rather smaller flowers, and the cup is heavily stained with orange-scarlet, a gem of gems, but extremely scarce. *Pulchellus*, flowers of exquisite form, divisions white, cup yellow, smaller than the others, and drooping.

GROUP 3.—THE POET'S AND POLYANTHUS NARCISSI.

N. BURBIDGEI.—This represents a good number of very pretty early-flowering varieties, hybrids between *N. incomparabilis* and *N. poeticus*, but as they favour the latter most they are arranged in this group. The best of them are the type with creamy white divisions, and the cup edged with scarlet—*Conspicuous*, perianth divisions pale sulphur; cup large, edged with scarlet; a fine variety. *John Bain*, divisions white; cup citron; very lovely. *Jenny Deans*, divisions creamy white; cup yellow, edged with scarlet. *Robin Hood*, divisions clear white; cup lemon, edged with orange-scarlet; very distinct and effective.

N. POETICUS (the Poet's Narciss).—It is difficult to say which is the typical *Poeticus* Linnaeus examined when he christened this charming species, as the forms are very numerous, some early and others late-flowering, the first batch in March and April, the last following on in May, sometimes into June. Of the first series *angustifolius* is worth growing, the divisions are pure white, crown margined with rose; flowers rather small, and foliage narrow. *Ornatus* is in my opinion the best of all; pure white, with large, broad, flat divisions; cup margined with red most sweetly scented, and simply invaluable for cutting, &c. Of the May-flowering ones *recurvus* may be mentioned, which is commonly called the Pheasant's Eye Narcissus, and too well known to require description; to this belong the beautiful double-flowered form appearing at the same time, and universally in demand for floral work.

N. TAZETTA (the Polyanthus Narcissus).—There are a large number of charming varieties of these, but I will only name half a dozen. *Bazelman major*, immense trusses of large flowers, pure white, with yellow cups. *Gloriosus*, creamy white, with orange cup, very charming. *Grand Monarque*, large flowers, pure white, citron cup, a very striking kind. *Grand Soleil d'Or*, yellow divisions, rich orange cup, very free and bright, one of the best for general cultivation. *Jaune Supreme*, primrose divisions, and orange cup; very fine. *Paper White*, pure white, flowers much smaller than the others, but very early and useful for forcing. The value of these Narcissi for pot culture is well known, but they are not half so much appreciated as they should be; no greenhouse should be without a fair quota of them to cheer the early months of the year.

DOUBLE DAFFODILS AND NARCISSI.

N. CAPAX (Queen Anne's Double Daffodil).—A very pretty kind of perfect form, soft primrose colour, segments imbricated in the form of a star; it is comparatively scarce, but somehow it has accumulated in Ireland. I came across some fine batches there last spring which quite surprised me. It should certainly be in all collections.

N. CERNUUS, FL.-PL.—A duplex form of one of the Silver Trumpet, most beautiful and scarce, creamy white and primrose. There are two forms, one in which the trumpet is entire, with the tube well filled with segments; the other has the trumpet quite broken up, the divisions being more numerous and developed, when fully open resembling a Rose somewhat. This is, I think, the rarer variety of the two.

N. PSEUDO-NARCISSUS, FL.-PL.—This is comparatively scarce. In a wild state the trumpet is intact and filled with segments, but there is a charming variety which has been circulated recently as *albus aureus fl.-pl.*, which is in form much like *N. capax*, but the deep golden yellow and pale sulphur segments are prettily alternated, thus forming a most effective feature.

N. TELAMONIUS, FL.-PL. (Van Sion).—This is the old com-

mon double Daffodil of our gardens, and needs no further mention. All the foregoing belong to No. 1 group. The following belong to the Peerless section.

N. INCOMPARABILIS, FL.-PL. (Butter and Eggs).—This is a very common form, most abundant in many places, admirably adapted for naturalising, unfortunately frequently distributed for Orange Phoenix, a much superior kind. Those seeing the latter offered very cheap—well, lower than 12s. per 100, should fight shy of such an offer.

N. I. AURANTIUS, FL.-PL. (Orange Phoenix, Eggs and Bacon).—A grand variety with immense double flowers; the outside white, the centre sulphur and deep orange, most effective for borders.

N. I. SULPHUREUS, FL.-PL. (Sulphur or Silver Phoenix, Codlins and Cream).—Truly the Cream, if not the Codlins, of this series, producing very large flowers, at first pale sulphur, changing to creamy white, sweetly scented, and of elegant outline.

N. ODORUS MINOR, FL.-PL. (Queen Anne's Double Jonquil).—A very pretty dwarf-growing variety, with very double flowers of a rich golden yellow, sweetly scented, and most desirable in any border, where it should remain undisturbed, as it rebels against intrusion when once established. The double form of *poeticus* I have previously referred to. In concluding these notes I wish to impress upon the reader how inadequately they represent the great and lovely family of Daffodils, as the selection is a most rigid one, but as much more space is taken up than I had intended, for the nonce this must be sufficient.—J. T. R.

FRUIT AND PLANT HOUSES.

(Continued from page 421.)

In passing to the construction of houses I may briefly allude to the site, which for any purpose should be high and dry—i.e., if there is choice of site let it be such that the water will drain from the proposed structure. This more particularly applies to fruit houses, which are best when they are not only on rising ground, but have the masonry disposed that the borders will be so high the water will pass away freely. Even plant houses, except for special purposes, are best kept well above the surrounding ground level, particularly when the plants are of flowering size. Still, houses for plants are very often sunk, as they then afford a greater uniformity of moisture. Such are low span-roofs with often a sunken path as seen in nurseries for the growth of young stock, but these houses are not so common in private gardens as their usefulness warrants, especially as they are so inexpensive and appropriate for growing plants to furnish conservatories. One of the greatest mistakes made in horticultural building is having a large greenhouse or conservatory in which a display is expected to be kept without any regard to the means by which it is to be maintained. The large house is very well, but it proves disappointing unless aids are forthcoming in the shape of small houses in which plants can be raised to maintain the successional display.

In the matter of masonry or other base for the structure of whatever description little need be said, only it should be of sound durable material and put together in a workmanlike manner. There is one point, however, which I think deserving of more than passing notice—viz., the width of the masonry. For ordinary houses we have 9-inch walls with correspondingly wide wall plates, or 11 inches, leaving an inch inside for plates, and a corresponding inch or more outside to allow for drip, and its groove on the outside to cause the water to fall clear of the wall. Now, I do not believe in this waste of timber; in fact, the less we have of it the better alike for economy and durability. The larger the timber the greater is the danger or difficulty of securing or selecting it free from sap, knots, and other imperfections. There is no reason why the walls for three or four courses or a foot to 15 inches under the wall plate should be more than 4½ inches thick, especially if built in cement, whereby we add 4½ inches to the width of the house for each wall, and reduce the timber forming the front and back, side or sides, of the house by one-half without any depreciation of the strength or durability of the structure. This forms a ledge available for the hot-water pipes, or it may be used as a shelf for small plants, or if a stage it widens it by 4½ inches, which certainly is a consideration. In the case of low walls there is no need to have them more than 4½ inches thick if they have proper foundation and are built in cement.

It may be observed that I am fully cognisant of the value of thick walls in preventing the radiation of heat, as well as of their absorbent power both in regard to heat and moisture, and of their value in this respect there is no question. I see more reason, however, why even these, in the case of lean-to's or unequal spans, should be taken up their full thickness to the wall plates, but be narrowed to 4½ inches for their top three courses at least, so as to render less timber necessary, or lessen the necessity for an expensive coping by covering back walls with the glass, which would widen the house, taking back

and front together, by 14 inches, and that means a bunch of Grapes more per rod if not two, or a Peach per foot of surface gained. Of course hollow walls are better than solid, being warmer and drier and non-conducting, and which we may still have along with the narrowing of the walls where they receive the wall plates, as for the spaces to be of value they must be closed, which the narrowing of the walls causes to be done perfectly.

In timber, there is no objection against red deal, but it must be selected and thoroughly seasoned. If it contains sap it will not stand wet and soon decays. Any saving in first cost by the employment of unselected or unseasoned timber is very unsatisfactory and expensive in after repairs. A house built of deal containing sap I have known to become so decayed in seven years as to be unsafe, and I have found it so bad in a dozen as to necessitate their renewal. Sound, thoroughly seasoned red deal will last a lifetime if duly painted; indeed, half a century or more if properly put together, which has more than some imagine to do with the durability of glass houses. It is little use being careful about material if the joints are so bad that they will allow wet to enter, as decay is then certain to result, and what is the good of a roof with rafters or sashbars rotten at the eaves?

Pitch pine is better no doubt than red deal for certain purposes—i.e., in houses much subjected to moisture, but is more expensive and more costly worked; but the best of all is undoubtedly teak, which, however, is still more costly. These three—1, red deal, 2, pitch pine, and 3, teak, are, according to my knowledge and experience, the only suitable woods for fruit and plant houses. I have, it is true, seen some mahogany lights that were little, if indeed any, worse for wear after many years' use in a conservatory, and where they still are in excellent preservation.

Whatever wood is used, as little of it as is necessary to insure stability only should be used, so as to obstruct as little light as possible, and it should be strengthened or stayed in such manner by iron, whether in the shape of pillars, tie bars, or brackets, as to still further insure its stability against the violence of storms, as well as to prevent any departure of the timber at the joints. The joints of the wood, whatever they may be, should be perfect; by perfect I mean close-fitting, so that when the jointure is made, the parts to be joined being white-lead no joint will show, only pieces of wood joined together without so much as a crevice remaining, but contrariwise forcing out the white lead, and there is consequently no joint to putty up before or at painting. There is no opening for the wet to get in, and such is as good at the joints as in the solid. This is a main point in fruit and plant house construction, for good materials are only wasted by bad workmanship. I have had a practical illustration of this. I had a Rose house 54 feet by 15 feet put up by a horticultural builder (Messrs. Foster and Pearson, Beeston, Notts), into the joints of which a pin could not be pushed, and I did not see the painters going over the house before painting with the indispensable lump of putty in one hand and the putty-knife in the other. I do not think putty to fill up cracks—i.e., joints, were used to the extent of the size of a walnut either inside or outside the house. I have had other work done by local men, and I can push my knife (a Peach pruner) blade through plenty of the joints where the rafters join the wall plates. If the work is wanted to stand it must be good, otherwise it will be anything but economical. There is no cheapness in indifferent material imperfectly manufactured, true economy consisting in sound material employed in a skilful and thrifty manner.—G. ABBEY.

(To be continued.)

LONDON'S LESSER OPEN SPACES—THEIR TREES AND PLANTS.—No. 5.

A SHORT time ago all the world wondered—at least in west London—why some individual chose all of a sudden to dislodge, or attempt to dislodge, the seemingly inoffensive sellers of milk and cakes near the Spring Gardens gate of St. James's Park. People laid it to the charge of George, ranger, but he was exonerated, and Her Majesty forbade the removal of the last two persons, who still hold stalls there as representatives of "Milk Fair," well-known in Georgian times; but actually the spot, as a place for refreshments, carries its history back to a date before the great civil war, when in the reign of James I. there was a bowling green here, a pleasant walk, and gardens in which nobles and citizens strolled, or they ate and drank under the shade of its trees, the spring, from which the place takes its name, being one of its attractions. Evelyn, always an observer of trees, alludes to the thickets that once existed here, so suitable, he remarks, for the evening wanderings of lovers. But not long after the Spring Gardens underwent a change, the fowls were removed, the ponds filled up, the green walks closed, and part of the ground being absorbed in the Park, upon the remainder a frontage of houses was built. I wonder, by the way, since the fashion now is to revive antique pastimes, whether keeping pheasants for amusement merely will again become as popular as it was in the seventeenth century.

Gardens there still are at Spring Gardens, though not accessible to the public, between St. James's Park and the houses looking towards Charing Cross, and they have both trees and shrubs if the thickets are no longer to be seen. One part, indeed, of these gardens is so far overgrown that the paths are seldom dry, and some few flowers of a perennial sort that are scattered about put forth but feeble blooms. Perhaps, though no spring is visible now, there is a natural moisture here, for Poplars flourish, and Lilacs and other shrubs are generally more leafy in autumn than is usual about London. According to a local tradition, on the morning of his execution, as Charles I. took his way to Whitehall attended by his escort, he pointed to a tree in the Spring Gardens, and said to one of the officers, "That tree was planted by my brother Henry." I find there now no tree of sufficient age to date back from the period when this might have been planted. It is rare to find any tree growing near London much more than a century old, and then it would be either an Oak or a Yew; but curiously enough, there are sundry Yew bushes in Spring Gardens which may be descended from some Yew that has been removed.

Amongst the evergreens we noticed a few somewhat stunted Spruce Firs, a species seldom met with in old London gardens, and across one path there hung festoons of Clematis, leafy till November, though not displaying those feathery seed heads so familiar to the rural stroller, and which are exceptionally abundant along many lanes this autumn. As a rule we find the Elder, of all the deciduous shrubs growing in London, retains its leaves the longest, which may be one reason why it was formerly so much planted, though its appearance is not specially attractive. In this garden are some of those ancient Hollies that one comes across, whose utmost annual effort at growth is the putting forth an insignificant number of spring leaves, but then they persistently retain their old leaves year after year perhaps, until they slowly waste away on the branches. Many years ago, it would appear, round one side of the Spring Gardens a mound was raised as a screen, upon which various shrubs were planted. In course of time much of this earth has washed down, leaving the roots of some of the bushes partly exposed, but these are still growing and seemingly thriving. Outside the enclosure, and within the Park, yet certainly a portion of the original Spring Gardens, is a grassy space, of almost triangular shape, which has a large Plane in its centre, and a few others of different sizes along its side; here juveniles are occasionally permitted to gambol. This, it has occurred to me, may have been the site of the Spring Gardens bowling green, where princes once played.

Standing at the Spring Gardens gate of the Park we overlook Trafalgar Square, an open space which has received a large share of unkindly criticism, and one hesitates to add thereto, but really its trees are deplorable objects. Flowers the square has none, and its leafy display is limited to the foliage of the few Planes placed along three sides, the stems of which have a double casing of protective wood and iron. What leaves they have droop on branches high upon the lanky stems, and the removal of these trees would be no great loss. Doubtless the spot is ill adapted for horticulture, but might not something be done with the ponds? It would be no difficult matter to convert one of them into the semblance of a natural pond or lake by planting such species as the Flowering Rush (*Butomus umbellatus*), the great Reed Mace (*Typha latifolia*), the Arrowhead (*Sagittaria sagittifolia*), and others that could easily be selected as likely to flourish. Almost as bold in aspect as Trafalgar Square is the open space or esplanade to the west of the Horse Guards, which serves occasionally for military evolutions, undoubtedly the old tiltyard attached to Whitehall Palace, but this is relieved in a measure by the trees and shrubs of the adjacent enclosure. Not one in a hundred, perhaps, of those who cross this space skirt the side towards the Admiralty, where we come upon sundry plots of garden ground and Ivy-shaded walls, positively upon one line of wall covered with Vines. I do not suppose they would fruit here as once they did about Westminster, for the yet extant Vine Street was so named from a vineyard or Vine garden belonging to the Palace, and which is referred to in a warrant (temp. Charles II.) as if then under cultivation. Well sheltered from the north and east winds, shrubs and flowers of the common kinds flourish here. There were some large bushes of the ornamental Carrant, and fine Thujas, also we observed a species not usual in London gardens, the Bladder Senna (*Colutea arborescens*), and beside it the Laburnum also displaying its seed pods, seldom plentiful in a town atmosphere, which is quite as well, considering their very poisonous character. Another Cytisus, the bonnie Broom (*C. scoparius*) would have been an appropriate plant on ground of such historic fame as the precincts of Whitehall, and I believe this graceful plant might prove a desirable addition to many London gardens where it is now lacking.

Across Parliament Street, with the Thames once washing its edge, but now separated by the Embankment, was the Priory Garden—or private garden—of Whitehall, a space of between three or four acres. During the reign of Charles II., when gossiping Pepys was one of its visitors, the ground was laid out formally in sixteen square compartments, each having a central statue, and dispersed amongst the grass plots were some curious sundials. A high wall shut it off from the public gaze, and along one side was a row of tall trees that have long disappeared, Oaks or Elms perhaps. The houses of Whitehall Gardens and Richmond Terrace occupy part of the ground, part being still open and dotted over with flower beds, while on some portions of it are banks of evergreens. Of the trees interspersed, the principal are some notably large Poplars (*Populus nigra*) that must have made their growth under favourable conditions, also a few Planes and Limes.

Fronting New Palace Yard, and almost under the shadow of the venerable Abbey, is a small open space crossed by foot-paths, and within a low railing are sundry flower beds set in turf, and which during the summer are filled with a variety of flowers, Pelargoniums preponderating. The arrangement is geometrical, but much taste cannot be shown, as most of the beds are four-sided. The plan has been adopted of labelling the plants; not a bad one in a public garden, if the labels are so placed that they can be read.—J. R. S. C.

RENOVATING OLD STANDARD PEAR TREES.

OLD Pear trees may be transformed into young and fruitful trees by simply cutting the old fruiting branches to within 3 or 4 feet from the main stem. Some three or four years since I operated on some old trees of which the fruit had become distorted and undersized, they have now healthy young bearing wood full of fruit spurs. It is often a question with the owner of old trees whether to cut them down or from old associations to leave them standing. By this very simple treatment he can transform them into young trees. The old bearing wood appears to become too constricted and dense for the sap to flow freely. I have found that spur-pruned Vines, after seven or eight years, produce small bunches which gradually lessen. The same treatment applied to them furnishes young and vigorous canes.—T. FRANCIS RIVERS.

MR. SHIRLEY HIBBERD has in the press a volume of miscellanies addressed in the first instance to young people, but he assures us that people who are losing their teeth are allowed to read them, and they may hope thereby to renew their youth. The volume is to be entitled "The Golden Gate with Silver Steps."

— IN reference to the note of "F. J.," on page 403, we are informed by the Hon. and Rev. J. T. Boscawen that he has gathered seed of CHIMONANTHUS FRAGRANS ripened in a garden in Kent from which he has raised plants. "An Old Subscriber," writing from Hampshire, says he has a plant of *Chimonanthus fragrans* against a wall occupying a space of 100 square feet, which in warm summers invariably produces ripe fertile seeds.

— "SCIENTIA" says—"I believe it is the natural habit of that most beautiful of Lady Slippers, *CYPRIPIEDUM SPICERIANUM*, to produce annually two flowers on one stem. The plants I possess were only small, imported a few years ago, and the first time they flowered only one flower was produced on each stem, but every season since two flowers have expanded on each stem. It grows luxuriantly under stove treatment, and requires abundance of water. It is also important that the compost be open, using plenty of charcoal in lumps, renewing it annually. The pot or pan in which it is grown should also be abundantly drained, and the plant rested in a temperature of 50° to 55° for a few weeks, say while in bloom. It must not be kept dry at its roots during this period, but water should not be given it. The compost used here is living sphagnum moss and peat fibre in equal proportions, with plenty of charcoal and crocks intermixed."

— MR. C. ORCHARD, Coombe Warren, Kingston-on-Thames, sends us a handsome bloom of *CHRYSANTHEMUM M. HENRI JACOTOT*, and remarks, "It is naturally rather an early-flowering variety, and the very early buds produce blooms with shorter petals and less bright in colour than the later flowers, having much more yellowish bronze in the centre, which is not so effective as the later flowers. The buds should be taken about the 16th to the 20th of August if possible. It is a bad variety to produce cuttings, but it is a good grower and certain in producing flowering buds. It was shown very fine this year by Mr. Lowry at South Kensington and the Aquarium."

— MESSRS. LUCOMBE, PINCE & Co. have a good display of *CHRYSANTHEMUMS* AT THE EXETER NURSERY this season, this year's display eclipsing any previous one in the quality of blooms and improved varieties. About 500 specimens are on view, and these form a beautifully coloured floral bank, the front row being composed principally of dwarf Pompons, and the unbroken mass of flowers and foliage rising gradually to 7 and 8 feet in the back row. All the leading varieties are represented.

— "THE ORCHID ALBUM for November contains four handsome plates of very distinct Orchids, the general execution, together with type and paper, continuing of the same high quality as hitherto. The plates represent the following:—*PHALÆNOPSIS SANDERIANA*, a form with large beautifully formed flowers of the *P. amabilis* style, the two petals and the upper sepal of a soft blush or pale pink tint, the lower sepals and lip white, the latter dotted with crimson in the centre. It also resembles *P. amabilis* in growth, but is usually regarded as a natural cross between *P. Schilleriana* and *P. amabilis*. It was found by one of Messrs. Sander and Co.'s collectors on an island in the Eastern Archipelago, and was recently introduced by the firm named.

— "A VERY pretty and distinct Orchid with the habit of a *Bletia* is *GOVENIA DELICIOSA*," says Mr. B. S. Williams, and he further observes, "This genus belongs to the terrestrial section of Orchids, a group which is too generally neglected by cultivators." He also considers that the chief cause of failure in cultivating such plants is "over-watering" them when dormant. The one figured is a Mexican species producing a slight erect stem with two large ovate leaves and a long terminal raceme with the flowers clustered near the apex. The sepals and petals are white, the lip being curiously curved and covered with round purple dots.

— THE deciduous *Calanthes* include some of the most useful Orchids in cultivation, the vestita varieties being particularly beautiful. A grand variety is that figured in plate 211, *CALANTHE VESTITA OCULATA GIGANTEA*, which has remarkably large flowers, pure white, with a rich orange red blotch at the base of the lip. It possesses "a remarkably showy character, and, like *C. Sanderiana*, *C. Williamsi*, and *C. Turneri*, produces its blossoms after *C. vestita* and *C. Veitchi* are over. The foliage of the variety, moreover, remains green during the time of its flowering."

— A SPLENDIDLY coloured variety is *CATTLEYA GUTTATA WILLIAMSIANA*, which was obtained from Messrs. W. Thomson & Son's nursery at Clovenfords, the whole of the stock, except a plant at Downside, Leatherhead, being now in the possession of Mr. B. S. Williams. The lip is of an intensely rich crimson purple hue, the sepals and petals being of a purplish rosy tint, the petals much darker than the sepals, on which there are numerous spots of crimson. The flowers are borne in a strong head, terminating the growths.

— WE have received some PACKETS OF GISHURSTINE from the Belmont Works of Price's Patent Candle Company, reminding us of coming winter and the necessity for providing against wet feet. Ever since this useful preparation has been introduced we have used it, and found it of the greatest comfort in protecting boots from the effects of wet. But there is another use we applied some of it to, which the proprietors of it may not be aware of. We added about one-third of petroleum oil, and in this mixture we rubbed up some red lead, forming a paste of the consistency of cream. This we rubbed on wooden labels before writing on them with Wolff's pencil, and we have found the writing last as long as the label. It soaks into the wood and enables the pencil to make an indelible stain.

— "LANCASTRIAN" observes—"EPACRIS MULTIFLORA is not generally known or very plentiful, for very rarely is this variety met with in private gardens, neither is it generally cultivated by nurserymen. This is to be regretted, for it is doubtless the best late-flowering variety in cultivation. It is perhaps not so profuse a bloomer as many varieties, but if its strong upright growths are well ripened it will not fail to give satisfaction in this respect. Its flowers are bright crimson and white, which render it one of the most showy varieties when in bloom. It is a strong grower, with rather large leaves, and therefore totally distinct from all varieties known to me. Its great value is its late flowering, and those who require good flowering plants for cutting or for decoration in pots should procure this grand variety. It is necessary after flowering to push it forward, or it will not complete its growth sufficiently early to ripen the wood, and if this is not accomplished it will fail to flower satisfactorily. It is also necessary to cut its growths close back after flowering, for if a few inches are annually left it will not be long before it is bare at its base."

— HORTICULTURAL CLUB.—The monthly dinner and conversation took place on Tuesday, the 10th inst., at the Club room, 1, Henrietta Street, Covent Garden, when there was a goodly attendance of members, including the Hon. and Rev. J. T. Boscawen, Rev. F. H. Gall, Messrs. Wheatstone, Loder, Wood, Ingram, Collings, Balderson, &c. The

subject for discussion was Grape-growing, opened by the latter gentleman, who detailed his method of cultivating ten varieties of Grapes in one house, and showed its success by exhibiting good, well-finished bunches of Mrs. Pince, Madresfield Court, Muscat of Alexandria, Foster's Seedling, Duchess of Buccleuch, Golden Champion, Black Hamburgh, &c., which were (especially Mrs. Pince) pronounced to be excellent. The Secretary then gave some account of the Castle Coch vineyards of the Marquis of Bute, near Cardiff, and by the courtesy of Mr. Pettigrew, his lordship's able gardener, the members were enabled to taste the produce of the vineyard, a bottle of the vintage of 1881 having been sent by him for that purpose. It was pronounced excellent, and bore a likeness to a good still champagne. The discussion was continued by Mr. Boscawen and others, and the thanks of the members were given to Mr. Balderson for his interesting paper, and also to Mr. Pettigrew for his courtesy. It was announced that the discussion for the next meeting would be opened by Dr. Masters.

— WE learn that CAPTAIN E. S. BAX (late 84th Regiment) has been appointed Assistant Secretary to the Royal Horticultural Society, in place of Mr. Henry R. Newport.

— WHEN difficulty is experienced in keeping GRASS GREEN UNDER TREES IN OPEN WOODS, particularly Pine woods where shade is continuous the year round, the "Journal of Forestry" recommends sowing a little nitrate of soda occasionally throughout the growing season when the weather is moist. This will bring a fine crop of verdure pleasing to the eye and agreeable to cattle.

— AN American contemporary states that during the past season there were put up 48,508,248 cans of TOMATOES in the United States, being one-third less than the pack of 1883, the decrease in acreage being heaviest in the eastern States. It is said that a farmer in Salem County, New Jersey, last season raised 83 tons of Tomatoes on 6 acres of land. The crop was sold in the canning establishment for 7 dollars (nearly 30s.) per ton.

EARLY TULIPS.

THESE merit special attention, as they are easily forced into flower, and are more showy than any bulb which blooms in winter. Early Roman and other Hyacinths are valuable, particularly on account of their delicate colours and delightful fragrance, but for conspicuous show the Tulips have merits all their own, and wherever a bright display of flowers is desired during the dullest and most cheerless winter weather the early-blooming varieties should be grown. They are easily managed, and bloom with great certainty.

The single-flowered sorts are the best for early forcing. They grow and expand more freely than the double sorts, and in my opinion they are more graceful, especially when in the bud and not fully expanded. Our best early varieties are Canary Bird, clear rich yellow; Bride of Haarlem, white striped with crimson; Pottebakker in three colours, scarlet, white, and yellow; Le Matelas, white suffused with bright rose, very fine, but not the cheapest. All the Duo Van Thol varieties are excellent for early forcing. They are red, crimson, gold, scarlet, rose, white, and yellow in colour. The common scarlet, which is exceedingly showy, may be bought at 4s. per 100 bulbs, but the white is very much dearer. We are very fond of the scarlet, as it is so very showy for floral decorations at Christmas.

I prefer the single flowers for early work, but some may like the double ones best, and the best of these are the double Duc Van Thol, La Précoce; the two Tournesols, red and yellow; Imperator Rubrum, and Murillo, which is pale rose and white. When the sole aim of growing them is to cut them, the bulbs may be planted in batches in shallow pans or boxes, but where they are wanted for decoration in pots these should be used of various sizes. We sometimes pot the bulbs singly in 3-inch pots, others are placed in threes in 4-inch pots, and more in 5-inch and 6-inch pots, but no size larger than the last is used, and five or six bulbs in these make very pretty groups. The earliest may be potted in October, or as soon in November as is practicable. The soil used in potting should consist of three parts light loam, the other half-decayed manure and a dash of sand. A little drainage must be placed at the bottom of each of the pots. They may be filled to the rim loosely with soil, then insert the bulbs, and finally press the soil down firmly about them. When potting is finished the top of the bulbs should just be visible. When the soil is moderately moist no water need be applied, but they should be plunged at once under ashes, sawdust, cocoa-nut fibre refuse, or sand to the depth of 6 inches or more. Their position then may either be in a cool shed in a frame under a wall or out in the open. They must remain plunged until the growths are about 2 inches in height, and to attain this they must stay under the covering for three or four weeks, and when taken out they should be introduced to a temperature of 65° or more. There they will soon show the flower buds, and bulbs potted the first week in November will be in bloom by Christmas and the new year. The whole may be potted at once, plunged together and taken out on the same day, if the growths of the different varieties indicate that they are ready for

this. Successional flowers may be produced by placing a quantity of them in cool house or frame, and transferring a number now and again to the warmer quarters. The Duc Van Thols should be largely grown for Christmas decorations.—J. MUIR.

CANKER IN FRUIT TREES.

IN his note under this heading, Mr. Hiam says (page 404) that he has thought about it and written about it until he is tired. I, too, have thought about it for over four years, two years of which I spent in a situation where every Apple tree on the place was more or less cankered and almost barren, so that the fruit room was filled annually with bought fruit. Last year we were able to fill it with "home-grown," while this year we could sell some surplus. To be brief, my opinion, and it is a firm one, is this—Gardeners, as a rule, spoil their fruit trees by too much kindness in two ways: first, by digging and manuring annually; secondly, by a too frequent use of the knife, commonly called pruning, but which in many cases is simply cutting into some shape agreeable to the eye. This has more to do with canker than many will admit.

The remedies used here were not in any way elaborate. Lifting and root-pruning were adopted in most cases, in others all cankered wood was cut out carefully, the latter and syringing with petroleum mixture being purely out of respect to Mr. Hiam's insect theory. Might I be allowed to "blow my horn" I would say that if given healthy trees to start with (healthy trees should have stock and scion of an equal growth without rupture or blister) a moderately firm soil with good drainage, the roots being kept to the surface by mulching, and I venture to predict that canker would be a thing of the past.—C. L. RITCHIE, *Redhills House, Belurbet, Cavan, Ireland.*

CHRYSANTHEMUMS LA PURETÉ AND MDLLE. LACROIX.

WHILE perusing the interesting series of articles entitled "Amongst the Chrysanthemums" in the *Journal of Horticulture* for the 5th of November I was no doubt, in common with many other readers, struck with the curious coincidence concerning Mdle. Lacroix and La Pureté.

The former, or more accurately speaking a variety bearing that name, is in my collection, and a few weeks ago I was impressed very forcibly with the great resemblance that Mr. Owen's variety La Pureté bore to it.

This was at a recent floral committee meeting of the N.C.S., and the decision they arrived at that the two were identical did not surprise me when reported in a contemporary journal.

It now appears that there is abundant evidence that the Chrysanthemums bearing the two names are everywhere proving to be the same thing, although both names have been recorded on the certificates granted to the flower. This fortunately is not of so frequent occurrence as might be the case, and there is probably no one flower except that with which I am now dealing that has been certificated so many times under two different names.

Last year we had almost a parallel instance in the case of Jeanne d'Arc and Mdle. Madeleine Tezier, the former of which, however, had happily received a certificate aright, although it was also discovered under the latter name. But these two varieties were subsequently found to be distinct, and so I venture to believe will those which properly bear the names of La Pureté and Mdle. Lacroix.

As in cultivation in this country, there is, as previously said, but little doubt that one flower passes under two names, and the question to be decided is, What is the proper name to be applied to it?

These varieties, La Pureté and Mdle. Lacroix, were raised by a grower whose name is not familiar to any great extent in this country, and were distributed by him as far back as 1882, if not two years before. The descriptions given in his list of novelties suggest the idea of two different coloured flowers, and it can hardly be imagined that any man would send out in the same set one flower under two names and with different descriptions. I do not of course say such is an impossibility, but still, prudence would certainly not commend a proceeding of this kind.

As far as I know few English nurserymen deal direct with the grower referred to, and in this fact lies the whole of the mystery, according to my way of thinking. Had La Pureté and Mdle. Lacroix been obtained in the first instance from the fountain head the first would, there is every reason to assume, have proved to be the white variety we now have, and the other would have been a flower of a rosy hue.

My belief is merely founded upon catalogue information, and is naturally put forward with the hesitation that such meagre information supplies, but in substantiation of this one of my correspondents in France, a large and able grower, gives the two as distinct varieties. Some readers may be interested in having the original description, which I append hereto.

"LA PURETÉ.—Japonaise; fleur énorme à longs pétales diversés, tuyautés d'une blancheur incomparable unique dans les Japonaises (extra belle).

"MDLLE. LACROIX.—Japonaise; fleur de toute grandeur, d'un blanc rosé, passant au blanc pur (superbe)."—C. HARMAN PAYNE.

GRAPES—JOHN DOWNIE v. ALNWICK SEEDLING.

AS Mr. Dunn and Mr. Downie have apparently deemed it unnecessary to give any reply to my question upon the above Grapes, therefore it is with some reluctance that I again revert to the subject. In the first place I wish it to be clearly understood that I impute no unworthy motive to either gentleman, everyone who, like myself, have the pleasure of their

personal acquaintance will, I am sure, agree with me in saying their integrity is beyond all question. But the fact of Mr. Dunn giving a high testimonial to a Grape said to be new, leads Grape-growers like myself to believe that by possessing such a one we should be adding to our collection a sterling novelty—a valuable late-keeping variety. It has now been proved by the Fruit Committee of the Royal Horticultural Society, Mr. Temple, and myself that this sterling novelty and invaluable late-keeping sort is none other than our old friend Alnwick Seedling under a new name. To be fair Mr. Downie should answer your important question, "Where and by whom the Grape John Downie was raised" (page 310). I think some explanation is also due to those who have invested their guineas in Vines of the same. Mr. Temple has been good enough to say he discovered last year that Alnwick Seedling and John Downie are identical, and drew Mr. Downie's attention to the fact, who, in reply, stated that he believed a mistake had occurred in sending out this Vine, and that the real John Downie was more like Gros Colman than Alnwick Seedling.

It appears odd that such an industrious writer as Mr. Temple should allow a whole twelve months to pass without mentioning the discovery. I would now like to know what has become of the John Downie that was said to be like Gros Colman, and if my memory serves me right it was also said to have a strong Muscat flavour; the variety supplied to me is clearly devoid of those qualities. Will Mr. Downie enlighten his customers, or must they conclude the description has been an exaggeration? —J. MCINDOE.

STRAY NOTES.

THE style of grouping now becoming general in houses, and especially in greenhouses and conservatories, is a decided advance on the old mixture system, for instead of seeing half a dozen or more plants of a kind spread over a whole stage, individually not striking enough to attract attention, they are collected together in a group not only showing to the best advantage themselves, but the groups may be more readily blended one with another. Groups of bedding Pelargoniums showing plenty of flowers are just now extremely attractive, the charming contrast of the large deep scarlet trusses, backed and intermingled with stray flowers of Chrysanthemum is really very fine, and well worth carrying out on a large scale. Rhodichiton volubile is also very attractive just now, hanging in graceful festoons from the roof, suggesting its use also on a more comprehensive scale, not only in the conservatory, but as it flowers well during the summer months in the open on south exposures, it will be found very useful for temporary rustic work.

Few pillar plants, except the Cestruums, can vie for present beauty at least with Begonia fuchsioides trained up a pillar, and although it has flowered all the year, it is just now as attractive, and certainly far more welcome than it was months ago. Coronilla corymbosa var. glauca, though in all probability hardy against a wall in the open, makes a first-rate pot plant, supplying a deep golden yellow shade not quite given by any of the Chrysanthemums we have yet seen. It seems to flower freely in pots, and may be treated along with the Azaleas, &c., during summer. Salvia Bethellii, which differs little, if any, from the S. involucrata, gives a rich rosy purple, certainly not surpassed at present, the curious hairy hoods of the flowers rendering them quite conspicuous among such species as S. Heeri, S. caliaefolia, &c. A group of Bouvardias looks very well also. A good double white is Alfred Neuner, Vreelandi being amongst the best of the single whites, and perhaps the easiest to manage, while Dazzler, for a scarlet, can hardly be surpassed. A mixture of the commoner pink-tinted sorts, of which there are a good many, also looks well.

Salvia Pitcheri in groups is really fine, varying with two or three distinct tints, from pale to a very rich deep blue. It seems quite distinct from S. angustifolia in having larger flowers and broader leaves. Kennedy's Marryattæ, as a rafter plant for roofs, cannot be surpassed. It is just now literally covered with bunches of large Pea-like intensely scarlet flowers, and well clothed with trifoliate woolly leaves, with the margins beautifully crisped or undulated, giving it a very interesting appearance. —M.

CHRYSANTHEMUM "NOTES" AND CHRYSANTHEMUMS FOR DECORATION.

I AM sorry if not true Mr. Pithers should speak disparagingly of the judging at the Dublin Chrysanthemum Show of last year; and if true the matter is all the more to be regretted. I need not tell Mr. Pithers Dublin contains some as good judges, and I believe I may add as good growers as there are in the world, and the fact that through mistake or ignorance a cut bloom gets wrongly labelled is no reason whatever to twice repeat—last year and again this—the same strictures. Those who try to maintain Chrysanthemum or other flower shows in Dublin, or other towns in Ireland, to my mind—there being no comparison between the difficulties to be contended with in the two countries—should not be looked on with a censorious eye, but have their exertions handsomely acknowledged. A few local gentlemen here are getting up a Chrysanthemum Show this year for the 27th inst., and so far have met with the warmest encouragement, though the times are still in some respects "out of joint." Probably I shall be your reporter on the occasion, and I may as well tell you beforehand, I will not look too nicely—even if I were competent—whether some of my gardening friends made a mistake in labelling a cut bloom, or whether my friend Mr. Burhidge, F.L.S. (who has been invited to come down as judge), gave a point more or less. Personally, I only grow Chrysanthemums for decoration and for my own amusement; a large

portion of them, at least one thousand, being trained against a southern wall, and capable of being protected should severe frost set in. As yet not even Dahlias have been injured with me. If such weather could be guaranteed every year, such a position and equal facilities, of course no one would hither growing Chrysanthemums for cutting in pots. I have larger blooms of the Christine and Mrs. George Rundle family, Empress of India, Refulgence, Cassandra, Lady Slade, Fingal, Prince of Wales, Golden Queen of England (at least 6 inches across), Dr. Sharp, and Emperor of China and so on, not to mention Japanese, Pompons, or Hybrid Pompons, thus planted out than those I have in pots. Some experts have seen and admired their unexpected size and substance, but especially the colours. As a matter of fact, the colours never come out as well indoors. Then whenever a lady visitor calls, I can always supply a large bouquet of blooms, and these outdoor-grown blooms last at least a week longer in vases than pot-grown forced blooms indoors, besides being much brighter. This, of course, may not apply to the same extent, in large manufacturing towns so well as in the country; but as a matter of fact, every country gentleman's residence, every villa and suburban garden, especially those with vacant spare southern walls, should have them bright and gorgeous during this dark and gloomy month.—W. J. MURPHY, Clonmel.

MOWING MACHINES.

How often in many gardens do we find, after the mowing season is over, the machines put away and left until the spring before any attempt is made to clean them; yet, what time is more convenient than the autumn or early winter months for the operation? Should the grass be wet the last time the machine is used the blades and bottom cutting plate would immediately become rusted. This, if left for any length of time, will act seriously on the most important part of the implement, and be sure to affect its working and lasting capabilities. It is a good plan to rub a little oil or grease over these parts before the machine is put aside when last used, as this would prevent rust. We choose the first wet day convenient, and take to pieces and clean every part of the machine thoroughly. An old table-knife and a spoke brush we find most useful for the purpose. The roller adjustments are generally the most difficult parts to dissect, but a man used to the machine and who takes an interest in it would soon surmount the difficulty. Twice a year is not too often to go through the process of cleaning if time could be found, but this is an exception, I think, rather than the rule in most places. The early winter months are preferred to the spring, as at this time the routine work is not of such importance as at the latter time, and it sometimes happens when so left that it is never done at all.—S. B.

IN THE VALLEY OF THE WILBERFORCE.

(Continued from page 409.)

FRIDAY morning broke brightly, and we made sure of a good day's collection in Happy Valley and Rebel Creek, which flows into the Moa River a short distance above the camp. Senecio Lyalli with pure white flowers and dark green foliage was growing near the water. It was evident that this valley has been filled with ice in winter, a mass remaining unmelted, with water running through a tunnel beneath. This valley bears due south, and the ice had but recently melted; so that vegetation was springing up. At one place in a bed of broken rock and shingle there was a grand Alpine garden. Both the yellow and white Mountain Lilies by the thousand were in full bloom, interspersed with the white Marigold (Senecio Lyalli); Ligusticum prolixa, with its highly ornamental foliage, was dotted about among the Lilies, and even the little Montias were represented in this natural garden. The most graphic description would fail to give an adequate idea of the purity and beauty of these Alpine flowers when seen in their natural habitat in broken ground among rocks and boulders, piled up in every conceivable position as the glaciers and floods have left them. Only one variety of Aciphylla grew in this cold valley which the sun never enters. Everything was frozen; indeed it was dangerous work, as we could get very little grip with our feet on the shingle slips, which had become transformed into ice slides. On a cliff we saw a fine patch of Edelweiss, far out of reach, also large plants of Ranunculus Godleyanus just coming into bloom. Polystichum cystostegium, the Alpine Fern, adds much to the beauty of the scenery, its green fronds contrasting with the rocks. On a bank of shingle and rocks were small patches of the pretty annual Euphrasia antarctica; Raoulia were represented by several varieties, australis and subcericea being the most prevalent. Mosses and Lichens grew on every rock, but few were in fruit. Of Acenas there were several species, adscendens and microphylla occurred very often in the Moa river bed. Coriaria thymifolia, the little Tutu, was plentiful, looking very much like the garden Thyme. Veronica linifolia with its delicate pink flowers grew in the river bed, also V. Bidwillii, which was in seed.

Arrived in camp at six o'clock, and shortly afterwards a nor'-wester set in, the wind blowing down the gully with great force. The hot wind of the plains is very different in the ranges; the rain came down in torrents, and by six o'clock next morning we could hear the boulders crashing down the creek. Looking out of the door of the whare on Saturday morning we saw what one night's rain from the nor'-west can do. The North Creek was full from bank to bank, the waves rolling up 2 or 3 feet high. It rained heavily nearly all Saturday, but cleared up on Sunday afternoon, and the rivers fell almost as quickly as they had risen.

In the bush we saw nine distinct species of Ferns. The Filmy Ferns were represented by *Hymenophyllum Malingi*, one of the rarest of the family, which grew on dead Cedars with a north aspect, *H. multifidum* carpeted the ground with its bright green fronds, *H. polyanthos* grew on the trees, but was rather scarce, *H. villosum* was found on bare rocks in very exposed situations, *H. scabrum*, with its long drooping fronds, in damp places. *Asplenium Colensoi* (the Grove Fern) was prevalent, growing very large in the bush. *Polystichum vestitum* was very common; a forked variety of it was found by Mr. Brown. The Carrot Fern, *Asplenium Richardi*, and *A. flabellifolium*, were scarce. *Cystopteris novae-zealandiae*, which is one of the few deciduous Ferns, was very plentiful, its pale green fronds making it easily distinguished. Of *Lomarias* we saw *lanceolata*, *alpina*, and *discolor*. The little *Polypodium australe* grew on dead trees. *Goniopteris pennigerum* was very scarce. Of *Lycopodiums* *Billardieri* was growing in hollows of the Pitch Pine, and *L. Selago* covered patches on the ground 2 or 3 yards across, looking like a bed of seedling Conifers.

Mr. Brown, who devoted himself to the collection of Mosses, found several new species of *Andreaeae*, *Weissia*, *Tortula*, *Orthotrichum*, *Eremodon*, and a *Polytrichum* with flat ovate capsules. *Dicranum clathratum*, a rather scarce variety, was abundant in this district. Of *Hepaticas* there were *Gottschia ciliata*, *Madotheca Stangeria*, and *Tricholea tomentosa*.

Monday morning was fine, the sun shining on the distant peaks, so we said good-bye to our friends who had treated us so kindly at the camp. Mr. Lander gave us valuable information as to the habitats of the plants, and Mr. Slater and Mr. McClure, of the survey staff, were equally ready to be of service to the first party of botanists who had visited these remote ranges. The cook lent us his horse to carry our swags to the lower camp, and we were put across the main branch of the Wilberforce by one of Mr. Lander's men. It was 4 P.M. when we got over the river, but we managed to reach Fisher's whare, and remained there all night. Made a start at daybreak, and had some difficulty in crossing the Harper, as the ford had been washed away by the heavy flood; we had to go a long way up stream before we found a safe crossing place. Having crossed at a fork, we made good progress to Lake Selfe, where, during a short halt, we found a terrestrial Orchid, which with the Water Quillwort, we added to our collection. Reached the head of Lake Coleridge at dusk. One of the miners who had a horse came up with us near Lake Lyndon and carried our heavy swags to the hotel at the foot of Porter's Pass, where we arrived at 7 P.M. Next day we were fortunate in getting a lift in a dray going to Springfield, and were glad when we found ourselves in the train for Christchurch, where we arrived at 7.40 thoroughly knocked up, but satisfied with the result of our ten-days trip to the district of the quartz reefs of Canterbury.

SNOWDROPS.

THESE would appear to be unusually early this year, as quantities were to be seen the last week in October peeping through the soil. Large quantities are planted round the borders of the shrubbery here; where overhanging branches shelter them they are much in advance of the others less favoured. No doubt the long spell of dry weather this summer ripened the bulbs early, and this, coupled with a mild autumn and frequent rains, would favour an early growth; consequently, early flowering may be expected should the winter not be too severe. They are highly esteemed here when in bloom for house decoration in pots, and for this purpose clumps are taken up from the borders and reduced when necessary to a size sufficient to fill a 6-inch pot. When the buds are formed is the time we commence taking up plants for pots; these are placed in a warm greenhouse and kept well watered; some fresh green moss is put around them to serve the double purpose of giving a neat appearance and to keep the soil regularly moist. As soon as the flowers begin fading they are planted in the borders from whence they were taken and allowed to ripen naturally, others being lifted to fill their places. By these means only sufficient are potted for the use of the house, as limited glass space necessitates as little overcrowding as possible.—S. B.

HYDRANGEAS IN THE OPEN AIR.

I HAVE a very high opinion of these, which is no doubt produced by the specimens we have here. They are all over the pleasure grounds. Many are round bushy plants 6 feet high and 10 feet through. Sometimes I have counted 700 heads of bloom on one plant, and from 300 to 500 is about the average. In the lower part of the grounds the flowers are a bright pink colour, but farther up they are of a bright blue. Some prefer the first, others the latter. They come into flower about the beginning of August, and remain fresh and effective until frost cuts them off, which is never before December. They are very striking the whole of the time they are in flower, and they make as good a display in autumn as the *Rhododendrons* do in spring. The heads of bloom are hardly so large this season as I have seen them. I think the excessive drought we had in July and August hindered their development. In some seasons, when the blooms were at their largest, the whole plant has been such a mass of colour that it was almost impossible to catch a glimpse of the green foliage anywhere, and I think they are prettier with the heads of bloom smaller and the foliage showing through between them than they were when one mass of colour.

They are very handsome, and might be planted out more often than we see them. Many consider they are tender and would not bear the

winter in all parts, but this is a mistake. I do not mean to say that they will withstand any amount of frost, but they will bear a low temperature, as those here have been exposed to a temperature 18° below freezing point for a considerable period, and they were neither killed nor checked. We generally allow the flower heads to remain on all winter, and these afford the stems much protection. I feel sure if those of your readers who have plants in pots would not coddle them during the winter, but keep them outside and harden them well, they might safely be planted out in almost any part of the country in spring. They would not grow very luxuriantly in bleak exposed positions, but in front gardens in town or country and sheltered parts of pleasure grounds and woodlands they would soon become the wonder of all who saw them. A rich soil suits them best at all times, and as the plants become large and have drawn a large amount of nourishment from the soil, liberal top-dressings should be put round them every autumn. In Scotland and the north of England I have often seen these plants matted for the winter, but we never practise anything of the kind here, and probably much harm is done by giving protection before it is wanted or in cases where it could be dispensed with altogether.—J. MUIR, *Margam, S. Wales.*

PLANT-GROUPING FOR EFFECT.

IN the paper read before the Dundee Horticultural Society by Mr. Williamson, appearing in the *Journal* September 17th (page 256), on "Tables of Plants," is very interesting and very ably treated. I may say the few remarks I now venture to make were penned the following week, but withheld in the hope that someone more able than myself might ventilate the subject.

Nothing, perhaps, has done more to enlighten gardeners than the styles of arrangements in grouping, and doubtless Mr. Wills is entitled to some gratitude, not only from gardeners, but the furnishing and plant trade generally. Mr. Williamson dwells at some length upon the wording of schedules, and certainly much pains is needed in order to convey a correct idea of what is to be the judging line; but, as careful as committees may be on this point, there is certain to be a great diversity of style and tastes displayed, because of the different plants at disposal, and a style of arrangement must be adopted to suit the plants. Therefore, in order to exhibit really high-class groups to harmonise in all points, considerable forethought is required. As in bedding out, the real object must be pre-arranged; each plant must be as near as possible the required size; and, again, each plant must be a specimen in itself. When this is done not many unsightly and almost useless plants will be retained. Such high-class groups certainly appear to be the most interesting feature of good shows, and when such interest is carried home the benefit must be general, and when groups are arranged at home prior to any particular show or shows young men derive considerable benefit and become more interested in the well-being of the plants. There is one very apparent benefit, that requiring a great number of Ferns in various sizes. These are also useful for cutting purposes, as thickly grown plants are not so light or effective, and a few fronds are no loss; and, again, when Ferns are thinly placed as a complete groundwork upon the stages, in a conservatory or greenhouse, what a pleasing effect is produced by having other well-grown specimens, large or small, also thinly dispersed, springing up in various heights.

Plants must be specially prepared; and, further, certain plants are almost indispensable for the purpose, having a goodly supply of Maiden-hair Ferns, *A. gracillimum*, *cuneatum*, and others in smaller quantities; also *Panicum variegatum*, *Selaginella caesia*, *arborescens*, *Kraussiana aurea*, and several equally graceful, and especially *Lygodium scandens*.

The next important point is a centre plant, and here is a point worthy of some discussion. Many use *Cocos Weddelliana*, but, rightly or wrongly, I have never admired this as a centre, often because many of the same have also been used in other parts of the group. *Dracaena Veitchii* is also, if employed, and if a well-grown plant, has fine effect. The best Palm for most forms of groups, in my opinion, is *Phoenix rupicola*. Centres must of course vary a little to suit the surrounding plants.

Crotons may be regarded as of next importance, as without a fair selection of well-grown *Crotons* a group can only be of average quality. This means that a gardener who has not a stove has no chance, and the only way would seem to be to offer prizes for groups of plants arranged for effect without stove plants, meaning, of course, such plants only that require stove all the year round. *Crotons* are so numerous in point of variety and colour, and I may also add reasonable in price, there is nothing to prevent anyone having a good collection, the drooping and narrow-leaved varieties being generally most effective, though some of the stronger growers, when well grown and coloured, are very useful. *C. volutus* at its best, on single stem, is one that is much admired; and, with regard to single stems, these are by far the best in nearly all varieties for grouping purposes. Nothing can excel in appearance a *Croton* 3 feet high, and yet retaining all its foliage; and to do this requires no small amount of skill. Regarding compost, has anyone tried an equal mixture charcoal, half-inch bones, and oyster shells crushed? We have, and shall continue it.

Of *Dracaenas*, old terminalis and *Cooperii* are among the best, on account of their free growth and rich colour, though many of the newer varieties are extremely effective when at their best. *Amabilis*, especially towards the back of some groups, is very telling. Another variegated and indispensable plant is *Eulalia japonica*, which is easily managed in all sizes. With a fair number of these it is almost impossible to have a group too stiff or too green. Then may follow Palms of various heights, such as *Cocos*, *Geonoma*, *Calamus asperimus*, and other choice forms.

To look well they should always be raised above the other plants, especially towards the centre or back. *Grevillea robusta* is another most useful plant. *Aralia Veitchii* and other choice varieties are most effective in any size and in any part of the group. Small plants towards the front make a good relief to Palms. *Acalypha musaica* from 1 to 3 feet high, on single stems, grown with Crotons, are very useful; but these must by no means become dry, or the leaves blister and fall. *Acacia affinis* and others of similar growth may be found a place, especially in large groups. *Pandanus Veitchii*, well coloured, in, say, 4 to 6-inch pots, give a great relief. Numerous other foliage plants may be used with advantage, yet those I have mentioned are hardly to be dispensed with in good competition. I have not mentioned *Caladiums* or *Coleuses*, each of which are telling, and *C. argyrites* in quantity renders a fine finish in the front line.—LATHYRUS.

(To be continued.)

JUDGES AND THEIR WORK.

I HAVE read with regret the letter of your correspondent, "J. L. B." in your issue of the 22nd October last upon the above subject, which it is quite patent refers to this town. I have been connected for many years with floral societies in Leicester. The remarks of "J. L. B." are absolutely untrue, and even if correct are a direct insult to the gentlemen referred to. "J. L. B." says, "There are but few examples worth going to see, as many of the best exhibitors do not show now." My experience is that the exhibitors of both vegetables and flowers at the shows in Leicester are equal and in many cases superior to other shows, and that the best exhibitors have not decreased, which has been proved only this week by both the quantity and excellence of the exhibits and the large attendance of the public at our annual Chrysanthemum Show.

The gentlemen referred to in "J. L. B.'s" letter are acknowledged to be thoroughly practical and experienced gardeners, as proved by the positions they hold, and also the excellent condition in which both the cemetery, public park, and the clergyman's rosery are kept and also admired by thousands. The superintendent of the cemetery has not acted as judge for two years. From the tone of "J. L. B.'s" letter he has evidently been a disappointed exhibitor; but if so, and he resorts to such a meanness as to endeavour to ridicule the decisions of the gentlemen mentioned, why the sooner he ceases to become an exhibitor the better, as such men are not worthy to be connected with flower shows.—L. V. HEATHCOTE, *Secretary of the Leicester Chrysanthemum Society*.

[Our correspondent did not name Leicester, but simply mentioned "a Midland town."]

VENUS'S EARLY DWARF CABBAGE.

I AM always glad to recognise any new or old varieties of vegetables when they come to the front if they are of sterling merit, but when any old variety is about to be distributed under a new name I think it is time to speak out. As we make vegetable-growing a specialty here, and early Cabbages one of our fancies, having grown most varieties I am not without considerable experience on the matter.

I see an article in your issue of November 12th from Mr. Oliver, Eslington Park, in reference to a Cabbage that is in the possession of Mr. Venus, Allerburn House, Alnwick, and I also observe it is to be offered to the public shortly as a new variety under the above name in the advertising columns of the *Journal of Horticulture*. Now before it is sent out I would advise Mr. Oliver and Mr. Venus to make sure whether it is not a good old sort named Cook's Early, which has been grown in this locality for the last thirty years. As I understand, it was selected from Cook's Early. I myself feel certain it is nothing else than Cook's Early, which I have grown for years, and I believe I am the possessor of a better selection of Cook's than Mr. Venus, which is now in the hands of a first-class seedsman, and has been sold by them as Cook's Early for the last year at the usual retail price for Cabbage seed, it being one of the four varieties I exhibited at the meeting of the Fruit Committee in London on the 10th February last, and for which I received a vote of thanks. I herewith send you a few for your inspection, and I may say that I never had a single plant that bolted, when all other varieties have done so more or less.

The variety in question was sent out by Mr. Cook, who was gardener thirty years ago to Mr. Collingwood, Dissington Hall, Newcastle-on-Tyne, and I believe he sold the stock to Mr. Dewar, seedsman, Newcastle-on-Tyne, and has remained ever since almost a local Cabbage.

I am growing eighteen varieties this year, and intend sending a collection next spring to the Committee in London, and would suggest that Mr. Venus also send some of his for inspection, as I think it would be to the interest of the public to know before it is distributed whether it is a new or old variety.—DAVID INGLIS, *Howick, Lesbury, Northumberland*.

[Under whatever name this Cabbage may be grown we can testify from the specimens we have received that it is a variety of great excellence.]

CHESTERFIELD ROSES.

THE ancient town of Chesterfield boasts, amongst other attractions, of a church with a remarkable twisted spire. To a large number of travellers in this district probably the crooked spire is the only symbol by which they remember the town. The Derbyshire farmer is interested in its good market, and the rosarian and florist in the good Roses that are

grown and sent out, both plants for stocking the rosary, &c., and cut blooms for the exhibition table.

Having received an invitation from Mr. R. W. Proctor to inspect his nursery I took an early opportunity to run over and see, more particularly his stock of Roses, which I found to be an exceedingly good one. The soil in that portion of the nursery devoted to Rose cultivation is rich, felt slightly springy to the tread, and rests upon a bed of clay. I noticed a little hair, lime, and spent bark, indicative of the refuse of the tannery, peeping out of the soil in places. The elasticity of the soil may be due to the particles of hair, which is doubtless beneficial in strong or clayey soils. The Roses are planted in rows, and have a south-western aspect partially screened from the north winds. They are young plants full of strength, some of this season's growths being over 7 feet long, many about 5 and 6 feet, of strong firm wood. There were not many blooms open, but fine hard buds were plentiful. All the best varieties are grown, and with one or two exceptions are budded low down on the Briar stock, and when transplanted the base of the new growth would be below the surface of the ground, the result doubtless of causing many varieties to emit roots of their own from the base of the young shoot. Mr. Proctor has taken many first prizes for cut Roses at Sheffield, Handsworth, and most other local exhibitions. In passing through the nursery I noticed several beds of fine seedling Carnations containing many good varieties. There were also beds of healthy double Pyrethrums, which are somewhat of a specialty here, but at this time of the year the most attractive beds were made up of *Anemone japonica*, alba and rubra, both very floriferous. These plants are very serviceable for cut blooms at a time when the outside beds are getting very bare and forlorn, and are not, I think, seen in the open border as often as they should. In most large towns, particularly on Saturday nights, large numbers of bouquets and buttonhole flowers are sold, but in my ramble through the town and marketplace I saw very few flowers for sale, and concluded that their absence indicated a lack of interest in the working population for floral decorations. Chesterfield can boast of a few good florists who are successful cultivators. Let us hope that their example may be the means of stimulating in the inhabitants a love for that delightful occupation, floriculture.—J. H. S.

MR. E. MOLYNEUX.

WE consider this a fitting opportunity to present to the public, and more particularly the great body of Chrysanthemum growers, a portrait of one who has achieved such remarkable success in the culture of these flowers.

Mr. Molyneux was born near Helmsley, Yorkshire, his father at that time being gamekeeper to the Earl of Feversham, Duncombe Park, but the subject of this sketch evidently inherits some of the floral tastes of his grandfather, who lived for over forty years as gamekeeper at Nuneham Park, Oxford, where he was an ardent cultivator of florists' flowers, and was a successful exhibitor at many London and local shows, notably Oxford, where he frequently contended against the late Mr. C. Turner of Slough, and not always came off second best. Dahlias were his principal hobby, and he was the raiser of the "Nuneham Park" Onion.

We believe that Mr. E. Molyneux was never employed in a garden where Chrysanthemums were grown, except in the ordinary decorative way, neither has he had anyone to "coach" him; but seeing the splendid flowers produced by the Liverpool growers, and being impressed with their excellence, he was animated with a desire to equal them, and well he has succeeded, as his record will show, in winning such a large number of prizes in the best competition. This should be very encouraging to other young growers who desire to emulate him. He is a close observer of all small details in connection with the growth of the Chrysanthemum never over-estimating his own produce. He has received most valuable assistance from his brother, Mr. N. Molyneux, and from the young men employed under him, without which, he desires us to say, it would have been most difficult to achieve what he has done. He considers that by acting kindly, yet firmly, to those under him, he has contributed to his success. He receives much encouragement from his employer, W. H. Myers, Esq., who is a thorough enthusiast in all matters connected with the garden, which is admirably managed in every department, fruit and vegetables being produced in first-rate condition.

We presume that Mr. Molyneux, now having achieved his object in the challenge cup competition, will, in a series of articles, detail his practice for the benefit of others, as his experiments must now be about completed.

The following is the record of prizes won by Mr. Molyneux, and speaks for itself.—1880, Southampton, four firsts. 1881, Richmond, two first, one second; Southampton, two firsts and two seconds; Kingston, one first and one third. 1882, Southampton, five firsts; Kingston, five firsts, including the champion cup, and one second. 1883, Southampton, six firsts; Kingston, seven firsts, including the champion cup; Win-

chester, four firsts. 1884, Southampton, six firsts; Winchester, five firsts; Kingston, six firsts, including the champion cup, and two seconds. 1885, Southampton, one first; Crystal Palace, seven firsts, one second, and one third; Kingston, eight firsts, including the champion cup for the fourth consecutive time, one second, and one third; Winchester, five firsts and one second. This represents the astonishing total, in six years, of eighty-six prizes, seventy-four of which were firsts. Comment on such a record is needless.

CHRYSANTHEMUM SHOWS.

WEYBRIDGE.

THE eleventh annual Exhibition of the Walton, Weybridge, Oatlands, and Hersham Chrysanthemum Society was held in the Village Hall,

In the open class of twenty-four, incurved blooms, distinct, the competition between Mr. Carpenter, gardener to C. J. Abbott, Esq., Walton, and Mr. Burns, gardener to H. A. Rigg, Esq., Hersham, was very close, but the former won the foremost place by the freshness, symmetry, and solidity of his flowers, Mr. Burns staging some larger, including grand examples of John Salter, Lord Alcester, and Empress of India. Mr. Carpenter staged—back row—Princess of Wales, Lord Wolseley, Lord Alcester, Queen of England, Golden Empress, John Salter, and Golden Queen. Second row—Guernsey Nugget, Mr. Brunlees, Refulgence, Princess of Teck, Baron Beust, Lady Hardinge, and Barbara. Front row—Bronze Jardin des Plantes, Jeanne d'Arc, Prince Alfred, Mrs. W. Shipman, Mr. Jay, Venus, Cherub, and Eve; a fresh, even, excellent stand. In the members' class for the same number of incurved blooms Mr. Carpenter was again first; Mr. Plowman, gardener to C. L. Lavers Smith, Esq., Walton, a good second, and Mr. Burns third. Seven stands of twelve incurved blooms were staged, Mr. Goddard, gardener to C. Humby, Esq., Hersham, securing the first position with remarkably neat and well-finished examples of Empress of India, Golden

Fig. 69.—MR. E. MOLYNEUX.

Weybridge, on the 12th inst., and in the cut bloom department especially was a great success. The Society is fortunate in having as its President and Treasurer such excellent patrons of horticulture as H. Cobbett and H. A. Rigg, Esqs., and also many other supporters; the well-known and much-respected names of G. F. Wilson and James McIntosh, Esqs.; indeed the subscriptions equal the sum that is offered in prizes, "gate money" being relied on for meeting other necessary expenses.

Cut blooms, as above intimated, demand primary notice. So good were they, that but for Mr. Molyneux's exhibits the display would have been quite equal to that at Kingston, and there can be little doubt if Mr. Carpenter had concentrated his strength on the twenty-five-guinea cup class there, he would have equalled, if not displaced, Mr. Gibson. His blooms were characterised by symmetry, solidity, and "finish"—qualities that are bound to tell over mere size if accompanied by looseness. But to the classes.

Empress, Golden Queen, Lord Alcester, Mr. Jay, Beauty, Mrs. Shipman, Mr. Brunlees, Jeanne d'Arc, Empress Eugénie, and Prince Alfred. Mr. Millican, gardener to H. Cobbett, Esq., was a close second with larger but looser blooms, and Mr. Gardener, gardener to R. H. Turner, Esq., Walton, third with particularly neat flowers.

Japanese blooms were of great excellence, producing a brilliant display. In the class for twenty-four varieties Mr. Carpenter secured the first place with, in the back row—Elaine, Comte de Germiny, Meg Merrilees, Madame C. Audiguier, Fair Maid of Guernsey, Baronne de Prailly, Boule d'Or (grand), and Mdlle. Lacroix. Second row—Mons. Henri Jacotot, Hiver Fleur, M. Delaux, Soleil Levant, Garnia, Madame Eugène Pourquie, Album plenum, and M. Burnet. Front row—Thunberg, Daimio, Duchess of Albany, La Nègre, Criterion, Mons. Ardène, J. Delaux, and Peter the Great. Mr. Burns was an exceedingly close second, and Mr. Plowman third. Six stands were arranged in the class for twelve varieties, Mr. Goddard winning the

first prize with fresh bright full blooms of Japonais, Val d'Andorre, M. Burnet, J. Delaux, Mad. C. Audignier, Mdle. Lacroix, Marguerite Marrouch, Meg Merrilees, Album plenum, Soleil Levant, Hiver Fleuri, and a grand bloom of Etoile du Midi. Mr. Millican, gardener to H. Cobbett, Esq., was only one point behind, staging among others grand examples of Boule d'Or, Meg Merrilees, and Balmorean.

Mr. Carpenter was once more to the fore in the class for reflexed flowers with splendid examples; Mr. Plowman a good second, and Mr. Millican a close third. In the large-flowered Anemone class the prizes fell to Messrs. Carpenter, Plowman, and Millican for stands of nearly equal merit. Mr. Plowman staged the best Anemone Pompons, one of the most beautiful stands of the season, followed by Messrs. Millican and Lavey. In the class for Pompons Mr. Plowman was first, Mr. Lavey second, and Mr. Millican third; but it is a question if all the varieties staged were Pompons, and the Judges, assuming they represented the intentions of the Committee, awarded the prizes to the best stands.

"Three Friends" provided the means for offering prizes for the best six blooms of incurved and best six of Japanese of any one variety. The response was most satisfactory. In the incurved section Mr. Burns won with grand examples of Lord Alcester, Mr. Carpenter being second with Empress of India, and Mr. Goddard third with Jeanne d'Arc. Japanese.—First, Mr. Burns, with remarkable blooms of Mdle. Lacroix; second, Mr. Reeves, with about equally fine examples of Madame C. Audignier; third, Mr. Carpenter, with Fair Maid of Guernsey.

Plants.—In the class for six dwarf-trained Mr. Plowman was first, fine specimens, but not quite in perfection, and sticks too obtrusive; Mr. Millican second with smaller and better flowered examples; third, Mr. Lavey.

In the class of four plants Mr. Cante was the only exhibitor of good specimens. He had also the best of two standards, Mr. Millican having the best four with stems $3\frac{1}{2}$ feet high and beehive-like heads, with nearly 100 flowers; he also secured the chief prize for dwarf Pompons, Mr. Plowman showing the best standard Pompons.

The President's prize for two plants worked with not less than two varieties, and for six large-flowering on single stems untrained, were obtained by Messrs. Plowman and Millican, who each had at least four varieties flowering on each plant. The President's prize for six untrained plants and the Treasurer's prize for a similar number, not to exceed 3 feet 6 inches in height, and also untrained, were well won by Mr. Reed, gardener to E. Petit, Esq. Mr. Goddard staged the best Primulas and Mr. Reeves the best table plants, among them Aralia Chabrieri and Jacaranda mimosæfolia, showing how well they are adapted for this purpose. Mr. G. Masters continues the Secretary of this excellent Society, and the value of his services has been recognised by the members.

WESTON-SUPER-MARE—NOVEMBER 12TH.

THE first Exhibition of this newly formed Society was a decided success, and under the able management of Mr. W. Pain, and an active committee of gardeners and amateurs, there is no doubt the autumn Show will soon attain to the same importance as that held during the summer. A fairly liberal schedule was framed, but as it was decided to localise the competition the number of exhibitors was somewhat limited, and next season with various open classes, as well as the experience gained by local growers, we may safely anticipate a great advance in both numbers and quality of the exhibits. The Victoria Hall is well adapted for such a show, but at times was scarcely large enough to hold the numerous visitors. The best six plants of large-flowered varieties of Chrysanthemums were staged by Mr. W. Brooks, among these being very creditable specimens of Mrs. Dixon, Gloria Mundi, Plenipo, and Mrs. Glenny; Mr. W. Hughes, gardener to H. Pethick, Esq., was a close second, his best being Julia Lagravère, Pink Christine, and Jardin des Plantes. Mr. W. Holland, gardener to W. Ash, Esq., was first with four specimens in which Japanese varieties were admitted, having untrained freely flowered plants of Mrs. Rundle, Mr. Glenny, Source d'Or, and Elaine; Mr. W. Horstman was second, and Mr. J. Matthews, gardener to S. S. Knyfton, Esq., third. Mr. W. Brooks was easily first with four plants of Japanese varieties, these consisting of beautifully flowered Bouquet Fait, Source d'Or, James Salter, and Baronne de Prailley; Mr. W. Hughes was second. Mr. Brooks was also successful with trained Pompons, standard large-flowered varieties and pyramids, other successful exhibitors being Messrs. H. B. Farington, W. Holland, and W. Hughes. The best group of miscellaneous plants was arranged by Mr. S. J. Day, gardener to W. P. Emerton Esq.; Mr. Brooks being second, and Mr. H. Hughes third; and with other plants and Ferns Messrs. W. Holland, W. Brooks, S. J. Day, and H. Hughes were the principal prizewinners.

Many of the cut blooms shown were most creditable to the growers, some of whom were amateurs, but all the incurved especially would have been improved by a little "cupping up" and "dressing." With twelve incurved Mr. W. Brooks took the lead, his best blooms being of Golden Empress of India, Jardin des Plantes, Nil Desperandum, Prince Alfred, Princess of Teck, and White Venus. Mr. W. Hughes was a close second, his best being Empress of India, Chernb. Barbara, and Empress Eugénie. Mr. Ash staged the best six incurved, Empress of India, Princess of Teck, and Venus being the most perfect; Mr. H. Horstford was a good second, and Mr. E. J. Day third. Mr. W. Hughes was first with twelve Japanese, his stand including Fair Maid of Guernsey, Baronne de Prailley, Bronze Dragon, Yellow Dragon, and Comtesse de Beauregarde in good condition; Mr. W. Brooks was a close second, and Mr. J. Fox a good third. The last two were respectively first and second with Anemone-flowered varieties. Mr. W. Brooks had the best bouquet; Mr. S. J. Day being second, and Mr. W. Pain third, all showing creditably; while Messrs. Brooks, Hughes, and Pain had the best epergnes of choice flowers. The last named arranged an extensive display of dried natural Grasses and artificial wreaths, as well as lovely wreaths and crosses of natural flowers and Ferns, not for competition, and which fully deserved the admiration bestowed upon them.

The display of fruit was not a large one, but included good examples of Grapes, Apples and Pears. In the class for black Grapes Mr. W. Daffurn, gardener to Mrs. H. T. Walker, was easily first with very well finished Alicante; Mr. T. Palmer being second with the same variety, and Mr. E. J. Day third, each showing creditably. Mr. W. Daffurn staged, but not for competition, three grand bunches of Gros Guillaume, these weighing in the aggregate about 18 lbs., and were beautifully finished, and the Judges

recommended that a special prize be awarded for them. With four dishes of Pears Mr. E. J. Day was first, and Mr. Knight second. The best single dish of Pears, Marie Louise of good size, was staged by Mr. E. Wheeler, gardener to Miss Charrington; and Mr. C. Rowe, gardener to J. C. Capel Cure, Esq., was a good second with Benrre Diel. Mr. J. Tilley, gardener to Col. Cotgrave, was first with four varieties of dessert Apples, and Mr. J. Matthews second, the last named being also successful with four varieties of culinary sorts. The best single dish of culinary Apples, Warner's King in good condition, was shown by Mr. J. Jakeway, and Mr. E. J. Day was second. Several very excellent collections of vegetables were shown, Mr. J. Tilley being a good first with really fine dishes of Veitch's Autumn Giant Cauliflower, Sutton's new Intermediate Carrot, Magnum Bonum Potatoes, Sutton's Sulham Prize Celery, good Seakale, Perfection Tomatoes, White Stone Turnips and Onions; Mr. J. Day was a creditable second, and equal thirds were awarded to Messrs. W. Hughes and W. Jullick.

BATH.—NOVEMBER 11TH AND 12TH.

ALTHOUGH as far as specimen plants were concerned this Exhibition scarcely equalled preceding ones, it was, on the whole, highly successful, and it is to be hoped would to a certain extent lessen the ill effects of the great loss experienced by the Bath Floral Fêtes Committee at the September Show. So well attended was this Chrysanthemum Show that we were unable to take a detailed report, especially of the classes for cut flowers, while it was no easy matter to critically examine the grand lot of fruit and vegetables in competition.

The best six trained large-flowered Chrysanthemum plants were exhibited by Mr. E. Silcox, gardener to W. Vowles, Esq., these consisting of Venus, Mrs. Rundle, Lord Derby, Empress of India, Mrs. Dixon (this plant gaining silver medal of National Chrysanthemum Society), and Princess of Wales, all in fairly good condition; the second prize going to Mr. J. C. Morris, gardener to R. B. Cater, Esq., who had a very creditable lot; and Mr. G. Tucker, gardener to Major W. P. Clarke, was third. In a corresponding class for four plants Mr. R. W. Southard, gardener to F. J. Walker, Esq., was first, Mr. Henry Scott second, and Mr. A. A. Walker third, some of the specimens shown being very praiseworthy. The first prize for three standards trained was awarded to Mr. W. Taylor, gardener to S. P. Budd, Esq., who was followed by Mr. W. J. Browne, both exhibiting creditably; and Mr. H. Marchant, gardener to T. Jolly, Esq., was third. A grandly flowered plant of Mrs. Rundle staged by Mr. J. Lee, gardener to T. M. Miller, Esq., gained that exhibitor the first prize for a single specimen and also a special prize of £2 2s. Equal seconds were awarded to Messrs. Silcox and J. Morris, the former having a good plant of Mrs. Rundle, and the latter a huge flatly trained Japanese Peter the Great. The latter exhibitor was also first for a pyramid of the same variety, and Mr. Silcox was first for a pyramid Pompon. The best six trained Pompons were staged by Mr. Tucker, but these and the other exhibits in that class gave evidence of the severity of the early frosts experienced. The first prize for six trained Japanese was awarded to Mr. W. J. Brown, who had Hiver Fleuri, L'île des Plaisirs, Album Plenum, Duchess of Albany, Madame Bertie Rendatler, and Mons. Plancheneau in excellent condition. Mr. J. Southard was second, and Mr. W. Nash third. With six conservatory plants the prizewinners were Messrs. J. Morris, E. Silcox, and A. Hawkins, who were placed in the order named, all having formally trained plants of incurved sorts. A special prize of £5, offered for six Chrysanthemums, three to be incurved and three Japanese varieties, combining best foliage and bloom with natural growth, was well won by Mr. J. Southard, who had medium-sized freely flowered examples of Prince Alfred, Golden Empress, Queen of Whites, Peter the Great, Madame Bertie Rendatler, and an unnamed variety. Four fine groups of Chrysanthemums were arranged, all being nearly equal in merit, and as a consequence the Judges' decisions were not generally considered satisfactory. Mr. Gay, gardener to L. Daubeny, Esq., was placed first, his group comprising much the finest blooms, though these were not so plentiful as in the other groups. Mr. J. Morris was a good second, Mr. W. Taylor third, and certificate of merit was awarded to Mr. A. A. Walters.

Classes were also provided for various flowering and fine-foliage plants, and in every case the competition and quality of the exhibits was good. The best miscellaneous group was arranged by Messrs. Cooling & Son, Bath, who had an excellent assortment of fine-foliaged and flowering plants, rather too neatly arranged, however, the pots being somewhat conspicuous. Mr. W. C. Drummond was second, his group including larger plants, but lacking finish in the arrangement; and the third prize went to Mr. T. M. Miller. Bouvardias were well shown by Messrs. G. Garraway, E. Miller, gardener to F. Tagart, Esq., and Messrs. Cooling & Son; Poinsettias by J. Durbin, gardener to J. Tredwell, Esq., E. Miller, and B. Hopkins, gardener to John Bailly, Esq., Frome; Cyclamens by Messrs. A. A. Walters and G. Garraway; Primulas by Mrs. Walker, Mr. H. Lord, and Mrs. Howe; six ornamental-foliaged plants by Messrs. W. C. Drummond, E. E. Bryant, and H. Mardon; and table plants by Messrs. G. Cooling & Son, E. Miller, and B. Hopkins, who received the prizes in the order named in each instance.

There was a marked increase in the number of cut blooms in competition, and in many cases the quality was good, though not yet up to the form displayed at the shows held around London. In the class for twenty-four blooms of large-flowered varieties in not less than twelve varieties there were about twelve competitors, the first prize going to Mr. C. W. Cook, gardener to J. Taylor, Esq., Cirencester, whose stands included excellent examples of Queen of England, Jeanne d'Arc, J. Salter, Lord Alcester, Princess of Wales, Mrs. Heale, Prince Alfred, Nil Desperandum, Jardin des Plantes, Princess Teck, Lady Hardinge, and Mrs. Rundle. Mr. E. Miller was second, several rough blooms somewhat marred his exhibit; and Mr. W. Iggulden third, the latter's stands including rather too many whites; and Mr. J. Marshall was highly commended. The class for twelve blooms, from which exhibitors in the preceding class were excluded, was a poor one. Mr. Gay was first and Mr. R. Richards second, while for six blooms Mr. Waite was first, B. Hopkins second, and W. Taylor third. There were eleven stands of twelve Japanese blooms, the majority of them being meritorious. Mr. W. Iggulden was placed first, his stand including fine fresh examples of Fair Maid of Guernsey, Madame C. Audignier, Thunberg, Comte de Germiny, Belle Paule, Val d'Andorre, J. Delaux, Meg Merrilees, and Grandiflorum; Mr. E. Miller was a close second, and Mr. J. Marshall

third. The best twelve Anemone-flowered were staged by Mr. E. S. Cole, gardener to W. Pethick, Esq., who had good blooms of Madame Berthie Piguy, Sœur Dorothee Souille, Lady Margaret, and Empress; Mr. E. Miller was second, and Mr. H. Derham third. The latter was first for eighteen blooms in six varieties, and shown with long stems and foliage, Mr. Gay being second, and Mr. J. Hobbs commended. The best stand of twelve incurved in four distinct colours was shown by Mr. E. W. Cook, Queen of England being very fine; Mr. J. Marshall was second, and Mr. H. Derham third. Mr. F. Hooper was first with Pompons, Mr. H. Hooper second, and Mr. Jolly third. The silver medal of the National Society for best bloom in the Show was awarded to Mr. W. Iggulden for a fine example of Empress of India. Vases and bouquets of cut flowers and baskets of autumn leaves and berries were shown in the usual excellent manner, the latter being very numerous and beautiful, and with these Mr. G. Head was first, Mr. E. T. Hill second, and Miss H. Ashman third. The prizewinners with bouquets were Messrs. G. Garraway, W. H. Mould, and Mr. E. Thomas; and with vases Messrs. E. T. Hill, H. Mardon, and E. S. Cole.

It is in the fruit section where the Bath Show is in advance of the majority of kindred societies, Grapes, Pears, and Apples being the most conspicuous. The prizes are by no means liberal, and a considerable number of fruiterers invariably take a proportion of the prizes, but in spite of these drawbacks a grand show of fruit and vegetables was formed. With a collection of six varieties of fruits Mr. W. Nash, gardener to the Duke of Beaufort, was placed first, his Alicante and Muscat of Alexandria Grapes, Golden Gem Melon, Medlars, Hacon's Incomparable Pears, and Harding's Nonesuch Apple being all very good. Mr. W. Iggulden was a close second, his collection including a good dish of Bananas, Doyenné du Comice Pears, and Alicante Grapes. The third prize was won by Mr. W. Bannister, gardener to H. St. Vincent Ames, Esq. Mr. Nash was easily first for four bunches of Grapes in two varieties, having fine bunches of Alicante and fairly good Muscat of Alexandria. Mr. W. Taylor, gardener to Alderman Chaffin, was a good second, his bunches of Alicante and Gros Colman being rather small but well finished. Mr. Nash was also first in the class for any black Grapes, but was somewhat favoured, as his bunches of Alicante, though very fine, were not well coloured. Mr. W. Taylor was again second with the same variety, small in bunch, but beautifully finished; and Mr. E. Chedzey, gardener to W. Duck, Esq., was third with fine bunches of Alicante, which many seemed to think should have been first. Not many white Grapes were shown, Mr. J. Ellicott, gardener to H. W. Tugwell, Esq., being easily first with beautifully-coloured Muscat of Alexandria; Mr. G. W. Shelton, gardener to W. K. Waite, Esq., being second with the same variety. There were nine lots of six varieties of Pears staged, and in this class the Judges followed the rather unusual course of awarding the prizes to the generally evenest in appearance, all being fit for the table, and as a consequence much the finest collection, staged by Mr. W. Bannister, was passed. Mr. W. J. Smith was placed first with fairly good dishes of Marie Louise, Louis Bonne of Jersey, Benrre Bosc, Beurre diel, Beurre de Capiaumont, and Beurre d'Aremberg. Mr. E. Smith was second, and Mr. E. Hall third. Sixteen collections of four dishes of Pears were staged, Mr. F. Lord leading with Marie Louise, Glou Morceau, Beurre Bosc, and Duchesse d'Angoulême. Second Mr. W. Bodman. Third Mr. W. Bush. Thirty-four entered in the class for one dish of Pears, Mr. A. Hall winning first prize with Marie Louise, Mr. Bush following with the same variety; and Mrs. Howe was third. Dessert Apples were very numerous and well shown, such sorts as Cox's Orange Pippin, King of Pippins, Kerry Pippin, Blenheim Pippin, Ribston Pippin, and Cornish Gillyflower being the most popular. Mr. G. Hallett was first with six varieties; Mr. Garraway second; and Mr. E. Hall third, while other successful exhibitors of Apples were Messrs. Biss, F. Ford, W. Evry, W. Webber, W. J. Smith, H. Taylor, Mrs. Deane, and Col. Grant. The collections of vegetables were highly creditable, immense heaps of the different sorts being shown. The prizewinners were Messrs. Garraway, T. Evry, and W. Tylee.

LEICESTER.

The sixth annual Show of this Society was held last week at the Freeman's Arms Hotel, Aylestone Road, and was opened by the Mayor (Alderman Hart). The room was tastefully decorated with evergreens and flowers by Mr. W. J. Iliffe, florist, Market Street. The table decoration of Mr. W. J. Iliffe was very highly commended by the Judges, and awarded a special prize; and plants for decoration were kindly lent by Mr. G. Boyes, Aylestone Park, Mr. John Sargent, Mr. J. Read, Mr. H. Jordan, Mr. J. Burn, and Mr. J. D. Harris. The blooms were a great advance on last year, and special mention should be made of a box of eighteen incurved of Mr. S. Collett, which was deservedly awarded the first prize, and which contained splendid specimens of the Empress of India, Lord Wolsley, General Slade, Refulgence, John Salter, and Golden Empress. Mr. Collett's box of twelve Japanese also obtained the honours—viz., Lady Selborne, James Salter, and Madame Audiguer. The three blooms in Class 7—viz., Lord Wolsley, Empress of India, and Prince Alfred—were especially fine, for which Mr. Collett obtained the first prize. Mr. R. A. Rundel of London exhibited for non-competition a box of Pompons, and also a box of incurved varieties, which were very fine. Mr. H. Woodfield of Thurmaston Pottery exhibited a collection of fancy pots, and Mrs. Grocock several baskets of dried flowers. The Judges were Messrs. G. R. Faire, Barkby; Mr. John Bunn, Abbey Park; and Mr. A. Angus. The Mayor complimented the Secretary upon the result of the Show, and said great credit was due to him for the efforts connected with the working and carrying out in such a successful manner the arrangements. At least 2000 persons visited the Exhibition during the afternoon and evening.

The following is the prize list:—

Open to all England.—Class 1 (eighteen blooms incurved, distinct varieties).—First, S. Collett; second, C. Kitchings, gardener to W. B. Paget, Esq.; Class 2 (twelve blooms incurved, distinct varieties).—First, C. Kitchings; second, Landsell, gardener to Thomas Brooks, Esq., Barkby Hall. Class 3 (twelve blooms, Japanese, not less than six varieties).—First S. Collett; second, Landsell; third, C. Kitchings.

Open to Amateurs within Four Miles of Leicester.—Class 4 (twelve blooms incurved, distinct varieties).—First, S. Collett; second, Jno. Bird. Class 5 (six blooms incurved, distinct varieties).—First, S. Collett; second, R. Maine; third, H. Bell; fourth, F. Saun; fifth, C. Day; sixth, H. Jordan;

seventh, C. Scotney. Class 6 (six blooms Japanese, not less than three varieties).—First, S. Collett; second, H. Bell; third, F. Saunt; fourth, A. Maine; fifth, H. Jordan. Class 7 (three best incurved blooms, distinct varieties).—First, S. Collett; second, C. Day; third, A. Maine; fourth, H. Bell; fifth, John Bird; sixth, F. Saunt. Class 8 (basket of Chrysanthemums).—First, S. Collett; second, A. Maine; third, C. Day. Class 9 (bouquet of Chrysanthemums).—First, H. Jordan; second, John Sargent; third, Mrs. Grocock. Class 10 (three best plants).—First, H. Jordan; second, John Sargent; third, John Bird. Class 11 (best single plant).—First, H. Jordan; second, John Sargent; third, John Bird. Class 12 (best single bloom, any variety, staged separately).—First, S. Collett.

GRAVESEND AND NORTH KENT.

The twelfth annual Exhibition of the above Society was held in the Milton Hall on the 11th and 12th inst., and was as usual well patronised. The first prize for twenty-four cut blooms, incurved, was gained by Mr. Phillips, The Deodars, Meopham, Kent; the first for twenty-four blooms Japanese going to the same exhibitor; the first for twelve blooms of incurved to Mr. Armstrong, gardener to N. S. Dunbar, Esq., Greenhithe. The majority of the first prizes for trained plants was won by Mr. Richardson, gardener to Sir James Fergusson, Bart., Singlewell. In the fruit classes Mr. Phillips was first for the collection of eight varieties; Mr. Armstrong securing the first for three good bunches of Grapes, Alicante. Mr. Findly, gardener to Willowby Brown, Esq., staged not for competition three large bunches of Grapes, Black Alicante, the largest bunch weighing 8 lbs. The collections of vegetables were superb, the first prize going to Mr. Phillips, the second to Mr. J. Pope, gardener to John Russel, Esq. Among the miscellaneous exhibits were some fine Chrysanthemum blooms, shown not for competition by Mr. W. Etherington, The Gardens, Swanscombe, Kent. One board which attracted great attention contained new Japanese varieties M. Ghye, clear gold frosted silvery white; Souvenir de Haarlem, violet centre, reverse yellow, very large; M. J. H. Laing, creamy white, yellow centre; Jupiter, fiery red, shaded crimson; M. Garnier, orange, shaded chestnut; L'Aube Matinale, salmon red, shaded gold, very fine; Eugene Mizard, amaranth, gold centre; M. A. Vilmorin, crimson orange and gold; M. Vintouski, crimson and chamois, shaded brown; L'Adorable, very large, canary yellow, shaded violet and red, a fine bright variety; Cœur Fidele, silvery white, shaded violet rose, very fine light variety. The arrangements were all that could be desired, and great credit is due to the Secretary, Mr. Fairey.—S.

PORTSMOUTH.—NOVEMBER 12TH AND 13TH.

The first Exhibition held by the Portsmouth Chrysanthemum Society took place on the dates named above in the new Drill Hall in Alfred Road, a spacious place, well suited to the purpose, there being abundance of room for visitors to wander about and admire the exhibits. Chrysanthemum-growing in this neighbourhood has become very popular judging from the number of entries received for the Show in question. The Hon. Secretary, Mr. F. Power, had spared neither time nor pains to make the Exhibition what it was—a great success. Groups of Chrysanthemums were staged in large numbers and of fair quality, the best coming from Mr. J. Kimber, The Asylum, Wilton; second Mr. T. Short, nurseryman, Southsea. Plants of Chrysanthemums were not of good merit, mostly grown on the old-fashioned principle of tall unstopped plants, which must be lanky specimens under this system of treatment. Of these Mr. J. Byerly, Landport, had the best.

Cut blooms made far the best show, of which there was a considerable number, the competition being keen in the various classes, of which sixteen were provided. A prize of £5 as first for thirty-six blooms, eighteen to be Japanese and same number of incurved, brought out several collections, all of good merit. Mr. W. Neville, gardener to F. W. Flight, Esq., Cornstiles, Twyford, Winchester, was an easy first, his blooms throughout being particularly fresh, of large size, good form, and well staged. Particularly handsome were Japonaise, Mdle. Lacroix, Thunberg, Album plenum, Agrements de la Nature, and Fanny Bouchariat among the Japanese, while among the incurved specimens were Empress of India, Lord Alcester, Princess of Wales, Princess Teck, and Mrs. W. Shipman. Second Messrs. W. & G. Drover, florists, Fareham, who staged very fine flowers of J. Delaux, Triomphe de la Rue des Chalets, Criterion, Hero of Stoke Newington, and Empress of India. Third Mr. C. Penford, gardener to Sir F. Fitzwygram, Bart., Leigh Park, Havant. Mr. Flight again led with twelve Japanese and same number of incurved, with fresh and very neat specimens, followed by Messrs. Penford and Drover. For twelve reflexed blooms Mr. Penford was first, showing superior quality, as also he did in the class for twelve Anemones, his blooms of Empress, Gluck, Fabian de Mediana, and Fleur de Marie being specially noteworthy. Mr. Flight was first for twelve sprays of Pompons, followed by Mr. N. Fuller, gardener to Sir J. C. Jervoise, Idsworth House, Havant. Amateurs showed in strong force with cut blooms, principal among them being The Rev. Wells, Rockhampton, W. Lang, Esq., Havant, and Tucker, Esq.

The best table plants, Primulas and Cyclamens, were staged by Mr. Fuller. Mr. Fuller staged the best Grapes, two bunches of Alicante well coloured. Mr. Fuller was second, he also staging Alicante. For two bunches of white Grapes Mr. J. Read was first and Mr. Penford second, both showing fine produce. For three dishes of Apples and three dishes of Pears Mr. A. C. Smith was first and Mr. J. Taplin was second.

Prizes were offered for the best bouquet of Chrysanthemums and Ferns. Most of them were very much too large. Mr. Short took first prize with a neat arrangement. Mr. Hatch of the Victoria Park, Portsmouth, staged a capital group, "not for competition," consisting of the leading varieties, well grown and tastefully arranged.

CHISWICK.—NOVEMBER 17TH.

THOUGH small, the Chrysanthemum Exhibition held by the Chiswick Horticultural Society in the Vestry Hall, Turnham Green, on the above date, was one of the neatest we have seen this year. The Society is a small one, and not in a position to offer very valuable prizes, consequently the competition in most of the classes was chiefly confined to local growers; but their exhibits on the whole were good, and the schedule of classes was judiciously arranged. Appended are details:—

GROUPS.—Three classes were provided for these, and although no prizes were offered for competition, four handsome collections were staged in Class 1, for a group of Chrysanthemums (any class) to be arranged on a

space not exceeding 60 square feet. The most noticeable of these were that shown by Mr. J. May, gardener to the Marquis of Bute, Chiswick House, Chiswick, which was admirably arranged, and the flowers of exceptionally large size; and that from Messrs. W. Fromow & Sons, The Nurseries, Chiswick, in which the flowers were more plentiful, but a little smaller. Mr. Harding, gardener to J. R. Starling, Esq., The Chestnuts, Gunnersbury, and Mr. Davis, gardener to H. G. Lake, Esq., Fairlawn House, Acton Green, also showed handsome groups. There was only one entry in the class for trained specimens, and also in that for Pompons, Mr. Chadwick, gardener to S. M. Nelson, Esq., Hanger Hill House, Ealing, staging fair plants in each.

CUT FLOWERS.—For eighteen blooms, nine incurved and nine Japanese, Mr. Collyer, gardener to Mrs. Murrell, The Elms, Ealing, was an easy first, showing very fair blooms of the following varieties:—Incurved.—Lord Alcester, Alfred Salter, Empress of India, Hero of Stoke Newington, Barbara, Princess of Wales, Bendigo, Mrs. Heale, and Mrs. Shipman. Japanese.—J. Delaux, Mdle. Lacroix, Mdme. C. Audiguier, Duchess of Albany (Jackson's), Baronne de Prailly, Meg Merrilees, Mons. Astorg, Thunberg, and Mdme. de Sevin. Mr. J. Baird, gardener to C. A. Daw, Esq., Homefield, Ealing, was second, his stand including fairly good blooms of Guernsey Nugget, Princess of Teck, Mdme. Audiguier, and Mdle. Lacroix. The third prize fell to Mr. Davis. E. Sanderson, Esq., St. Mary's Road, Harlesden, was first for twelve incurved flowers, his stand containing good blooms of Lord Wolseley, Emily Dale, Barbara, and Princess Beatrice. The others, though small, were neat. Mr. J. Beasley, gardener to F. A. Fraser, Esq., Eastbourne House, Ealing, and Mr. Long, gardener to E. B. Ridges, Esq., Orchard Dean, Ealing, were placed equal second, the former showing Queen of England, Lord Alcester, and Golden Empress very well, the latter being best represented by Jardin des Plantes (very good), Bronze Jardin des Plantes, Venus, and Mrs. Heale. Equal third was awarded to Mr. Davis and Mr. Stanton, gardener to H. Smith, Esq., Chiswick. Mr. Long was first for twelve Japanese, showing Criterion, Thunberg, Hiver Fleuri, and Mdme. Audiguier well. Mr. Harding and Mr. Woods, gardener to Mrs. Sanderson, Chiswick, were placed equal second, and Mr. Davis and Mr. Stanton equal thirds. For six incurved flowers of one variety Mr. J. Baird was placed first for small but very neat blooms of Barbara; Mr. Collyer second for Bendigo, and Mr. Davis third for Venus. In the corresponding class for Japanese Mr. Long was first with Mdle. Lacroix, excellent blooms; Mr. Harding second with Mdme. Audiguier and Messrs. J. Coombs, The Gardens, Sheen House, Mortlake (Mdme. Audiguier), and Davis (Fair Maid of Guernsey), equal third. Messrs. Chadwick, Collyer, and Beasley were awarded first, second, and third prizes respectively for six Pompons. Some fine blooms were also shown in the amateur classes, and charming bouquets of Chrysanthemums were shown by Mrs. Rust (first prize), Chadwick (second), Baird (third).

PLANTS.—In the class for six table plants Mr. Hudson, gardener to J. Atkinson, Esq., M.P., Gunnersbury House, Acton, was first with nice plants. We observed no other award. Mr. Woods received the premier award for six Primulas, showing good plants; Mr. J. Coombs was a good second; and Mr. Stanton third.

FRUIT.—Four splendid dishes gained the first prize in the class for that number of Apples, with the following sorts:—Golden Noble, Blenheim Pippin, King of the Pippins, and Dumelow's Seedling. The second was awarded to Mr. Chadwick, who also showed fine fruit, the varieties being Hanwell Souring, Ribston Pippin, Blenheim Pippin, and Dumelow's Seedling. Four dishes of Pears.—First Mr. Chadwick, with Glou Morceau, Beurré Diel, Beurré Bosc, and Gansel's Bergamot. Second Mr. Coombs. Finely coloured bunches of Alnwick Seedling were shown by Mr. Hudson in the class for two bunches of black Grapes. There was no competition, and he was awarded first prize. This was also the case in the class for a white variety, good bunches of Muscat of Alexandria gaining him the award. Baskets of black Grapes and large collections of Apples and Pears from the Royal Horticultural Society added a great feature of interest to the Show. For six dishes of vegetables Mr. Coombs was first and Mr. Stanton second. Several handsome groups of plants from Messrs. Fromow & Sons were greatly admired.

BRIGHTON AND HOVE CHRYSANTHEMUM SOCIETY'S SHOW.—NOVEMBER 11TH.

The third annual Show of the above Society came off on the 10th and 11th November, and proved in every respect a brilliant success. In proof of the rapid progress this comparatively young Society is making, it will be sufficient to state that in addition to the Dome (which on the two previous occasions held the exhibits) they have on this occasion filled the greater portion of the large Corn Exchange adjoining. This arrangement is a great improvement both for exhibitors and visitors. The groups—a great feature—were seen to better advantage in the better light of the Corn Exchange, while the greater part of the Dome was left for promenade. The arrangement of the Dome was very effective. The cut blooms were arranged on tables round the room. A handsome trained standard Chrysanthemum was placed in each break in the tables (caused by their circular arrangement) so as to show about a foot above the boxes of cut flowers. These trained specimens, between forty and fifty in number, were part of the general decoration of the room, including a fine mass of Palms and other foliage plants, interspersed with standard Chrysanthemums arranged in the orchestra were contributed by Mr. W. Balchin, nurseryman, seedsman, &c., Brighton. These plants were from their Hassocks Nursery, and the production of such a large number of good plants, and the effective way they were arranged, is highly creditable to their energetic manager, Mr. Richardson.

There was a good competition in the classes for groups, and the quality and brightness of the flowers very good, but in some cases the arrangement was rather formal. Mr. J. Bunney, gardener to W. H. Campion, Esq., Danny Park, Hurstpierpoint, was placed first in both classes with very good groups. For six trained standards, J. Rolfe, gardener to A. G. Atkerman Hatch, Esq., Beauchamp House, Worthing, was placed first with neat plants, models of precision in training, and the brightness of the flowers and the vigorous foliage showed excellent culture. J. Hill, gardener to Marriage Wallis, Esq., Springfield, Withdeane, was second with larger, less formal and well-grown plants. The class for six dwarfs were also good, Mr. J. Hill being first and Mr. Rolfe second. There was a strong and close competition in the leading classes for cut blooms, and for size, finish, and freshness,

and especially the brightness of the colours when seen under the electric light, was particularly noticeable. In the class for forty-eight, twenty-four incurved and twenty-four Japanese, C. Gibson, gardener to J. Wormald, Esq., Morden Park, Mitcham, Surrey, was first, closely followed by Mr. Russell, gardener to Dr. Lewis, Henfield. The other class for cut blooms were equally well contested. Classes 12 and 13 provide for trusses not disbudbed to show 6 inches of stem with foliage above the stand as cut from the plant (one wire support only). This is a step in the right direction, but it can scarcely be said that they were a success, chiefly because of their being crowded on too small boxes. Another year, no doubt, it will be entered into with more spirit.

The fruit on the whole was a good show. The Grapes could scarcely be said to be first-class. Mr. Spottiswood's Muscats, awarded first in both classes, were rather thin, but clean, plump, and well coloured. Mr. Godby staged two lots of Black Hamburgs, was awarded first in open class and second in the "county," and it would have been something wonderful had not the question of judging, lately so well discussed in these pages, cropped up. I think the decision was fair. The competition for Apples and Pears was very good. There were twelve entries in the class for four dishes of dessert Apples, and a like number in the corresponding class for culinary. Mr. Bunney's winning lot in the latter class were very fine, they were Peasgood's Nonesuch, Waltham Abbey, Tower of Glamis, and Dumelow's Seedling.

Much interest was taken in the show of vegetables. The trays were numerous and good. The Carrots and Onions in Mr. Bunney's winning trays were remarkably fine, as were the Cauliflowers in Mr. Duncan's. Brussels Sprouts were rather inferior. A special prize for two dishes of Onions brought a good competition. The irrepressible Mr. Bunney was again first with Deverill's Anglo-Spanish and Bunney's Onion. The latter, I understand, is a variety of his not yet in the trade. It is certainly a splendid Onion and deserves to be put in the hands of cultivators. Nothing, I think, on the vegetable tables attracted more attention than this Onion, and I think it ought to have a more taking name—Bunney's Champion for instance.

The whole arrangements for the Show were excellent, and the Committee and their able Hon. Secretary, Mr. Longhurst, are to be congratulated on their success. The Show was crowded on both days, over 2000 persons having paid for admission on the first day. Promenade concerts were given each afternoon and evening, the Band of Coldstream Guards being in attendance.

BASINGSTOKE.

It would not be easy to imagine a more suitable building for a Chrysanthemum show than the volunteer drill hall at Basingstoke, as it is spacious and well lighted from the roof. The Exhibition to be noticed was held on the 10th inst., and as regards cut blooms was very good indeed; the groups also were of average merit, but the specimen plants were poor; in fact, there appears to be a general falling off in these at the majority of shows this year. The first-prize group of Mr. T. Holdaway was in every respect meritorious, while those of Messrs. Champion and W. Thompson, gardener to Capt. Boland, were creditable arrangements. Of the specimen plants it need only be said that the best large-flowered were staged by Mr. J. Dauncey, and the best Pompons by Mr. Thomson.

CUT BLOOMS.—Of these there was an excellent display. The leading class was that of twenty-four blooms distinct, eight Japanese (in the back row), and sixteen incurved. Four lots were staged, J. W. Flight, Esq., Twyford, Winchester (Mr. Neville, gardener), well winning the first prize with Japanese—Balmorean, Comte de Germiny, Striatum Perfectum, Mdle. Lacroix, Baronne de Prailly, Margaret Marronch, M. Astorg, and Japonaise; incurved—John Salter, Alfred Salter, Empress of India, Prince Alfred, Lord Alcester, Princess of Wales, Lord Wolseley, Jeanne d'Arc, Hero of Stoke Newington, Golden Empress of India, Beethoven, Mr. Bunn, Mr. Brunlees, Princess of Teck, Queen of England, and Mrs. Shipman. With few exceptions the blooms were of excellent quality, John Salter, Empress of India, and Jeanne d'Arc being very superior. The second prize was awarded to Mr. J. Bowerman, gardener to C. Hoare, Esq., Hackwood Park, for extremely fresh and neat examples; Mr. Holdaway, gardener to Major J. M. Hawkfield, third, with larger examples. In the class for twelve incurved blooms Mr. Flight distanced all competitors both in size and quality of blooms. Mr. Bowerman was again second; and Mr. Knellen, gardener to Wyndham Portal, Esq., Malshanger, third.

Excellent stands of Japanese blooms were staged, Mr. Flight being again in the premier position in the class for twelve blooms, Agreement de la Nature being in superb condition; a beautiful bloom like a mass of gold threads. Mr. Holdaway was a good second; and Mr. Dauncey, gardener to J. Bramston, Esq., Buckfield, third, with not large, but fresh and bright examples. The prizes offered for twelve blooms in eight varieties to exhibitors who had not previously won a prize were won by Mr. T. Holdaway and Mr. T. Chapman, gardener to Col. Knatchbull, Clatford, Andover, respectively.

In the miscellaneous classes Primulas were very well shown by Messrs. T. Weaver (Oakley Hall), J. Bowerman, and W. Thompson, and table plants by Messrs. Bowerman, Kneller, and Best in the order named. The best black Grapes (Alicante) were staged by Mr. Best, Messrs. Weaver and E. Crump, the successful exhibitors of Muscats being Messrs. Weaver and Bowerman. Kitchen Apples were admirably represented, Messrs. Chapman, Kneller, and Bowerman securing the prizes. Dessert Apples were also numerous and good, the prizes falling to Messrs. Thompson and Weaver in the order named. Messrs. Bowerman, Chapman, Thompson being the successful exhibitors of Pears.

Vegetables were splendidly shown, and never perhaps were five collections seen more equal in merit. It was only by careful point judging that a decision could be arrived at, and the totals were 37, 36, 35, 35, and 34; the first prize fell to Mr. Bowerman, who staged Cauliflowers, Brussels Sprouts, Mushrooms, Canadian Wonder Beans, Potatoes, Onions, Tomatoes, and Celery, the last two only a trifle weak; the second to Mr. J. Dauncey, who had splendid Onions, Potatoes, Brussels Sprouts, and good Carrots, Tomatoes, Beans, and Cauliflowers; equal third prizes fell to Mr. G. Best, gardener to C. W. Chute, Esq. (grand Carrots, Cauliflowers, and Potatoes), and to Mr. R. Lye, gardener to W. H. Kingsmill, Esq., Sydmon Court, Newbury, who had fine Celery, a remarkable dish of Asparagus, and other

excellent products. There remained one other collection, that of Mr. Kneller, which included splendid Onions, Cauliflowers, and large Brussels Sprouts, and other vegetables so good that the Judges were constrained to put their hands in their pockets and in that way provide an extra prize. The Committee are to be congratulated on their Show, and the Secretary, Mr. A. E. Holdaway, on its good management.

FINCHLEY.—NOVEMBER 13TH AND 14TH.

In addition to the usual summer Show the Finchley Horticultural Society this year held an autumn exhibition of Chrysanthemums, fruit, and vegetables on the date above given. The exhibits were not very numerous, and two small school-rooms sufficed to hold them without the slightest approach to crowding, and but for two or three contributions the Show would have been very unsatisfactory, and much inferior to what should be expected from such a district. As a Chrysanthemum Show it was far surpassed by the Lambeth Amateurs' Exhibition and it will be necessary to take some steps to procure a more thoroughly representative display before the Finchley Autumn Show can claim a good place amongst the suburban productions of a similar kind.

The leading stands of cut blooms were contributed by Mr. J. J. Lowry, gardener to J. MacAndrew, Esq., Belmont, Mill Hill, who secured the premier prize with incurved, Japanese, and Anemones, the blooms being similar to those which he had at the Westminster Aquarium on the preceding days. Mr. H. Oliver, Alexandra Green, Finchley, and Mr. H. Mobbs, gardener to W. T. Linford, Esq., Elm Grange, Church End, also showed blooms in several classes. But the most interesting exhibit was, however, a group of Pompon Chrysanthemums from Mr. W. T. Stapleton of Finchley, which included some of the prettiest little plants we have ever seen. They were all in 48-size pots, bushy specimens about 1 foot high, and bearing two to three dozen blooms of the C. do Nulli varieties. The decorative value of such plants could not be over-estimated, and either on the stage of a conservatory or on a margin to groups of plants they would be invaluable. Groups of Chrysanthemums, not for competition, were staged by Messrs. Cuthbush, Williams, and Dixon; Mr. Mohbs also having two tasteful groups.

In the fruit classes the Grapes were the principal exhibits, Mr. P. E. Kay, Long Lane, Finchley, leading in the black Grape class with beautiful examples of Gros Colman, the berries large, the bunches well proportioned and finely coloured. Mr. T. Stapleton was second with Alicantes of excellent colour, and Mr. G. B. Shonlts, Oakley Nursery, Finchley, was third with Gros Colman, very large, but not quite so well finished as the first. Mr. P. S. Kay also had a basket of grand bunches of Alicantes and Gros Colman, not for competition. Mr. J. J. Lowry was first with white Grapes, showing Muscat of Alexandria well ripened. Apples were numerous and Pears were well represented, the principal exhibitors being Messrs. G. Dyke, gardener to H. C. Stephen, Esq., Avenue House, Finchley; J. J. Lowry; H. Jarvis, gardener to H. M. Bishop, Esq., Hendon Park, Mill Hill; Berse, gardener to J. H. Lermite, Esq., Knights, Finchley, and J. Pulling. Two clean collections of vegetables were staged by Mr. G. Agate, gardener to A. Taylor, Esq., Priory House, Southgate, and Mr. Mohbs, who secured the first and second prizes as named.

LINDFIELD.

This Show was held on Thursday and Friday, Nov. 12th and 13th, when there was a grand display of the Autumn Queen, the groups, both gardens and amateur, being exceptionally good, there being some very fine flowers in the first and second-prize lots. The competition for cut flowers was very good; also for extra prizes offered for Apples and Pears, vegetables, &c., by some of the well-known nurserymen. We must not forget the collections of Potatoes staged by Messrs. Sutton & Sons, which were much admired; also numerous other exhibits were sent by the gardeners of the district not for competition. The Show reflected great credit on the Committee and the Hon. Sec. for the arrangements.

The following were the winners of the principal prizes:—For the best group staged for effect.—First, Mr. A. J. Brown, gardener to W. Savill, Esq., Finches; second, Mr. Venn, gardener to W. Sturdy, Esq., Paxhill; third, Mr. Hodges, gardener to S. C. Gibbons, Esq., Walsted; fourth, Mr. Horscroft, gardener to R. Soltis, Esq., Ardingly; fifth, Mr. Braysher, gardener to Mrs. Catt, Leete House. For the best group staged by amateur and single-handed gardeners.—First, Mr. Brook, gardener to Descon, Esq., Lythe; second, Mr. R. Durrant. Twenty-four cut blooms, twelve Japanese twelve incurved (five entries).—First, Mr. Gibbons, gardener to Evans, Esq., The Chalet; second, Mr. Venn; third, Mr. A. J. Brown. Best twelve Japanese (five entries).—Messrs. Venn, Brown, and Hodges in that order. Best twelve incurved.—Messrs. Gibbons, Venn, Hodges, as named. Best six reflexed, six Anemone.—Messrs. Venn and Gower, gardener to Miss Davis. Best single blooms, the prizes given by Mr. Davis of Camberwell (seven entries).—Messrs. Gibbons and Venn. Best incurved.—Messrs. Venn and Gibbons. Best collection of Apples, eight dishes and eight entries, prizes given by Messrs. Laing and other friends.—First, Mr. Venn. Best collections of Pears, four dishes (six entries).—Prizes given by Messrs. Cheal & Son. First, Mr. Kemp. Two best bunches of Grapes (three entries).—First, Mr. Hodges. Best collection of vegetables, prizes given by Messrs. Sutton & Sons, Reading (seven entries).—First, Mr. T. Venn.

LINCOLN.—NOVEMBER 17TH AND 18TH.

The third Exhibition of the Lincoln Chrysanthemum Society opened on Tuesday last in the spacious Corn Exchange of the ancient city. The Show, though decidedly attractive, was not considered quite equal in merit to that of last year. Early frosts appear to have done much injury to the buds, for two of the leading local exhibitors, Messrs. Wipf and Caulling, left the field open to other competitors. The bulk of the prizes for cut blooms was secured by Mr. Bugg, gardener to W. Ashley, Esq., and Mr. Mitchell, gardener to W. J. Waverer, Esq. In the open class for forty-eight blooms there was only one collection, and for this Mr. Mitchell was awarded the second prize of £5. His Japanese blooms were of fair merit, but the incurved were very small. He was quite satisfied with the decision. In the class for twenty-four blooms Mr. Bugg was well ahead, followed by Mr. Mitchell, and they had the same positions in five other classes, while in three more—twelve Japanese, Anemone Japanese, and Pompons—Mr. Mitchell took the lead. The best Japanese bloom in the Show was Fabian

de Mediana, in Mr. Mitchell's stand; the best incurved flower, Empress of India, staged by T. C. Bourne, Esq. Groups of Chrysanthemums were gay, but as a rule defective in quality of flowers and in the finish of the front row. Groups of mixed plants were much better; indeed, very good indeed, especially those of Mr. Mitchell and Mr. Foster, gardener to H. Greenham, Esq., who had the first and second prizes, Messrs. Harding and Bugg following. Mr. Pennell arranged a handsome group, not for competition, which was highly commended by the Judges, and Mr. Illman was commended for meritorious assortment. There was a great and good display of Apples and Pears, and good Grapes were staged by Mr. Allis, gardener to Major Shuttleworth, Old Warden, Biggleswade, who had the chief prizes. The Show was well managed by Dr. George Lowe and his assistants, and the public attendance promised to be great.

READING.—NOVEMBER 13TH.

A LARGE and very meritorious Show was held in the Town Hall on the date named. Groups were remarkably good, the prizes going to Mr. Baskett, gardener to W. J. Palmer, Esq., and Mr. Parham, gardener to H. J. Simonds, Esq. Specimen plants were not of special noticeable quality. Cut blooms were very fine. In the class for eighteen incurved the prizes went to Mr. Neville, gardener to F. W. Flight, Esq., Winchester; Mr. Wildsmith, Heckfield; and Mr. Pope, gardener to the Earl of Carnarvon. There was great competition also in the Japanese class for twelve blooms, no less than nineteen stands being placed in position. After much deliberation the prizes were awarded to Mr. Holdaway, gardener to Major May, Mr. Nevill, and Messrs. Wildsmith and Baskett, the latter being placed equal third, extra prizes being further awarded to Messrs. Strong and Pope. Anemones were good, Messrs. Wildsmith, Kendall, and Elliott being the prizewinners in the order named. Fruit was well shown indeed, the prizes falling mainly to Mr. Turton, gardener to J. Hargreaves, Esq., and Mr. Perkins, gardener to W. H. Smith, Esq. The attendance of visitors was very large, and the Exhibition promised to be financially successful.

HUDDERSFIELD.

THE second annual Show was held in the Town Hall on the 13th and 14th inst. With the liberal prize list of over £35 devoted to four classes of cut blooms, open to all, it is much to be regretted that so few exhibitors responded. The absence also of exhibitors not for competition was felt and regretted; nevertheless, as a whole the Show was an attractive one. The improvement that has taken place was most noticeable in the plants exhibited; indeed, the first-prize group of Chrysanthemums in half a circle of 54 square feet, shown by Mr. F. Hatch, gardener to Alderman J. F. Brigg, was made of really splendid examples of cultural skill. The table plants and cut blooms of Chrysanthemums exhibited by Mr. William Daniels, gardener to Mrs. Cooke, Hall Croft, Mirfield, were of a high order of merit, justly gaining first prizes in their several classes. In the class of six table plants some of the exhibitors had entirely spoiled their chance of success by, as it were, varnishing the foliage over with what appeared to be some preparation of glycerine; the Judges very properly discountenanced such malpractices. In the open class for best bouquet much condemnation was expressed of the Judges' award. It would be well if more attention was given to this matter.

The principal prizes were secured by the following exhibitors:—Mr. A. R. Cox, gardener to W. H. Watts, Esq., Liverpool; Mr. F. Stoker, gardener to Mrs. Charles Crosland, Crosland Moor; Mr. Mark Chambers, gardener to J. Vickerman, Esq., J.P., Taylor Hill; and Mr. F. Hatch, gardener to Alderman J. F. Brigg, J.P.

EARLY-FLOWERING CHRYSANTHEMUMS.

ANOTHER season of the early-flowering Chrysanthemums has gone. Upon the whole it has been a good season in this part of the country, for though too hot and dry during the summer, where the plants have had water enough the sun has well ripened the wood and perfected them.

Perhaps it will be well for me first to deal with the Show at the Crystal Palace, Sydenham. This time there were four competitors—viz., Mr. N. Davis of the Lilford Road Nurseries, Camberwell, S.E.; Mr. H. James of Castle Nursery, Lower Norwood; Mr. A. Luff, gardener to R. R. Hetherset, Esq., Leigham Court Road, Streatham; and myself. It must be understood that the schedule offered prizes of £4, £3, and £2 for a collection of early-flowering "Chrysanthemum indicum" (to be sufficiently in flower for decorative purposes), not less than six varieties, three plants of each, and grown in pots not exceeding 8 inches—that is, measured across the top inside the rim. These are what are called 24's, and are really too small to do full justice to the plants; still a rule is a law, and ought to be complied with; but many of Mr. Luff's pots were too small, and some of Mr. James's were too large. The latter showed a very fine group of Madame Desgrange, but his other sorts were inferior plants in comparison with Mr. Davis's and my own. If eighteen plants were only shown that would comply with the regulation, but Mr. Davis last year not only complied but did much more, and he obtained first prize; and as I saw that there was no objection raised to his doing so, and as I only on that occasion had second prize, this year I not only complied with the rule, sending eighteen plants to regulation, but sent nearly fifty. Of course from last year's experience I thought that the authorities of the Palace not only were willing to give the prizes, but were desirous to make a good show, and if we had no pot larger than a 24 we thought we were right, and so far we were, for I took the first prize; but there was much dispute about the others, although Mr. James had second and Mr. Davis third. I do not know how Mr. Davis failed, but chiefly, I think, because the plants were not quite early enough. He was, however, I think the first person to publicly exhibit plants of the yellow sport of Madame Desgrange. It is very beautiful in its new colour, and deeper in the open air than under glass. The winning varieties on this occasion were Madame Desgrange, Mrs. Cullingford, Madame Jolivart, Lyon, Early Late Flora, and Nanum. We were also able to put up for show the new varieties La Bien Aimée, Surprise,

Salter's Early Blush, Mons. Dufoy, Fiberta, Bronze Early Cassy, White Crouts, Frederick Marronet, Yellow Zenobie, and Petite Marie. To these will probably be added next season at least two sorts—viz., Blushing Bride and Piercy's Seedling.

One of the most important incidents this season has been the general appearance of the yellow Madame Desgrange for yellow; it is not golden as some say. I have grown plants from two distinct sports of it this season, and cannot see the least difference in them; they are exactly the same shade—bright pale yellow. I know of two more sports, and shall try to see them if possible. No doubt that we shall have a deeper sport in time, one that we can truly call golden. Mrs. Rundle produced the sport George Glenney before Mrs. Dixon, so we may feel almost sure that a deeper coloured Madame Desgrange will come, especially as the yellow is already so widely distributed and largely grown.

Salter's Early Blush upon a second season's experience proves all I thought of it last season, and is certainly the best of its colour.

Fiberta, too, has in no way fallen from its place as the very finest pale bright yellow early Pompon upon a second season's experience. It was said last season that this was sometimes labelled incorrectly Jardin des Plantes, but I do not think it was. The one called Jardin des Plantes was wrongly so named, first, I think, at Parker's nursery at Tooting, but that was the poor old thing Madame Domage, or a yellow Madame Dufoy, for the white Madame Dufoy was there called White Jardin des Plantes. These names were and are quite wrong, for neither of them is like the proper late sort, Jardin des Plantes.

Early Late Flora.—It is perhaps well to say a little more about this excellent and important yellow Pompon. It came here with the title Late Flora, which was so absurd that I gave it the prefix of Early, because it was difficult to preserve its identity any other way. Now somebody has called it simply Flora, and as I can hear of no other Flora there can be no objection to the simplification. It is a truly excellent plant; the market men are beginning to think so, and it has made its appearance in the shops in and about London. Mrs. Cullingford, too, is growing, still growing, in public estimation, as is also White St. Crout's, but Petite Marie is generally found to be a very weak plant, somewhat difficult to keep.

The new early sorts of this season are very various both in colour, merit and earliness. The first in importance is Blushing Bride. This variety came from the continent late in the season much damaged by packing, and among wrongly named plants, by reason of which we do not know its proper name, but as we cannot work without one Mr. Davis of Camberwell and myself have given it the above title. Doubtless in due time we shall discover its original designation. I say all this that no one may think that there is any desire, either on the part of Mr. Davis or myself, to rename plants unless it is unavoidable. Blushing Bride is of real value to be put beside Lyon, Flora, and Madame Desgrange, unless in future we should find some fault in it we have failed to discover this season. I always feel it necessary to make some reservation in speaking from the first season's experience, though I have little doubt that this will show better next season. As to its earliness, it had just come into bloom on the 15th of September, which was on the second growth, the first having come very imperfectly through its injuries in transit. At that time it was 2 feet 4 inches high, of stiff, stout habit, with the flowers held well apart on separate stalks, so that each flower had room to come out without any trouble to take off buds, and this is necessary in garden plants, or where they are grown in large quantities for decoration or cutting. The flowers are 2½ inches across, of a bright transparent blush or pinkish colour, very much like old Aureole, but the form of the flower is much better than that, being very full. A flower counted had 394 petals, each one curving in, of a long spoon-bowl shape. I regard it as one of the finest Pompons ever seen in England, either early or late. Of course it will be scarce the first season, there only being two plants in this country as far as I know, and it is very probable I should have heard had there been more.

PIERCY'S SEEDLING.—This is the first good seedling I have raised, and up to this season I think the useless varieties in that line have been about 500 from seed from various sources and indifferent years, so no one need be discouraged at their produce from seed being bad. The seed was sown in heat on March 1st, the leaves appeared in six days, and the plant was in bloom on September 11th. This fully disposes of the tales I heard years back that seedlings did not bloom till the second year, though some I have raised seemed as if they would never bloom, and certainly did not so the first season. Out of 100 seedlings no two had foliage and habit alike. A The plant under consideration grew 21 inches high, bushy in habit, and very floriferous, the top of the plant being a solid mass of flowers all good, and showing no eye. The flowers are from 2 to 2½ inches across, slightly reflexed when full out, the petals being short, stout, and thick. The colour is red orange to yellow. It is a real good open air plant.

LA BIEN-AIMÉE.—This is a pretty little Pompon growing 17 inches high. It came into bloom June 22nd from a top cutting inserted March 13th. It resembles Model of Perfection in the form of the flower being very full and a little reflexed, measuring 1½ inch across, and being a reddish violet in colour. It makes a pretty small pot plant.

ROI DES PRÉCOCES (King of the Earlies).—I do not consider this the king of the earlies by any means. It is a crimson Japanese of very bright colour, but not quite pure. It came into bloom at the end of September from cuttings inserted at the beginning of May, so it is quick in coming to perfection. It was then 2 feet 6 inches high. The flowers are 3½ inches across, the petals narrow and reflexed. It is valuable on

account of crimsons being scarce, but would be much better for disbud-ding. It is of stout habit.

SURPRISE.—This is a Pompon much like the late variety called Laciniata superba. It has a very stout flower with a short thick petal, giving the flower a button-like form of a dull pink colour 1¼ to 1½ inch across. It is a quick robust grower, though rather slender in habit, about 32 inches high. A top cutting put in March 13th bloomed by the 29th of July. The foliage is very dark.

PETIT MIGNON.—There must be some mistake about this. It was sent here from France this spring as quite new, but when it came into bloom it proved to be one we had last season with the name Mons. Dufoy. It came into flower at the end of September, and grows about 3 feet high. The flowers are about 2 inches across, composed of short thick petals, forming almost a ball of a lilac colour.

BOUQUET ESTIVAL.—This is a Japanese; grows about 32 inches high, and has flowers of a ragged structure 3 inches across, which come in clusters on thin wood, so that it wants care to keep it up. It would be better for some of the buds being taken off, as it is a profuse bloomer. The colour of the flowers is a deep lilac, but some branches are much darker than the others, of a bluish crimson tint. It came into flower September 15th from March-struck cutting.

JEANNE COUSINIE flowered September 18th. Its height is 15 inches, and the blooms are 1½ inch across; red violet in colour. L'Immortelle and Madame Prilleux both turned out Old Illustration syn. Marie Longarre.

TOREADOR.—This is a red, and a valuable plant because reds are scarce. It resembles Frederick Pélé in habit, but is, I think, rather better as well as brighter red. Its flower is 2 inches across, and the plant grows about 2 feet high, with rather slender habit and spare foliage. It bloomed September 6th.

MAD. BLANCH PERTUZES.—A very nice dwarf plant, growing 1 foot to 18 inches high, bearing a white flower, about 2 inches across, of exquisite form, the petals being short and thick.

MIGNON.—I did not receive this plant till late in the season, and so may have to qualify the character after a full season's culture. As it appears to me this time it closely resembles Fiberta, only that it does not grow more than half the height of that, being only 18 inches high, having the flowers not so large, only 1½ inch across, very bright yellow indeed. It bloomed September 12th. If it should grow no higher next season it will be one of the best small pot plants ever imported. It is a most profuse bloomer, and, I think, of stouter habit and better to propagate than Fiberta.

Bronze Early Cassy has now sported this colour from the yellow sport of the pink one in all my plants, and only becomes yellow when it is fading. Higham.—This is a blush sport of St. Mary, and resembles it in every way except colour. White and yellow bedders are both poor varieties.

I have to thank Mr. F. W. Burbidge, Curator of Trinity College Botanical Gardens, Dublin, and author of "The Chrysanthemum," for his kind assistance and the introduction of these varieties into Ireland; and also Mr. William Dick, garden superintendent of Phoenix Park, Dublin, for his introduction of them there; also I must specially thank Mr. John Thorpe, of the firm of nurserymen Messrs. Hallock, Son, & Thorpe, Queen's, New York, U.S.A.; Mr. T. S. Ware of Hale Farm Nurseries, Tottenham, London, N.; Messrs. Laing & Co., nurserymen, of Stanstead Road, Forest Hill, S.E.; Mr. Watson of Whittington Road, Bowes Park, London, N., and his son, Walter Watson, of The Grange, Walthamstow, Essex; and last, but not least, for the kind, friendly, and very efficient aid of Mr. N. Davis of Lilford Road, Camberwell, London, S.E.—W. PIERCY, 89, West Road, Forest Hill, London, S.E.

ESCALLONIAS.

THESE are generally regarded as half-hardy evergreens, suitable only for planting to cover walls in southern aspects or sheltered positions, and even then require protection in winter. This, I am fully aware, is the experience of many, and it is without doubt their true character when planted inland, more especially in the northern parts of the country. Those who have only seen these plants in the positions indicated where they are struggling hard to exist and furnish the space allotted to them—that is, growing strongly and vigorously in summer, only to be cut down in winter, can form no idea of their real beauty. I have seen these plants cut down annually to the ground in only ordinary winters, but they do not die, but spring freely and vigorously again from the base, and grow rapidly the following summer. Those who have planted and been disappointed would condemn them even for furnishing walls, and would doubtless advise, as many have done, the space they occupy to be filled with other plants that would prove more ornamental and useful.

In spite of these drawbacks, however, Escallonias are amongst our most effective flowering shrubs in positions where they prove hardy and grow luxuriantly. I do not believe these are adapted for inland planting, for they are really seaside-loving plants. They are perfectly hardy by the coast, and thrive amazingly on the shore fully exposed to the sea, and flower profusely. I have seen them both in Wales and in the Isle of Man fully exposed where many trees were stunted and unsightly. They are most beautiful on walls, where they do well. E. sanguinea, with its less robust habit, is most suitable for this purpose, but both this and E. macrantha are much more conspicuous when planted singly and allowed

to develop into natural bushes. They are admirably adapted for this purpose, and when good bushes are seen in flower they are not easily forgotten. I would strongly recommend them to be planted largely in all gardens and grounds by the sea, both in shrubby borders and as single specimens on lawns. They will grow where some of our hardiest Hollies suffer dreadfully and present a very wretched appearance as the result of the cutting winds of the sea, but Escallonia appear rather to enjoy these winds than otherwise. *E. macrantha*, with its large, bright, dark green shining foliage, when well developed will compare most favourably as single specimens with Hollies.

These plants will bear hard pruning; in fact, I have seen them annually cut in closely with the shears. In certain positions they look very well when subject to this treatment and the surroundings harmonise with such formal specimens. I do not admire these formally trained specimens when they can be kept shapely and at the same time present a natural and beautiful appearance by a judicious use of the knife. Even when trained to develop into symmetrical specimens they should be allowed a little freedom of growth, and when pruned their outline should present some little irregularity, which adds materially to their beauty as naturally grown specimens. The best time to subject these plants to whatever pruning they require is after they have flowered, and even then close cutting back is not needed. By regulating and pruning what is necessary after flowering, the plants are ready in spring to make again a strong vigorous growth. These plants flower on the young wood, and should not be cut during the growing season further than may be necessary to check too luxuriant growth.

Escallonia are propagated by means of cuttings, which root readily and quickly if the end of the young growths are selected when half ripened. They can, however, be rooted at almost any season of the year, but late summer or early autumn is preferable; in fact, I have inserted numbers of them after that date and with very marked success. The portion of shoot selected for the cuttings should be about 2 inches in length, and cut close to a joint with a sharp knife, the lower leaves being removed for about half their length. If inserted during late summer or early autumn the cuttings should be placed thickly together in sandy soil, and covered with handlights or small glass frames situated behind a wall or hedge. Give a good watering, and keep the handlights close until the cuttings have formed roots, when they should be gradually hardened by admitting air, and then placed singly in 3-inch pots. If inserted later in the season we prefer placing them in sandy soil in 8-inch pots, then have bellglasses over them, and stand them in a shady part of any house kept moderately close where the night temperature will range about 50° to 55°. They are not particular, for they will root more quickly and equally as well if they can be placed in a close frame where a bottom heat of about 75° can be given; but I prefer the first method if only the cuttings are inserted early enough. They are not so liable to become checked when rooted under cool conditions as is the case when heat is employed. They are not so long forming roots as many plants, and whichever system is adopted they should be placed in the pots named and wintered in them.

If rooted early they will be established before winter and must have the protection of a cold frame. As soon as the small pots are full of roots they should be placed into others 2 and 3 inches larger, and then when the weather is favourable they can be plunged outside, covering the pots to save labour in watering. These will be by the following autumn good plants about 1 foot high, and can be planted out early in favourable localities to become well established before winter. In uncertain localities planting had much better be deferred until the spring, and the plants protected in a cold frame.

In nurseries where these plants are raised for sale they are grown in the size pots referred to and plunged out in them during the summer, so that they can with safety be obtained and planted at any season of the year. During winter they keep them in good condition by lifting the pots and protecting them in cold frames.

There are several varieties of Escallonia, but I am only thoroughly acquainted with the two mentioned, the flowers of them both being bright red. There is a white-flowered variety, I believe, named *E. montevidensis*, but I have never seen it in flower, and shall be glad to learn from those acquainted with it if it is as hardy as *E. macrantha*, and equally as beautiful and free-flowering.—B.

TORENIA ASIATICA.

THIS lovely plant when first introduced was supposed to require stove treatment, but fortunately, although the plant needs a warm atmosphere in the winter season, it will during the summer months bear a considerable reduction of temperature below that originally believed to be necessary for its healthy condition, growing luxuriantly in the greenhouse or the window of an ordinary apartment, and under certain conditions in the open air.

As its specific name implies, it is a native of Asia, "growing throughout Bengal, in Amboyna, Ceylon, Merqui, Chittagong, Sylhet, on the Madras Peninsula, and it is also widely diffused in alpine regions." By some writers it is said to be an annual plant; but as it may certainly be preserved, in a proper temperature, one or two winters at least, this designation can hardly be correct, though it may be raised from seeds and treated as an annual.

Its pale green serrated foliage is not devoid of interest, but its chief

attraction resides in its charming violet flowers, which are produced profusely through the summer months up to a very late period. They are of a peculiar rich velvety tint, especially in the two lateral lobes of the corolla, where it is most intense. After the flower has been some days expanded it loses a little of its depth, particularly if exposed to strong sunshine.

It is of the easiest possible propagation, cuttings 2 or 3 inches long, planted under a glass in a pot of light moist soil, and placed upon a warm window, rooting with even greater readiness than the well known *Cuphea platycentra*, which is one of the quickest-rooting plants with which we are acquainted. The plant affects a vegetable soil, and will do well in a mixture of peat or leaf mould and sandy loam, with well-drained pots of moderate size.

When grown as a window plant it is best trained upon a flat trellis, which from its growth it will speedily cover, and to induce its lateral extension the extremity of the shoots should be frequently pinched off, or the pot may be suspended, and the branches allowed to trail down-

Fig. 70.—*Torenia asiatica*.

wards, in which position the elegant habit of the plant, combined with its lovely blossoms, renders it a highly interesting object.

The genus *Torenia* commemorates the name of Olof Toren, a Swedish botanist of some eminence. About six other species have been introduced, one of which, *T. scabra*, a plant well known to gardeners, may be cultivated as a half-hardy annual. *T. concolor*, introduced a year or two before *asiatica*, is an interesting species, the flowers of which are entirely of a deep bluish purple, and, coming from Hong Kong, it is rather more hardy than *Torenia asiatica*.—W. T.

HARDY FRUIT GARDEN.

CORDONS.—Special attention should be given to the value and utility of cordons for all gardens great and small, and preference be given to them for many purposes. First of all we should turn to account every foot of wall space, especially for Pears, a wall covered with cordon Pear trees being now recognised as one of the most useful and attractive features of a fruit garden. We altogether prefer single cordons, planting them 18 inches apart, and training them either vertically, diagonally, or horizontally, as may be necessary; the first method being most suitable for high buildings, the second for walls and fences, the third for the base of lofty walls and buildings and for the margins of paths, in which last position we have seen them laden with fruit. Another method admirably combining the ornamental and useful is to plant them along each

side of a broad path and train them to an arch overhead. Apples, Pears, Plums, and Cherries may all be so used, and on walls and buildings we have cordons of Peaches, Nectarines, and Apricots that in all favourable seasons are laden with fruit. The special advantages of cordons are early and persistent fruitfulness, the ease with which the blossoms may be sheltered, the small amount of space required—given 18 inches width from wall or fence and you have ample space for a cordon. Pray bear this in mind when you see spare nooks and angles of buildings which may be turned to account and afford you much fine fruit, for remember a cordon is no mere toy, but a valuable fruit tree. Some of the finest fruits at the recent Pear Congress were from cordons, and we can say that for several years our wall of cordon Pears has never failed us, a fair crop of fruit being always forthcoming when pyramids, palmette verriers, and standards all failed us. To owners of small gardens cordons are a great boon, enabling them to have fruit in much greater variety, in longer succession, and greater excellence than was possible from other trees. In connection with cordons we may call attention to the value of a wall for the development of flavour in fruit. Repeatedly have we had fruit of the same sort worthless from pyramids yet excellent from wall trees. Wall fruit, once a luxury only to be had by owners of walled gardens, is now obtained from cordons on a lodge or dwelling-house. A lofty chimney is one of our very best supports for vertical cordons. A border 6 feet wide and 2 feet deep of sound rich loam is all that is required for them, and it can easily be enriched before the trees show signs of exhaustion by the application of surface-dressings of manure; or, better still, by the regular use of liquid manure every summer while the fruit is swelling.

FRUIT FORCING.

Peaches and Nectarines.—*Earliest-forced Trees.*—The house will by this time have been cleansed, the trees dressed, and the shoots tied in. The lights, if not already replaced, must at once be seen to, and assuming that ripe fruit is wanted before the end of May it will be necessary to close the house at once, as it is advisable not to apply fire heat for at least a fortnight after closing. Old trees that have been judiciously managed and forced for a number of years are more easily excited than young ones, but in either case it is well to exercise patience through the early stages, and on this account an early start is of great importance. When the weather is so cold as to necessitate fire heat to raise the day temperature to 50°, it should be so applied as to allow the pipes to become cool before nightfall. The lights having been off the house, the inside borders will be sufficiently moist, but they should be examined and watered with tepid water if necessary until all the soil is moistened down to the drainage. A ridge of fermenting material placed on the inside borders composed of Oak or Beech leaves and stable manure, will answer the twofold purpose of saving fire heat and giving off genial atmospheric moisture. The manure and leaves should be well fermented before being taken into the house, and if a portion of it is turned every day very little fire heat will be needed for the first three weeks. Ventilate a little every day to sweeten the atmosphere, syringing the trees, walls, and paths with tepid water about 9 A.M. and 2 P.M., when the weather is seasonably fine, but when there is a danger of the buds not getting dry before night the second syringing must be given earlier in the day or omitted. The temperature should range from 40° to 45° at night, and 45° to 55° by day, with a few degrees more from sun heat, or 5° to 10° until the buds are starting, when a slight increase on fine days may be allowed. Where the roots have the run of outside borders the latter should be well protected with some material for throwing off heavy rains and snow, and keeping the surface roots in action, as nothing can be gained by the mistaken practice of starving the roots while the branches are in a state of activity.

Succession Houses.—Take advantage of unfavourable weather for outdoor operations to have all pruning and cleansing operations brought to a close, seeing that the roots of trees under fixed roofs do not suffer from want of water, otherwise the blossom buds will fall when the time arrives for forcing, a season being thereby lost, and root-pruning will in all probability have to be resorted to to check the undue vigour which loss of crop on otherwise healthy trees entails. If the trees have been infested with red spider or scale they should be washed twice with a solution of softsoap, 4 ozs. to the gallon of tepid water, and afterwards dressed with an approved insecticide, that will not leave a thick deposit as some compositions do, closing the pores of the wood, and often disfiguring the fruit when it is washed off by the syringe. When finished allow a free circulation of air through the houses until the time arrives for starting the trees, and where practicable they should be kept clear of plants of all kinds subject to insects, or which are liable to be injured by a few degrees of frost, as it is important the trees have perfect rest, and be not excited by heat foreign to their requirements. Young trees that have become too strong may be improved by lifting and relaying the roots in new loam free from animal manure, training them afterwards upon the extension principle, and allow them to grow into a fruitful state. Old trees that lack vigour may be strengthened by the removal of the surface soil, and watering thoroughly with liquid manure not too strong, prior to giving a dressing of new compost of rich turfy loam—preferably of a calcareous nature; if not, add a tenth of old mortar rubbish, a twentieth of burnt refuse, and a fortieth of bone dust thoroughly incorporated. Surface-rooting should be encouraged by rich surface dressings of manure during growth.

Pines.—It is of the greatest importance at this time of year to have the plants so placed as to obtain all the light possible, deriving all the benefit possible of every ray of sunshine, therefore keep the glass clean, and let the plants be placed as near to it as can be done consistently with

safety. Fermenting beds settle through decomposition, and newly made ones, unless well trodden, subside very rapidly; in either case the necessary attention should be given to raising the plants into a position so as to afford the benefits indicated. It is a good practice to assort the plants according to their respective needs before the winter, and to give the fruiting plants the best places for swelling their fruit properly at a time when natural means do not afford much help. Fruiting plants under any conditions should have a night temperature of 65°, and 70° to 75° by day, with an advance of 10° from sun heat. Successions need only have 60° at night and 65° by day, with 5° to 10° rise from sun heat. Other stock, which are not prepared or intended to make much growth, need only be kept at 60° at night, falling 5° on cold nights, with 60° to 65° in the daytime. Fruiting plants will need a genial condition of the atmosphere, atmospheric moisture being necessary at all times, therefore sprinkling must be seen to regularly, and syringing in a light house will be needed at least two or three times a week. Successional plants and suckers will only need an occasional dash from the syringe, but anything like an acrid condition of the atmosphere should be avoided, as it stunts and cripples the growth irretrievably. As Oak and Beech leaves are now available, and being the best and most durable, new beds should be made as necessary. It is a good plan to free the pits of all the plants, make the beds, and not put in the plants again until they are in a proper condition, as more injury arises from the plants being shifted about, and placing on cold, or its opposite, very hot beds, than is considered creditable. The less check given these, indeed any plants, the better; and although Pines may not show it immediately, as do some softer-textured plants, yet they will show it, and at a time when they are wanted to make growth, which they are unable to do from the results of the check given some time previously.

PLANT HOUSES.

Cypripediums.—The old *C. insigne* should be placed in a temperature of 50° to 55° to unfold its flowers. It will open them very well under cool conditions, but a little heat draws up the flower stems well above the foliage, which gives to the plants a much more effective appearance for decorative purposes. When the flowers are expanding the plants should be removed to the conservatory or any similar position while in flower, and they will be found to last in good condition for nearly three months. The plants intended to succeed these should be retarded by keeping them as cool as possible, or they will come forward too early. At this season of the year they will bear cool treatment without the slightest injury. The useful *C. venustum*, with its dark ornamental foliage, is now showing its flowers—that is, those that have been grown in heat, while those grown under cooler conditions are not yet showing. This variety forms a good succession to the preceding, and can be retarded or brought forward according to requirements or circumstances. *C. Spicerianum* is a gem amongst autumn and winter-flowering Lady's Slippers, and it appears to stand moderately cool treatment after growth is completed, or while in flower, without injury; in fact the lower temperature of the conservatory is beneficial to it while in flower, and growth afterwards is more robust. *C. Sedeni* is very beautiful, and its rose-coloured slippers render it very telling and effective at this season of the year, for the colour is distinct from any others. The flowers being produced in succession for several months renders it a very useful variety. *Cypripediums*, whether under cool or warm treatment, should not be allowed to suffer by an insufficient supply of water at their roots, for they have no pseudo-bulbs from which they can draw support. Less water will be needed than during the growing season, but the compost about their roots should never be allowed to become really dry. At this period of the year watering over the foliage should not be practised, or the foliage of some species is liable to become spotted. The atmosphere must not be kept too moist, or the same results are liable to follow. The structure in which the warm varieties are grown should be kept about 60° at night, with a rise of 5° by day, while those under cool treatment should not be subjected to a lower temperature than 45°. Those that it is anxious to retard may be kept 5° lower for a time without any injury to them, providing the atmosphere is not too moist.

Laelias.—Some of these, such as *L. purpurata* and others of that style of growth, must be kept in the same structure as Cattleyas. The plants should be arranged at the coolest portion of the house, according to the condition of their growth. The treatment for these during the resting period is similar to that advised for Cattleyas. *L. anceps* and its varieties will be in various stages of development according to the treatment, as regards heat, that they have been given during the season of growth. Those that have been grown warm will have their flower spikes well advanced, and may be kept in a temperature of 60° until the flowers expand, and then be removed to a cooler and drier atmosphere while in bloom, a temperature of 50° to 55° being very suitable for them, and if kept dry they will rest well under these conditions after flowering. All that have been growing in an intermediate temperature for the purpose of giving a succession will, although growth to all appearance has been completed, now be making roots freely. These must be regularly supplied with water as they need it until root extension ceases, for fine large well-coloured flowers and plump pseudo-bulbs cannot be expected if those in this condition are sent prematurely to rest by withholding water. Smaller-growing kinds on blocks and in small pans that are suspended at the warmest end of the cool house, should be watered until growth is thoroughly completed; then water should be gradually withheld and the plants kept as dry as can be done without allowing the pseudo-bulbs to shrivel.

Odontoglossums.—Such species as *O. Roezlii*, *O. vexillarium*, *O. cirrhosum*, *O. citrosimum*, and others, require a little more heat during the

winter than such species as *O. Alexandræ*, *O. Pescatorei*, *O. triumphans*, and others, and should now be removed from the coolest house. We place our plants with the *Cattleyas* for the want of a better place. They will do well and pass the winter safely in any structure where a temperature of 50° to 55° at night can be maintained. These varieties should be watered at their roots as they need it. If kept as dry during the winter season as is necessary for many Orchids they will be seriously injured, if not entirely ruined. These plants should never suffer, not even during the winter, by an insufficient supply of water at their roots. The temperature of the coolest house should range from 45° to 50° at night, according to the weather. The lowest figures given should only be allowed in the morning during cold or severe weather. Nothing is gained by starving these plants during winter, but, on the contrary, the following season may be required to recruit them.

THE BEE-KEEPER.

THE GENERAL MANAGEMENT OF BEES.

A RETROSPECT.

It is now a long time since this Journal commenced. It is, perhaps, the first journal that devoted a portion of its pages to apiculture, and allowed free discussion on all relating to it, which was continued by many of the most eminent writers and practical apiculturists. Weekly its pages had something new and interesting, which was eagerly read by most of the bee-keepers in the kingdom. To the contributors to the pages of this Journal at that time are we indebted for the advanced state of apiculture at the present. "A Scotch Bee-keeper" thirty years ago, or thereabout, explained the Stewarton system of insensible upward ventilation. Mr. A. Neighbour, of Messrs. G. Neighbour & Son, spared neither time nor expense in obtaining any and every thing that was likely to advance apiculture. To that gentleman alone are we indebted for the introduction of comb foundation and foreign appliances, as well as the different races of bees, and in which Mr. T. W. Woodbury joined. He also exerted himself to construct a hive for the cottager that would combine utility and cheapness, but, after a fair trial, found that to possess a really useful and lasting hive, a certain sum must be expended if success was to be looked for. He wisely abandoned the idea, giving his opinions and experience instead, so that the cottager might benefit thereby. It is rather a difficult task to direct others to attain the simplest yet most effective and cheapest article. For example, when I recommended angle or T iron for use with the "best hive in creation," it is not what I use, but I recommended it only as an example of what it should be, and that no mistake could be made. Common hooping is all that is necessary, that placed between two rails and fastened with screw nails is more easily managed and cheaper. The introduction of comb foundation by Mr. A. Neighbour, as well as the foreign varieties of bees, also completely revolutionised bee-keeping; and there have been various other advances and improvements which have been duly recorded in these pages.

USEFUL HINTS.

Winter is upon us, but has brought mild weather, the temperature being as high as 57°, therefore our bees have at the last moment had an airing without which it would have probably proved fatal to many bees, as breeding was carried on briskly during October, wherever there were young queens. Where it had ceased the bees had been already confined for six weeks. One hive having a year-old Syrian queen had ceased labour and breeding during that time, but with the milder weather they have started breeding afresh, and are as busy collecting water and what pollen they can get as if it was May. This is rather early should the winter be severe. November-bred bees are not so injurious or risky in a hive as October-bred ones; still it is inadvisable to have bees breeding in November. To stop it, the ventilator beneath should be drawn, and perhaps some of the covering, but the present being an exceptional season, it may be as well to let them alone, only the hint may be taken.

A very important thing at this season is neither to alter the site nor appearance of the hive unless the distance be several miles, then bring them back after two months. I have a hive now of which I had occasion to shift the entrance from one side only to the other about six weeks since; though that time has elapsed since, on the bees airing themselves during the mild weather, every one of them, on re-entering the hive, went to the side they had been accustomed to before it was altered. Had the hive been shifted a few yards many of the bees would have been lost; for, remember, though the temperature is high, the air is damp, and whatever they rest upon soon draws the heat from their bodies. If the weather keep mild, and the bees on the wing, attend to keeping the floors clean and dry.

Little more than a month will bring us to the time bees begin breeding, gradually extending as the season advances, and consequently nearer the outer edge of the cluster, but seldom to the extreme unless in small hives and during warm weather. If the hive is of sufficient size, and well provisioned, they require little or no attention until swarming is expected or supers are wanted. In fact, bees, where properly managed, only require close attention from May till September. However, the majority of hives in use are so small that it is impossible to bring bees to the swarming point without feeding, thus incurring both extra labour and expense, with a much less yield of honey.

The subject of brood-spreading has been so well threshed out of late that, but for one or two things, it might be allowed to rest. The late Mr. Pettigrew, though he differed from us in opinion on some things, was right in his argument to have large hives with plenty of bees. These are the two essentials towards successful bee-keeping, and the proper way to spread brood, and when the British Bee-keepers' Association took it upon themselves to fix a standard hive of about half the size, it ought to be run counter to common sense and sensible and profitable bee-keeping. I wonder if it ever occurred to the advocates of brood-spreading to think about what they were teaching. In the first place, advising the spreading of brood at a time the hive ought to be full to overflowing. A better plan would have been to advise that brood-spreading was neither necessary nor possible. Otherwise it points directly to previous bad management. How often has the *British Bee Journal* told us of the loss of three thousand eggs daily by some neglect or other in not giving sufficient breeding space. It is very well if other things had been in keeping, but we find what they recommend stultifies their argument. Hives half the size they should be will be filled with eggs in eight or nine days, and when brood-spreading takes place, according to the number of frames already tenanted, as recommended, and to insure the three thousand eggs daily the whole operation of brood-spreading would have to be performed in about a week, and this with the weakest hive recommended. Can anything be more absurd?

Feeding does good to bees approaching want, but none whatever to well-provisioned hives. The evils of feeding are many. In an apiary where feeding is never resorted to robbing seldom occurs; the bees never being enticed out are safe from cold, the hive is kept stronger and progresses more steadily and quickly than those fed. Feeding weak hives draws the bees from the stronger ones to rob. Feeding strong hives gives bees an appetite for more, annoying every hive in the neighbourhood, losing themselves in great numbers by fighting or cold. Then the damp engendered in fed hives is so prejudicial to the welfare of bees that it should never be resorted to unless when it cannot be avoided.

Feeding swarms when honey is scarce is a great advantage, and a swarm so attended to will give a large return of honey when swarms on an equal footing at first, but neglected, will give nothing. The evils of feeding are that some of the sugar may get amongst the honey, and the sugar-fed combs are more brittle and more liable to decay than combs made in the natural way from honey.—A LANARKSHIRE BEE-KEEPER.

A YEAR'S RECORD.

THE falling leaves as they fall from the parent bough, and the dying verdure of the fields and woodland glades, give warning that a time of rest is near, and that Nature is quietly passing to her annual repose. The solitary bee as it leaves its hive and returns with but a slender little load gives evidence that even these, the busiest of insect tribes, finding the season over in which they are able to gain an increase to their store, are carefully husbanding their strength in order that another spring may find them the more ready to take advantage of its flowers. Not so, however, the bee-master, who is indeed at all times busy either scheming how to assist his insect labourers in their toil or planning some new device or form in which to take the surplus he hopes to obtain in the future season.

This is the time when a most fitting opportunity is presented of calculating the result of the season now gone by before looking far into the time which is to come. If—and that it is so there can be little doubt—a good nett profit is the aim of the bee-master, now is the time to strike the balance of the year, to correct or to examine causes of failure in the past, and to lay a sound foundation for the future. To pass on then let me shortly review the year, but before doing so give some account of my own experience, not so much because it shows a strikingly handsome profit, as that it may prove that an average bee-keeper may from even a small—and, alas! mine is all too small—an apiary gain not only an infinity of pleasure, but a good round sum of money as a practical memento of his year's attention.

It is impossible to set out in full—in fact, it is not necessary—a detailed account of the capital expense incurred, but current expenditure and income are given in detail in order to give those who have no experience in such matters some idea of the expenditure and income under these heads during the season now almost passed.

Capital Outlay on Four Stocks, Hives, &c.			£11 9s. 11d.		
Current expenses, 1885.			Income.		
	£	s. d.		£	s. d.
Sections and foundation	0	12 5	251 lbs. Honey sold.. .. .	15	10 0
Sugar	2	2 6	Prizes.. .. .	1	0 0
Zines	0	0 6			
Quilts and veils.. .. .	0	2 0			
Bottles, labels, &c	1	1 7			
Bees	1	10 0			
Time and interest on money.. .. .	1	12 6			
	£7	1 6		£16	10 0
Nett profit on the year				£9	8 6
Average per stock				£2	7 1½

Such is the statement of facts, relative to which I may add that in certain columns several statements of profits have appeared, but in not one of them did I see any charge made under the head of current expenditure for time and labour expended in management, nor yet a deduction made for interest on the money expended as capital outlay. If such deduction had not been made in the above statement the profits would have appeared greater—viz., £11 1s. instead of £9 8s. 6d. It is, however, only reasonable to make a full allowance for time, and to allow such interest, as it is but poor encouragement to a cottager to be told he can make a certain sum of money if he will count his own trouble and time as of no value. Fictitious balance-sheets—and any with such vital omissions must be fictitious—are misleading, and do not prove of the value which they might otherwise have been by giving data to which one who desires to influence another in the way of becoming a bee-keeper may turn for assistance.

It may be noted that the sum paid for sugar is high, but the explanation is that it is my custom to form sugar-fed stocks early in August, and so the consumption of syrup is somewhat greater than would be the case if such stocks were formed in September. Another circumstance needs some comment, and this time I refer to the price paid for bees. These bees, it may be said, are used each autumn to strengthen the stocks for another year, because as the non-swarming system suits me best in the majority of cases there are no surplus bees taken from honey stocks to add to those set apart for the following year. It is, I am convinced, a great mistake to be niggardly in strengthening stocks; the return is such that, as far as my experience goes, the somewhat decreased profit of the one year is amply repaid by a corresponding increase in the next, and so on.

The year itself has, on the whole, been favourable, but one great drawback has been the often repeated changes from hot to cold; one day bright genial honey weather, the next borrowed as it were from early spring. Around the district swarms have been numerous, but the yield of honey has not been anything more than ordinary. One thing is most satisfactory, and that is that my own stocks—two large Pettigrew's and two bar-frame hives—have all yielded a weight of honey nearly equal, and so the profit does not arise from one stock done a prodigious amount of work so much as from a general efficiency. And this must be the one great aim of all, the constant care of everyone who has bees to manage—to keep up all stocks to the highest point of excellence, not to allow the slightest deterioration, and if any becomes perceptible at once to set it right out of the profits of the year. Until the stock is of the same value, as it was at the preceding year's valuation there can be no profit. Many complaints have been made of honeydew having been collected in somewhat large quantities, and so the quality of the honey deteriorated, but this misfortune was here escaped, and the honey was of a good uniform quality, and in my opinion, if anything rather above the average in this respect. For the year now fast speeding on to its close we may well be very thankful, and if in the future no more adverse time shall fall upon us we may rest assured that the harvest will be greater still each year as it comes that though the price of honey will go down the larger quantity

gathered by each stock on the average, taking the country through, will bring up the profit to the same satisfactory amount as it was in the days of clumsy devices and bad management, when where one man kept bees on intelligent principles ten keep them now; when bees by their thousands were stifled to rob them of their store; when that store was presented for sale in unwholesome form contaminated with bee bread and brood; when but a few men were able to point with pride to their better system and management, and could with pride and just pleasure consider themselves to be almost, shall I say, the sole representatives and supporters of a just, reasonable, and humane system of management, whereby, although their store is taken, the hives are spared and kindness takes the place of heartless cruelty.—FELIX.

BEEES AND BEE-KEEPING.—An essay on this subject was read at the Wakefield Paxton Society's meeting on the 7th inst. by Mr. Frank Eccles, a young and enthusiastic apiarist of Newmillerdam, who in the course of a very practical paper showed the method he adopted for successful and profitable bee-keeping. The essay was made more interesting by a large number of appliances, the use of each being clearly explained, also specimens of the various kinds of bees which are kept, and the recommendations they severally possess being fully treated. A hearty vote of thanks to Mr. Eccles brought the meeting to a close. To judge by the interest shown in the essay the number of bee-keepers in this neighbourhood will no doubt be increased.—H. C.

TRADE CATALOGUES RECEIVED.

Ernest de Schamphelaar, 32, Rue de la Station, Wetteren, Belgium.—*Catalogue of Fruit Trees, Roses, and Ornamental Trees and Shrubs.*

Ketten Freres, Luxembourg.—*Catalogue of Roses.*

Robert Owen, Castle Hill, Maidenhead.—*Pocket Guide and List of Tuberos Begonias, Pelargoniums, Chrysanthemums, &c.*

* * All correspondence should be directed either to "THE EDITOR" or to "THE PUBLISHER." Letters addressed to Dr. Hogg or members of the staff often remain unopened unavoidably. We request that no one will write privately to any of our correspondents, as doing so subjects them to unjustifiable trouble and expense.

Correspondents should not mix up on the same sheet questions relating to Gardening and those on Bee subjects, and should never send more than two or three questions at once. All articles intended for insertion should be written on one side of the paper only. We cannot reply to questions through the post, and we do not undertake to return rejected communications.

Address (G. Reading).—The address you require is M. Louis Van Houtte Royal Nursery, Gendbrugge, Ghent, Belgium.

Fungus on Chrysanthemums (C. H. M.).—We have referred the matter to an expert, and will give you a reply in the next issue.

Distilling Water (C. S.).—We are not able to state any special "economical method of distilling water on a large scale," this not being a horticultural question.

Peach Trees Diseased at the Roots (John Boulder).—You are quite right in your opinion as to the cause of your Peach trees failing. The soil you have sent is permeated with the mycelium of a fungus as thoroughly as a brick of Mushroom spawn, and this in all probability is due to the leaf soil and perhaps decayed wood which were mixed in the border when it was made. The only cure is to remove the soil entirely from about the roots and have it replaced with some of a more loamy description mixed with chalk, lime, or lime rubbish.

Free-growing Grapes (C. G. S.).—Three varieties of Grapes that grow well, bear freely, and are as little liable to "disease" as any others, are the Black Hamburgh, the most useful black Grape for summer; Foster's Seedling, of which a few Vines will suffice; and Alicante for late use. The fruit of this is by no means equal in quality to Mrs. Pince's Muscat or Lady Downe's Seedling, but the Vine is a more certain bearer. If one end of your house is warm enough you might try a rod or two of Muscat of Alexandria, which is by far the best of all white Grapes. It is for obvious reasons impossible for us to recommend dealers.

Good Rhododendrons (J. W.).—The following are twelve excellent hardy, free-growing and flowering varieties that will probably suit you:—Charles Dickens, scarlet crimson; Charles Bagley, cherry red; Countess of Normanton, white, mauve blotch; Fastuosum flore-pleno, pale lavender, semi-double; Joseph Whitworth, lake, with cluster black spots; Lady Armstrong, pale rose, pink-spotted; Lady E. Cathcart, bright rosy carmine, dark blotch; Michael Waterer, brightest scarlet crimson; Mrs. Thomas Wain, pale rose, brown blotch; Mrs. John Clutton, white, good; Mrs. R. S. Holford, salmon pink, beautiful; and Sir Thomas Sebright, purple, bronze blotch.

Wintering Cannas (J. C. E.).—Cannas that have been taken up from beds in the London parks are packed closely together in soil under the stages of greenhouses in which Zonal Pelargoniums are wintered, and little or no water is given to them, nor is there any drip from the plants above. Your plants may be wintered just as well in pots in a greenhouse having a night temperature of about 45°, falling a few degrees in damp weather. They must be kept dry rather than wet, but not dust dry. Moisture is needed to keep the crowns fresh, not to support nor encourage growth in the winter.

Pears on a West Aspect (Surrey Amateur).—In good loam 3 feet deep on chalk we should not hesitate to plant any varieties of Pears or Plums we desired to cultivate against a wall in Surrey, on which the sun does not shine till 12 or 1 o'clock in the day; and, instead of having three trees only on a wall 40 feet long, we shall have more than twenty, training them a diagonal cordons. These are the cheapest trees of all (maidens), and this is the quickest method of covering a wall.

Scale on Pear Trees (W. J.).—The spurs you have sent are seriously infested with oyster scale (*Aspidiotus ostreiformis*), and it is impossible that trees in such a state can flourish. The wood is quite encrusted with the scale. You had better scrape them without injuring the bark, then dissolve three or four ounces of Gishurst compound or soft soap in a gallon of water, stirring in briskly while hot a wineglassful of petroleum, and apply with a brush, rubbing well into the crevices. Great good would be done by well syringing the trees with the petroleum mixture, but many parts would not be reached, and brushing would be more effectual. The preparation should be kept constantly stirred during its application. The name of the shrub of which you have sent a spray is *Leycesteria formosa*.

Growing Chrysanthemums (A Novice).—Every man who becomes successful was a "novice" some time, but by attentively picking up hints from others, an aptitude for learning by reading and observation, and thoughtful and persevering attention to small details of culture, many "novices" have become "masters" in Chrysanthemum growing, and other work in which they have been engaged. You will find on perusing the notes relating to Mr. Molyneux in another column that that renowned cultivator was entirely "self-taught" in the production of large and highly finished blooms. You will also perceive that there is a probability of his publishing the details of his method of culture, and these when they appear you had better read. Much has been published in the past, and we are informed that some of the largest blooms that have been exhibited this year were the result of the cultivator having turned to account the instructions that have appeared in this journal.

Preparing Beds for Roses (Merchant).—The preparation of the beds is of primary importance, and you seem to have set about it in a proper manner, only we think the manure should have been used more freely as well as the turfy loam. We have recently made a Rose border. First we put in 6 inches of drainage, bricks, and other loose material at hand, securing this with a layer of turves grassy side downwards; then a layer of manure 3 inches thick, and on this a layer of the old soil taken from the border, which was a good friable loam, and on this a layer of turf cut about 2 inches thick from a roadside and chopped up roughly only. Upon this a layer of manure, then the old soil and turf again, and so on to the top, the depth above the drainage 2 feet. This was done early in October, and it will lie until early January, when we shall put on an inch thickness of bones (half-inch) and 3 inches thickness, if possible, of charcoal, and then have the border turned over from end to end and the whole of the materials thoroughly mixed. The turf over the drainage will not be disturbed. We shall then plant and mulch with 3 inches thickness of short manure. We ought to state that this is for Roses under glass, though we make similar provision for the outside border. We should add more turfy loam to your beds, and add manure to the extent of a fifth of the other materials, incorporating them together. If your plant be a *Theophrasta* you may make cuttings of the ripe young shoots in spring, inserting in sandy soil with a surfacing of sand, and place in heat, covering with a bellglass. The *Araucaria* we are afraid you can do nothing with, only tolerate it as long as you can, and then obtain a young plant.

Pyramid Apple and Pear Trees not Fruiting (C. E. Bolton).—Judging from the wood sent, and your account of the trees, we think they make too much wood—i.e., are too vigorous, and do not ripen the wood sufficiently to insure the perfect development of the fruit. We know but one remedy, which is to restrict the root-action, and encourage surface roots by rich top dressings. We should form a trench a yard from the stem all round, and cut off all the roots, going down as deeply as the roots to make sure of severing all that extend beyond a yard distance from the stem. The trees against the wall should have the trench taken out at a distance of 4 feet from the stem. Before filling the trench the surface soil should be removed from the roots with a fork, and if they are deep carefully raise them and relay in fresh soil nearer the surface; but as the trees have not been disturbed at the roots for some years, it will not answer to interfere too much with them, therefore confine the lifting to the uppermost roots. The trench should be filled up again and the soil trod firmly as well as that over the roots, which should not be covered deeper than 3 or 4 inches with soil. When the work is complete mulch with 3 inches thickness of well-decomposed manure. The Apples you name are free bearers, and so are the Pears. Are you in a smoky locality?

Names of Fruits.—The names and addresses of senders of fruit to be named must in all cases be enclosed with the specimens, whether letters referring to the fruit are sent by post or not. The names are not necessarily required for publication, initials sufficing for that. (*A. J. Brown*).—All three Pears are *Beurée* Del. (*N. H. Pownall*).—Apples: 1, Norfolk Stone Pippin; 2, Lewis' Incomparable. Pear: No. 1, Duchesse d'Orleans; 2, Epine du Mas. (*F. J.*).—1, *Beurée* de Wetteren; 2, *Doyenné* du Comice; 3, *Beurée* Superfin; 4, Probably *Doyenné* du Comice; 5, *Carel's* Seedling; 6, London Pippin. (*E. M. B.*).—1, Ribston Pippin; 2, *Doyenné* Defays; 3, Knight's Monarch; 4, General Todleben; 5, Red *Doyenné*. (*J. Watson*).—1, Beauty of Kent; 2, Cockle's Pippin; 3, Brad-dick's Nonpareil; 4, Marie Louise d'Uccle; 5, Glou Morceau; 6, Chaumontel. (*L. G.*).—1, Golden Reinette; 2, Bess Pool; 3, Uncertain.

Names of Plants.—We only undertake to name species of plants, not varieties that have originated from seed and termed florists' flowers. Flowering specimens are necessary of flowering plants, and Fern fronds should bear spores. Specimens should arrive in a fresh state in firm boxes. Slightly damp moss or soft green leaves form the best packing, dry cotton wool the worst. Not more than six specimens can be named at once. (*B. J. B.*).—*Laurus nobilis*. (*John Cameron*).—1, *Retinospora ericoides*; 3, *Retinospora filicoides*; 4, *Thuopsis dolabrata*; 5, *Cupressus Lobbi*; 6, *Cupressus Lawsoniana*; 7, *Arbutus Unedo*. 2 will be named next week. We do not undertake to name more than six specimens at one time. (*S. W. Yorks*).—As you supposed, the specimen received was completely crushed, but it is evidently a *Streptocarpus*, probably *S. Rexi*.

WINTER DIET.

THE FLOCK.

If we were asked for a golden rule for guidance in feeding animals our reply would be, "Avoid extremes." Plain teaching is our aim, and we strive to avoid a too scientific or technical tone; yet we are bound to keep well in view the importance, nay, the absolute necessity, of combining science with practice, and no farmer can have clearness of aim and purpose unless he has a sufficiently clear understanding of cause and effect in its relation to his work. Take, for example, the well-known fact that a diet of Turnips or Swedes frequently causes abortion in ewes. Why? In cold, often very wet weather, a pregnant ewe will consume from 20 to 30 lbs. of Turnips, which if not frozen are certainly at a very low temperature when eaten. In point of fact, it is a dietary consisting of nine-tenths of water so cold that the temperature of the body is lowered; there is a falling off in condition, the fetus lacks nourishment, is chilled, starved, dies. Cause and effect are surely before us here. The remedy is equally clear—reduce the quantity of roots by one-half or two-thirds, according to the condition of the sheep; substitute sound dry food in the form of mixed straw and hay chaff with bran or crushed Oats if the condition is very low, and see that the sheep are able to rest in comfort. Very simple all this, is it not? yet of such vital importance that it marks the difference between success or failure. Do not forget that exposure to cold and wet, as well as the consumption of half-frozen Turnips, lowers the temperature of the body, causes an unhealthy strain upon it because so much heat is absorbed, and much food is wasted in raising the temperature of the superabundance of cold water contained in the Turnips.

We desire to call particular attention to this important matter now, for the critical time for the breeding flock is

upon us. To fold pregnant ewes upon Turnips or Swedes now, or rather from the present time till after the lambing, is to court failure; it is a reckless proceeding of which no really intelligent man can be guilty. It is still done, however, and last year we again had urgent inquiry for a remedy for abortion after the mischief was done. A mixed diet, kindly gentle treatment, rest upon a sound dry pasture; in a word, let us follow the dictates of common sense in feeding the ewes, and in our own care for their external comfort. May we go a little farther, and ask our readers to try and see what food does for animals? Food consists of two distinct parts—organic and inorganic. Organic food consists of combustible substances divisible into two classes—nitrogenised and non-nitrogenised. The office of the first is to form tissue and blood; of the last to maintain heat and promote respiration. Inorganic food, really the residue of the other, supplies bone and enters into the juices of the body and into the composition of the blood. Our object here is to show that food does something more than form tissue, bone, and blood. It maintains heat, without which no animal of the farm can be in a healthy thriving condition. To expose animals in a bleak wind-swept field, to keep them penned up in a fold, standing hour after hour in a mud puddle several inches in depth, to give them nothing but cold wet food; all or any of these things tend to exhaust the strength, to waste the heat, to lower the condition.

A short time ago mention was made of the use of unthreshed Oats as an economical article of food, and we may here strongly recommend the chaffing of unthreshed Oat sheaves for sheep. In analyses of grain and straw we are shown the various proportions of constituents in one hundred parts, and Oats certainly compare favourably with other cereals, the grain containing of water, 13.09; flesh formers, 11.85; heat and flesh producers, 63.34; and the straw of water, 12.06; flesh formers, 1.63; heat and fat producers, 39.98. Compare these proportions with those of Swedes, which give of water, 89.40; of flesh formers, 1.44; of fatty matters hardly an appreciable proportion, and we see how admirably chaffed grain and straw of Oats is calculated to correct the deficiency of the roots. It is undoubtedly true that we have repeatedly advised that ewes should be kept off the roots till after lambing, and this course has been adopted as the only safe one while so much careless practice is known to exist. But in safe hands both Swedes and Turnips may be used at any time in moderation, and carefully mixed with other food.

The value of other straw must not be overlooked. Barley, Pea, and Bean straw are all nutritious, and are used unchaffed in racks, affording a frequent change and much wholesome nourishment to the sheep. We have strong faith in keeping pregnant ewes in high condition, our aim being to obtain fine sturdy lambs early in the season, so that we may draft a certain number to be brought on for market as fat lambs, and to select the best ewe lambs for breeding in the first year. Two flocks of such lambs of the current year have taken the tups, and we have reasonable hopes of obtaining good lambs from them, for they have been well fed to bring them forward in growth, the tups being put with them a month later than with the older ewes. These lambs have had some cake, but now that corn is so cheap it is used instead of cake, a mixture of Barley, Peas, and Beans being ground, and forming excellent nourishing food, a fair amount of which will be used for them throughout winter, and we believe that this gain of a year in breeding will well repay us for the extra outlay in food which it involves.

(To be continued.)

WORK ON THE HOME FARM.

The killing and curing of bacon hogs is now being done at the home farm, nice compact animals of about 250 lbs. dead weight being selected for this purpose, and we have plenty to choose from, our stock of pigs being considerably enlarged to consume cheap corn, which just now at any rate answers best if turned into pork, and so passed into the market, such

pigs producing about £6 apiece under the auctioneer's hammer. We regret having had to expend a considerable sum of money in stocking the five farms which we have in hand with pigs. This is undoubtedly bad practice, but in our case it was unavoidable for this winter. Another season we hope to do better by having enough breeding sows on each farm. Whether pork is cheap or dear pigs bring a quick return for money expended upon them, no animal growing or fattening so fast. Perhaps stubble pigs answer best. We saw a fine herd out upon the stubbles of a large farm this autumn that at a reasonable rate must have brought the wise owner considerably upwards of £1000 by this time. Swine fever is still rampant at many farms, and the sale of young store pigs is prohibited in open markets. Why should pigs be kept in the filthy state in which so often see them? We have had the walls of all our piggeries thoroughly cleansed with washings of fresh-slacked limewash, the yards cleared of any accumulations of old manure, and plenty of fresh straw kept littered about yards and beds. We use large sheds, opening into yards of proportionate size, for pigs, from forty to sixty pigs being kept together in each of them, and we find this plan answers well, the feeding and littering being much less laborious than when the pigs are in separate styes.

Turkey poults are now in season, and we have plenty of nice forward birds that for several weeks after harvest were out upon the corn stubbles daily. The important thing in turkey breeding is to have plenty of forward broods, to which end there must be kept plenty of breeding stock, old birds always commanding high prices if fattened specially for Christmas, for it is size that tells in the turkey market—the larger the kind the higher the price. For home consumption we try to have enough full-grown plump young hen birds, which are considered to be best for the table of a connoisseur. An excellent supply of eggs is now afforded by the early chickens which were saved from the March and April broods. It is only by having this done regularly year by year that we are able to insure plenty of eggs in winter, when old hens have ceased laying and do not begin again till spring.

MR. W. J. MURPHY, CLONMEL.

THIS is a familiar name to readers of horticultural and agricultural literature. A portrait of Mr. Murphy appeared in *The Irish Farm* of the 14th inst., with the following appreciative remarks:—

"Mr. W. J. Murphy, whose portrait we give to-day, has been one of our correspondents in both the farming, gardening, and industrial departments for many years. He is a graduate of the Government Farming Institute at Glasnevin, where, in open competition, more than twenty years ago with eighty others, he won one of the first places. The Albert Farm, as it was called, had then for superintendent Dr. Kirkpatrick, who was succeeded by Professor Baldwin, now of the Land Commission. Here for more than two years Mr. Murphy had the benefit of sessional lectures also from W. K. Sullivan, Ph.D., now President of the Cork Queen's College; Dr. Hodges of Belfast; Dr. Moore, Ph.D., R.D.S., Botanic Gardens; James M'Donnell, M.A., and many other eminent men in various spheres and subjects. A machine accident at this time deprived him of his left hand and seriously interfered with some 'high hopes and pious intentions' then entertained. A man of less energy and independence of character would have gone home to his father's farm in Carlow, looked after the cattle, or ended his days in some listless occupation. He faced the world, took the first position that offered, and was appointed head master and agriculturist to the Local Board of Clonmel just twenty years since. Instead of settling down to a hum-drum official existence, Mr. Murphy has spent his vacations in acquiring topographical and other knowledge, and adding to a well-stocked fund of general information, especially on gardening, farming, and collateral matters. He wields a versatile, graphic, and fluent pen, combined with considerable grasp of observation. In all his correspondence, so far as we know, it may be repeated of him, he never lost a friend or made a foe—if he cannot serve mankind in general, or individuals in particular, he will do them no harm; and this is no small commendation in those exciting times."

REMARKS.

8th.—Dull, with a little drizzle in evening.
 9th.—Dull morning; drizzly afternoon and evening.
 10th.—Drizzly day and evening.
 11th.—Drizzle all day.
 12th.—Very dense high fog; gas necessary all day.
 13th.—Cloudy, with fog in morning; fine afternoon; foggy evening.
 14th.—Wet up to noon, then fair; fine evening.
 An exceptionally dull week, with fog and cloud, and of course very small range of temperature.—G. J. SYMONS.

WREATH-MAKING.

I HAVE been tempted to offer a few remarks on making memorial wreaths, seeing that their use has now become so popular. It is indeed a prominent branch in almost every nursery establishment, and one which is rapidly on the increase. It is not my intention in these few remarks to lay down any hard-and-fast rule, as this is next to impossible, and will depend to a great extent on the taste for floral arrangements which the operator has acquired. I wish to assist the younger members of the gardening community, especially those who, being in private establishments, do not get the insight into this work as do those who are educated in nurseries. Thus a few remarks on the rudiments of wreath-making generally from a practical worker may prove helpful.

The first step after having decided the required size of the wreath when completed will be to form a circle, which is most frequently used, and for which I have adopted the name of "skeleton." These skeletons are very deceptive, and it is one of the commonest errors with the uninitiated to make these much too large, and if the supply of flowers be somewhat scant the wreath in turn will present a very lean appearance. With a view of overcoming this I will briefly cite one or two examples. Presuming, then, that a wreath when complete is required to be about 12 inches in diameter, the size of the skeleton on which to build it should not exceed 6 inches in diameter when flowers such as Chrysanthemums and Camellias are in season, but which may be increased to 7 or 8 inches when choice flowers, as double Primulas, Bouvardias, Roman Hyacinths, and Lily of the Valley, are employed. The diameter of the first-named may be a surprise to many; it is, however, fully justified by experience, and is more readily understood if the breadth of a very ordinary Chrysanthemum, Camellia, or Eucharis be taken into account; with a moderate-sized flower of either of these, and some smaller sprays to furnish the sides, and with Fern fringing the inner and outer margins, it will be seen how easily the size may be increased twofold. My idea of a full-sized wreath when finished and ready for use is 15 or 16 inches in diameter (above that size I term them specials), and for this size a skeleton of 9 inches diameter will be ample.

Having shown, then, something of how the size may be gauged, we must now construct the skeleton, and for this purpose galvanised iron wire will be found to answer well. Having got this into shape and of required size, next secure a hazel or willow to it and round the interior. This will prevent the wire revolving in the hands of the operator, and which frequently misplaces a flower or two, thereby causing inconvenience and annoyance. Having secured the hazel or willow to the wire, some fresh green moss should be bound tightly over it with small twine, which when finished should be slightly flattened. When this is done a firm surface about an inch wide will be the result, and all will be ready for placing the flowers. There are several other ways of preparing these skeletons, some binding them with cotton wool,

which I object to, on the ground of a green base for the flowers to rest upon being more suitable. Further, when the bulk of the flowers are arranged it frequently happens that by inserting small choice bits here and there a great improvement is made in the wreath. This may be done easily where moss is employed as a foundation, having a piece of stem wire to pierce the moss, and doubling it back as it emerges from the opposite side secures it in position. When cotton wool is used it will not allow of wire passing through it. For these reasons, and for the fact that moss retains the moisture considerably longer than cotton wool, which robs the flowers of the little moisture which is about them, I am strongly in favour of a moss foundation. Wreath skeletons made in various sizes are sold by horticultural sundriesmen, but all I have seen are anything but suitable for the purpose. They consist of two wires arranged in circles at about 1½ inch apart, and fixed by about four cross wires. This leaves a large cavity with which it is difficult to deal, and also uses an immense amount of binding wire in the work of arranging the flowers. One of the simplest contrivances I have seen is made of block tin cut in circles about three-quarters of an inch in width, or they may be made of scraps and soldered together. In the latter way, though a little more trouble in making, they are firmer than when cut out in one piece. Any tinman will make them. I have used these in quantity in sizes ranging from 5 to 12 inches in diameter.

It may not be out of place for a moment to refer to the arrangement of a wreath, though, as I before remarked, much will depend on individual taste. Presuming, then, the flowers are cut, such as Bouvardias, Lily of the Valley, Roman Hyacinths, Gardenias, Tuberoses, Eucharis, Azaleas, and double Primulas will need wiring, and Camellias and Roses will need piercing, the former on account of the custom to twist off the flowers with no wood attached, hence stemless, and to prevent them from falling; and the latter to keep them from becoming too gaping. If at hand some small sprays of Cupressus Lawsoniana will be serviceable, and assist in the economising of Maidenhair Fern, which is generally a scarce article at this time of year. Begin the arrangement, then, by laying a spray of Cypress, and upon which place a frond of Maidenhair, the latter somewhat protruding and not too flat; then comes a Camellia, Eucharis, or Gardenia—or, in fact, any of the larger and more prominent flowers to occupy the centre, filling in the sides with smaller flowers. Lily of the Valley, Deutzia gracilis, and Roman Hyacinths do well for fringing the sides. Continue the use of the Cypress, and insert here and there a small spray of Fern, firmly binding them as you proceed, and using a small pinch of moss on the stems of the flowers. This will keep the wire from cutting the stems, and will also supply moisture to them. Always avoid a heavy arrangement and overcrowding, and allow as far as possible the flowers to assume their natural position. Use the flowers in as much variety as possible, and, if procurable, a few well-coloured sprays of Panicum variegatum will be found very pretty and effective jutting out here and there. It is productive, too, of lightness and elegance, which should characterise the arrangement throughout, and with it and Maidenhair Fern interspersed among the flowers a very pleasing and elegant wreath may be formed. In case of packing this is easily done by placing a stick across the skeleton, allowing it to rest on either side under the flowers, and attach a string to its centre; then make two holes in the bottom of the box, pass the string through and fasten securely underneath. It will travel safely thus, and the person unpacking it will see at a glance how it is secured.—J. H. E.

THE ONION AS A REMUNERATIVE CROP.

I AM induced to make the following remarks from reading the paper by "Utilitarian" in last week's issue of the Journal, "Estimate of Vegetables—Onions." He says:—"As a crop for

market Onions are important, if, indeed, it is not one of the most valuable from a paying point of view." I quite agree with him in this. The Onion has been a universal favourite from the remotest period of history, and at the present time there are few gardens in this country, or indeed in Europe, but where it is cultivated and enjoyed by all. Its cultivation is well known, and great crops are raised annually by market and private gardeners all over the country; and yet, to judge from the enormous quantities that are imported from the Channel Islands, France, Spain, and Portugal, we do not grow sufficient to supply the home demand. As a field crop I think there are few that pay better. When well grown the produce will yield from £50 to £60 per acre, with not much more labour than that required to grow Turnips. I think that farmers in the present depressed state of agriculture should turn their attention to this crop. If it pays market gardeners to grow Onions at a rent of £8 and £9 per acre it will surely remunerate farmers who have only to pay from 30s. to 40s. per acre.

The Onion succeeds best in rich ground deeply tilled, but with generous treatment it can be grown successfully for years in succession on light soils when heavily manured. To insure a good crop it is necessary that the seed should be sown as early in February as the state of the soil and weather will permit. When the soil has been thoroughly prepared the seed should be sown thinly in shallow drills 1 foot apart. After it has been covered in, and the ground raked over all the labour the crop will require after until ripe is frequent hoeings between the rows to keep weeds down. The plants will be much benefited by a sowing of soot or wood ashes. Some time in May it will also act as a preventive against maggots injuring the crop.

For the field or the principal garden crops there is no system I know equal to that of thin sowing and allowing every seed that germinates to grow. When this method is adopted the labour of thinning is saved, and the produce is greater in weight and as good in quality and keeping properties as those sown thickly and thinned out afterwards. I have practised thin sowing for the last fifteen years, and can thoroughly recommend it to others. Several market gardeners in this neighbourhood have adopted the system, and prefer it now to all others. They find it pays them better to sow thinly and allow the plants to fight the battle of life for themselves in preference to thinning them out to any given distance.

Onions can be grown to a greater size by sowing the seeds in pots, pans, or boxes in the middle of January, and placing them in a gentle heat, and keeping the plants growing in frames till the middle of April, when the weather is mild, and then planting them out in rows 1 foot apart, and 6 inches apart in the rows. The finest Onions I have seen grown in this country were exhibited at the Edinburgh International Show some three years since by Mr. Murray of the Gardens, Culzean Castle, Maybole, Ayrshire. The seed was sown in boxes in January as described—the variety Cranston's Excelsior, and for size and finish they equalled the best imported Spanish Onions.—A PETTIGREW, *Castle Gardens, Cardiff*.

NEW CHRYSANTHEMUMS.

LAST week a review of the principal French varieties of the past six years was given, and this may be now supplemented by a list of those that have been certificated in England during the same period. It may be noticed in passing that some of the French raisers have occasionally sent out different varieties under the same name, a practice which cannot be too strongly condemned, as it obviously must lead to much confusion. We have an instance this season in Roseum superbum, for which Messrs. Jackson & Son obtained a certificate at Kingston in 1883 for a variety bearing the same name, but quite distinct from it if my memory serves me rightly. Referring to the list given by M. Ghys and noted last week, it appears that in 1880 Lacroix sent out a variety named "Rosa superba," described as soft rose-coloured, and in 1883 Delaux announced a variety named "Rosea superba," "rose lilac shaded and pointed with yellowish buff." It is probable that the one certificated at Kingston in 1883 is Lacroix's variety, and that of this year is Delaux's, but I should like to have some more information on this matter. L'Aurore Boréale of Lacroix (1881) and of Delaux (1884) seems to be another instance of the same kind. Carmen de Reydellet (1884), a Japanese, and Carmen of Delaux (1884), a Chinese, afford another example; Flocon de Nieve of Lacroix (1881) and the same name of de Reydellet (1885), Tendresse of Lacroix (1881) and of de Reydellet (1885) furnish other examples of the same practice. According to the descriptions given by M. Ghys these are all distinct, but I have not the raisers' descriptions to refer to.

Sending out the same varieties under different names is certainly much more culpable, and Mr. Harman Payne has done well in

clearing up what appeared very much like a case of this kind in Mdle. Lacroix and Pureté, which seemed to be identical. From his note it may be fairly supposed that there are two distinct varieties under these names, but what has been generally grown as Mdle. Lacroix is really the true Pureté, while the former is either not in cultivation here or scarce.

Turning to the records of varieties certificated in England we find that in 1879 no Chrysanthemum was so honoured at the leading London shows, while in 1880 there were only two, both English raised—namely, Lady Selborne (Japanese) and Angelina (incurved). In 1881 also there were only two certificated—Lady Selborne again and Rex Rubrorum (Japanese). Five were certificated in 1882—incurved, Lord Wolseley; Japanese, F. A. Davis, since found to be identical with Jeanne Delaux and M. Desbrieux; Pompons, La Petite Marie; and reflexed, Crimson King. The year 1883 saw twelve additions to the list of certificated varieties, comprising the following—Incurved, Bendigo, Jeanne d'Arc, and Lord Alcester; Japanese, Comet, M. Astorg, Mdle. Lacroix, Mons. Dufour, Mons. Henri Jacotot, Salteri, and Roseum superbum; Pompons, Mons. Darnaud; and reflexed, George Stevens.

A most rapid advance was made in 1884—a greater number of French varieties was imported and brought before the Floral Committees of the Royal Horticultural Society and the National Chrysanthemum Society, no less than twenty-five being deemed worthy of certificates as follows—Incurved, Lord Wolseley (also certificated in 1882); Japanese, Beauté des Jardins, Carmen, Criterion, Fernand Féral, Flamme de PUNCH, La Bien Aimée, La Pureté (now decided to be identical with Mdle. Lacroix), Madame de Sevin, Mdle. Lacroix, Mons. Astorg, Mons. Tarin, Roseum Pictum, Souvenir du Japon, and Val d'Andorre; reflexed, Cullingfordi (also admitted this year as a Japanese at the National Society's Show); Japanese Anemones, Fabian de Mediana, Mdle. Cabrol (raised or sent out by M. Marrouch in 1879), and Sœur Dorothee Souille, still older according to M. Ghys, having been sent out in 1877; Pompons, Anais, Nellie Rainford, Star of Whyke, and Val d'Or; single, White Perfection.

After such a number as this it might have been expected that a lull would follow, but this has not been the case, for twenty-four have been certificated up to the present time this year, and it is quite possible that the National Society will find some others worthy of honour at their last two meetings of the season. The awards of the Floral Committee during the past two years have added materially to the number of certificated varieties, and it is an open question if they have not distributed these honours too liberally.

It is at least evident that other societies have been more sparing in this respect, for in 1884 the National Society's Committee certificated thirteen varieties, two of which were honoured elsewhere; this year the same body has certificated nineteen varieties, four gaining similar awards at other shows and meetings in London. Thus out of a total of thirty-two certificates only six have been confirmed by other societies. Of course it may be represented that many more novelties have been submitted to this Society than elsewhere, which is undoubtedly true, but in any case it behoves the Society to be economical with their certificates, or they will soon lose the standard value they ought to possess.

CHRYSANTHEMUMS CERTIFICATED IN 1885.—JAPANESE.

BELLE PAULE (E. Molyneux and Jackson & Sons).—This has got into cultivation under the erroneous name of Belle Pauline, that given above being the title under which it was sent out by M. Marrouch in 1881. It was not, however, until this season that it attracted much attention, Mr. Molyneux having shown it exceedingly well at the Crystal Palace and Kingston, six grand blooms being staged at the latter Show in the class for six of one variety, Japanese. The florets are flat, drooping or twisted, white margined with lilac-purple very clearly defined, and this gives a most distinct character to the variety. It will probably be in great demand this season. Certificated at Kingston.

BRISE DU MATIN (Forbes).—The blooms of this are well adapted for exhibition, being large and of fine substance; but it has been shown in few stands. It is one of Delaux's 1884 varieties, and has broad recurring florets of a bright rose tint. Certificated by the National Society.

JUPITER (J. Veitch & Sons and N. Davis).—Of rich colour, a fine shade of reddish crimson, the florets slightly fluted and twisted in the centre, the under surface being purplish. (Delaux, 1885). Certificated at Kensington and by the National Society.

L'ADORABLE (J. Veitch & Son and N. Davis).—A large bloom with flat broad florets, opening bronze and coming bright yellow afterwards. Certificated by the National Society.

LAKME (N. Davis).—A decorative free-flowering variety with blooms of good substance, golden-orange in colour. Very orna-

mental as a conservatory plant. (Delaux, 1885). Certificated by the National Society.

L'ÉBOURIFFÉE (H. Cannell & Sons).—Blooms large and effective, very bright yellow. I have seen very little of this, and cannot express an opinion as to its merits. It is one of de Reydellet's 1885 varieties. Certificated by the National Society.

L'ILE DES PLAISIRS (Forbes).—A pretty variety, with blooms of medium size, the florets fluted or nearly flat, bright bronzy red on the upper surface, and with a golden reverse. Certificated at Kensington.

MADAME JOHN LAING (J. Laing & Co.).—An excellent variety. The blooms large and full, with broad flat florets, white, with a tinge of rosy purple or blush. It is a capital exhibition variety. (Delaux, 1885). Certificated at the Crystal Palace.

MAIDEN'S BLUSH (G. Stevens).—A seedling raised from imported seed at Mr. Stevens' Putney Nursery, and has been there tried for two seasons satisfactorily. The florets are broad, flat, forming a full, large, handsome bloom blush-tinted or creamy white. The plant is strong in habit and free. Certificated at Kensington and by the National Society.

MANDARIN (N. Davis).—An early-flowering variety, very floriferous, and will prove useful for decorative purposes. The blooms are of good size, creamy tinted, with a tinge of rose. Certificated by the National Society.

MARGOT (Forbes).—This variety (Delaux, 1883) was certificated last year, and this award was confirmed at the meeting of the National Society on October 14th this year. It is a charming variety with fluted florets of a rich rosy colour. The bloom large and of good form.

MONS. FREEMAN (Wright).—Very distinct in colour, a peculiar lilac pink or peach, the florets slightly fluted and recurved, except at the points, which are indented or turbinate and turned upwards. In the early stages the florets are incurved so much that the variety resembles a small incurved bloom. When first shown it did not appear first-rate, but it improved later in the season, and though not large it is of good substance, and would make a telling colour in a box of Japanese. Certificated by the National Society.

MONS. JOHN LAING (J. Laing & Co.).—Florets fluted, recurved, and twisted, bright bronze red, very rich and dark in some blooms, but occasionally lighter with a yellowish tinge. The blooms are of good substance, and it will probably make a useful exhibition variety. (Delaux, 1884.) Certificated at the Crystal Palace.

MONS. MOUSILLAC (Forbes).—One of Delaux's varieties sent out in 1883. The blooms are large and full, of a most brilliant reddish crimson colour. Certificated by the National Society.

MONS. A. VILMORIN (J. Veitch & Sons).—A medium-size bloom with fluted slightly recurved florets, varying from orange-red to nearly yellow. It is pretty and free, but appears rather too small for exhibition; more after the style of *L'Or du France* or *L'Or du Rhin*. (Delaux, 1885). Certificated at Kensington.

ROSEUM SUPERBUM (Jackson & Son).—This is referred to in the former portion of these notes, and, as there remarked, seems to be distinct from the variety previously certificated under the same name. The florets are fluted and recurved, or slightly twisted, forming a medium-sized bloom, the colour rose with a yellowish tint. Certificated at Kingston.

VAL D'ANDORRE (Wright).—A handsome variety, which has come out remarkably well in some of the best stands of Japanese at the leading shows. The florets are flat and broad, or sometimes slightly fluted, bright red on a yellowish ground, the blooms large, full, of good substance, and the distinct colour renders it valuable both for exhibition and decoration. Certificated at Kensington and by the National Society.

MISCELLANEOUS VARIETIES.

All these were certificated by the National Society.

BELLE NAVERAISE (Wright).—A hybrid with something of the incurved character, but the florets erect, pure white, forming a good-sized bloom.

BRONZE QUEEN OF ENGLAND (J. Carter & Co.).—Exactly the same style of bloom as the ordinary Queen of England, but of a true bronze colour.

FIBERTA (H. Cannell & Sons).—A Pompon; flowers bright golden yellow, of moderate size.

MRS. MARDLIN (Mardlin).—This is a pretty Pompon of a clear pale rose tint. It is a sport from President.

POMPONUM (N. Davis).—An early-flowering free Pompon with orange-coloured blooms of medium size.

YELLOW GLOBE (W. Martin).—A bright golden yellow sport from White Globe, exactly the same style of bloom, and very promising.

As a selection of the best of the preceding I should name the following:—*Belle Paule*, *Brise du Matin*, *Jupiter*, *Madame John Laing*, *Maiden's Blush*, *Margot*, *Mons. John Laing*, and *Val*

d'Andorre. These are excellent varieties, which have been well proved this year for exhibition purposes. All the others are useful for decoration, the early Japanese particularly so, as they afford blooms most abundantly. There is no doubt that the Japanese are rapidly gaining popular favour, and while the florists still attach the greatest value to the incurved, the public admire the less formal and brighter coloured type. For cutting or general decoration the Japanese much surpass most of the incurved, freely grown specimens of the former being exceedingly ornamental. Several of the Anemones are much appreciated for this purpose, and the single varieties are also very graceful.—LEWIS CASTLE.

ESTIMATES OF VEGETABLES.

CELERY.

TAKING the cost of manure, preparation of the plants, and labour entailed, this is not a very remunerative crop, at least not as far as I have experience; still, its cultivation is one of the very best preparations of the ground for the succeeding crop, as the ground gets well manured, deeply stirred, and exposed to the ameliorating influences of the atmosphere. Besides, it can be taken, and usually is, after Broccolis, spring Cabbage, or early Peas, so that between the two crops the result for the year is not discouraging. In some districts it is a practice to make the trenches in spring, and plant the spaces between with early or Ash-leaved Potatoes, which crop is off before the Celery needs much cultural attention; indeed, the Potatoes are earthed from the trenches intended for Celery in some instances. In the fen districts the trenches are so arranged as to be flooded with water at will from the dykes; and as Celery likes nothing so much as a broiling sun and plenty of water, it makes rapid progress in the months of July and August, when that in gardens can barely be kept growing in hot weather. The fen Celery is prime in late summer and on to early winter, bringing prices that the garden-grown produce fails to reach, though entailing twice the labour in cultivation, especially in watering. I do not find garden Celery pay until winter is fairly set in, and the later the better the returns. It is tantalising to hear of Celery bringing 3d. per head to the retailer, whilst the grower gets 6s. per dozen bundles of a dozen heads each. He has rent, taxes, manure, and labour to provide out of a halfpenny, whilst the middleman with not a tithe of the outlay pockets 2½d. Even if the retailer gets his penny to the grower's halfpenny it is not difficult to discern on which side is the advantage, and form no slight indication of what presses unduly on the industrial energy of the grower.

The varieties of Celery are numerous. The best for market are those combining size with high quality. I find none equal to Wright's Giant White. It is large, robust, solid, crisp, superior in flavour, and very hardy, good alike as an early and late variety. Of pink or pale reds Ivery's Nonsuch for autumn and early winter use carries off the palm, being large, solid, fine-flavoured, in every respect excellent. Leicester Red or Major Clarke's is an excellent variety, and keeps well, being the best red Celery in cultivation for any purpose. Those three I can strongly recommend, along with Sandringham White, where a white Celery is required late in spring, as I find it the Celery for keeping a long time fit for use, having had it good as late as April. I ought to state that Williams' Matchless Red is a capital variety and one that winters well; indeed, last year it brought 9s. per dozen bundles of six each, when other varieties had to be rejected from the number of their decayed heads. Winchester Red is also apparently an excellent variety, and for private consumption is the one chosen to go with Sandringham, as I find these stout short-growing sorts in better repute than the larger varieties, and as a pink is sometimes wanted I have it in unimpeachable quality in Sulham Prize.

White Plume I had this season for the first time, but I can say but little in its favour; indeed, I had not a plant in a score, hardly one in fifty, that was White Plume, though I had the seed from one of the best seed firms, and who have served me very satisfactorily for many years. The crop turned out well. I had nearly a thousand of it, and setting aside the plants of White Plume which were of no account from a marketable point of view I found it gave solid heads, crisp and good, blanching readily. In what it differs from Cole's Superb Crystal White I failed to discover, and whoever has grown this need not be long in finding White Plume, especially if he will take to sowing old seed. In fact, I sent you over twenty years ago a white Celery found amongst plants of the then noted Manchester Celeries which you were good enough to state in your correspondents' column might be useful for decorative purposes. If White Plume is no better than I have it in the miserable self-blanching plants I fail to see its use or in what way it is likely to be ornamental, and it certainly will not be grown again by—UTILITARIAN.

JUDGING PEARS AND GRAPES AT THE BATH SHOW.

In the report of the above excellent Show your reporter says that "Mr. Nash was also first in the class for any black Grapes, but was some-

what favoured, as his bunches of Alicante, though very fine, were not well coloured. Mr. W. Taylor was again second with the same variety, small in bunch, but beautifully finished, and that Mr. Chedzey was third with fine bunches of Alicante, which 'many' seemed to think should have been first." As one of the Judges who made the awards in the fruit classes I cannot allow this statement to pass unnoticed, although I would, for obvious reasons, prefer not being called upon to justify our decisions. Mr. Nash's bunches were very fine, compact, and even, but slightly deficient in colour in the lower part of the individual bunches. On the other hand, Mr. Taylor's bunches were, as stated, smaller—considerably smaller—less compact, being gappy, and better coloured, but slightly rubbed. Hence their being placed second instead of first, which position they would have occupied had the bunches been more compact irrespective of size, or of the fact of their having been rubbed. In short, the point or two which Mr. Taylor's gained over Mr. Nash's bunches in colour they more than cost in size and symmetrical appearance; and what Mr. Chedzey's bunches gained over Mr. Nash's bunches in size they more than lost in their "dirty" and somewhat loose appearance, as well as want of colour. Yet these are the bunches which your reporter says were "fine" and should have been first, a position which, curiously enough, he had already hinted ought to have been accorded to the second-prize stand. It may be interesting to note that Mr. Taylor and Mr. Nash occupied the same positions with the same Grapes at Bristol the following week, the awards being made by such noted fruit-growers as Mr. Austin of Witley Court, and Mr. Bethel of Ashton Court.

Now for the "Pear question." In reference to the awards in the Pear classes your reporter says that the "Judges followed the 'rather unusual' course of awarding the prizes to the generally evenest in appearance, all being fit for table;" adding, "As a consequence that much the finest collection, staged by Mr. Bannister, was passed." The fact is, the collection referred to consisted of six dishes of six fruits each, the fruits on three dishes, including good examples of Pitmaston Duchess, were large, while those on the other three, including one of unripe Easter Beurré, were considerably less, presenting, I may say, by way of illustrating the effect thus produced, as well as my meaning, the appearance that a stand of six Chrysanthemum blooms consisting of three large-flowered varieties and three Pompons would produce. Your Chrysanthemum-growing readers know perfectly well that such a stand if placed in competition against several other stands of a like number of even-sized blooms of a size between the two varieties indicated would, in consequence of the want of uniformity in the collection of blooms, be also "passed," yet this practical standard is what your reporter terms "the rather unusual course to follow" in connection with ripeness, quality, and finish of exhibits. Our awards throughout the fruit classes were quite consistent with this "standard of excellence" with which we started. In the collection of six varieties of Pear class each fruit in the prize lots was ripe, the fruits being even and of good quality, and the collective dishes of fruit uniform in point of size.

In conclusion, I venture to say that if such admittedly clever and successful fruit-growers and exhibitors, and therefore excellent judges, as Messrs. Coleman and Wildsmith had rejudged the two classes in question, or, indeed, all the fruit classes at the recent Bath Show, they would not have disturbed the awards which were made by my colleague and myself. I am extremely sorry to be obliged in defence of my own reputation as a fruit-grower and judge to point out in public the defects of any gardener's exhibits. But, on behalf of my coadjutor and myself, I could not allow such statement, made with the best intentions no doubt, to pass unnoticed. Personally, I am always pleased and prepared, if needs be, to give a reason for whatever I do, and do not in the least mind being called upon to justify any awards which I make conjointly with a brother gardener. This, however, is not the case here; it is only an unintentional accusation of "favour" and want of judgment in those who made their awards conscientiously to the most meritorious exhibits.—H. W. WARD, Longford Castle.

THE PRIMULAS.

(Continued from page 420.)

P. FORSTERI, Stein.—An interesting hybrid between *P. super-minima* × *hirsuta*, Stein. When apparently old plants were first introduced from its native habitat, it appeared nothing more than a strong *P. minima*, but with a little over two years' cultivation the leaves have attained four times their original size. In shape and toothling the leaves are those of *minima*, with the addition of hairs, which it takes from the other parent. Flowers rose-coloured, handsome, and freely produced. Our plants have a western exposure in rich leafy soil mixed with limestone; they are robust and more than ordinarily healthy. It flowers in April and May. Native of Padaster in the Gschnitz Valley, Central Tyrol, where it was found by M. Obrist.

P. GÖBELII, Kerner, which Professor Kerner himself considers simply *P. Auricula* × *viscosa*, while M. Stein in his catalogue of cultivated Primulas writes it *P. super-Auricula* × *viscosa*. In the latter view we concur, as *P. Auricula* clearly predominates in the specimens now before us, which have just been imported from their native habitat, and may be taken as fairly representative of the wild type. In reference to the above species Prof. Kerner says, "On account of the close relation between *P. daonensis*, Leyb., and *P. villosa*, Jacq., it is quite natural that the hybrids raised

from these two species should resemble each other very much. The same characters which distinguish *P. villosa* from *P. daonensis* also distinguish *P. Göbelii* from *P. Portæ* = *P. Auricula* × *daonensis*. The leaves of *P. daonensis* are cuneate, and the abrupt apex set with large teeth of equal length, while the leaves of *P. villosa* are spatulate, obovate, their round apex set with teeth, the middle one of which is much longer than the rest. This character of the leaf of *P. villosa* is distinctly recognisable in those of *P. Göbelii*, and which seems to be the only real likeness to that parent. It is, however, a first-rate garden plant, and the ease with which it may be established on the rockery will soon make it a general favourite. The flowers are of a brownish violet, not unlike some of the garden Auriculas, handsome and freely produced in early spring. It is found growing along with its parents on Steiermark.

P. GLUTINOSA, Wulf.—A Primrose that taxes the ingenuity of most cultivators to flower in a satisfactory manner. It grows fairly well and appears quite healthy, but it will often go for two or three years without showing a single flower. We grow it in an almost perpendicular position between granite and in a soil composed of finely chopped live sphagnum, small pieces of charcoal, peat, leaf soil, and plenty of sharp sand. It should be planted so as to receive only the morning sun, and during the growing season it should be plentifully supplied with water; indeed too much can hardly be given. Care must, however, be taken that the drainage is quite free, as it quickly resents stagnant moisture in however small a degree. The plant grows about 4 or 6 inches in height. The leaves are obovate, glutinous to the touch, and finely serrated for about half their length down on both sides, and thickly covered with tiny glands. Flowers generally in pairs, almost sessile, with bracts much longer than the calyx; sepals blunt, and "sticky" like the leaves. The flowers when fully open are about an inch in diameter, deep lilac, often verging to violet. It flowered with us in April and May, and is a native of the glacial region of the Austrian granitic Alps, where it is found at elevations of 9 to 10,000 feet. It is well figured in Reichenbach's "Flora Germanica."

P. GRACILIS, Stein.—This is given as a cross between *P. cortusoides* × *Sieboldii*, Stein, and which means a cross between *P. cortusoides* and *P. cortusoides* var. *amoena*, Stein using the name *Sieboldii*, Morr., as being the older. It is a well-known plant, being cultivated in English gardens as *P. cortusoides* var. *intermedia*, and although differing little from the type it may find a place for variety's sake where slight forms are noticed.

P. GRANDIS, Trauttr.—For this Stein has coined the new sectional name of *Fredinskya* in honour of the introducer M. Fredinsky of the St. Petersburg Botanic Garden, and he remarks that were it not for the similar inflorescence to be seen in *P. penduliflora* and *P. Palinuri* it could be called a distinct genus, and for the credit of Primulas generally it is almost a pity it was not called something else. It is a robust grower, indeed even more so than *denticulata* and its forms, the leaves attaining enormous proportions, broadly ovate, with an irregularly notched and finely serrated margin. The scapes attain a good height, and carry an abundance of flowers, rose-coloured and curiously formed, but so small in comparison to the strength of the plants as to be disappointing and altogether unworthy a place in any collection unless as a botanical curiosity. Where grown it is best always to plant it out in the open, as it rarely flowers in pots. It flowers with us in May and June. It is a native of the western Caucasian Mountains at elevations of from 6000 to 9500 feet above sea level, and was figured in Regel's "Gartenflora" a few years ago.

P. HEYDEI, Watt.—This belongs to a set of very dwarf creeping or stoloniferous Primroses, natives of the Himalayas, and to which belong *P. reptans*, Hk. fl.; *P. sapphirina*, Hk. fl. and Th.; *P. soldanelloides*, Watt.; *P. muscoides*, Hk. fl., and others, all of which are of the same dwarf nature, only two or three being in cultivation at the present time. *P. Heydei* is a very distinct Primrose, forming little dense tufts, from which short leafy stoloniferous branches are emitted, and which soon take root, forming plants all round the parent, much as is shown in *Saxifraga flagellaris* and in *Semprevivum*. The leaves are small, sparingly mealy beneath, lanceolate in outline, abruptly and coarsely toothed. Flower scapes stoutish, carrying from five to over a dozen pale lilac flowers, each about half an inch in diameter, collected in a loose capitate head, also mealy, as are also the bracts at the base. In winter the leaves die down, leaving little buds, which must not be disturbed during their resting season, a little loose sand being a good protection. It seems most partial to soft sandstone, to which the tiny roots cling with a remarkable tenacity. It flowers about June. Native habitat Western Tibet, at altitudes of from 12,000 to 14,000 feet above sea level, also in Taglang. It requires a shady position.

P. HUTERI, Kerner, = *P. Floerkeana* × *glutinosa*, and also from *P. salisburgensis* × *glutinosa*, Kerner. A very interesting hybrid, and differing but little from *P. glutinosa*. A few of the

principal marks are its leaves not being glutinous, its smaller bracts, and differently coloured flowers. The leaves of *Huteri* are spatulate, with eleven to fifteen broad triangular teeth somewhat thickened at the tips, the middle one being longer than the others. The upper part of the flower-stalk is slightly glutinous, the two or three oblong bracts being broad and almost covering the calyces. The flowers are if anything larger than either the parents, violet-coloured, as in *Viola odorata*. It is thriving well with us in a peaty soil well mixed with small pieces of granite. It is found at various places in the Tyrol, but not over-plentiful in numbers. It flowers during April.

P. INTEGRIFOLIA, L.—Although a comparatively common plant both on the Pyrenees, Northern Italy, &c., where it studs the ground wherever it finds a bare slope in great profusion, it is not often seen in perfection in English gardens. In the majority of places it is generally found dwindling rather than increasing in strength, which we believe in a great measure to be due to insufficiency of moisture and free drainage; for when grown on the flat, well drained, and too rapid evaporation prevented by thickly

ising themselves with us this is no doubt the one, the bed in which we had them growing last year being thick a month or two ago with seedlings. It prefers a free rich soil, where it will increase with great rapidity, apparently unmindful of shade or sunshine. As the leaves mostly die down during the resting season, leaving little buds, these had better be protected from birds, &c., as their scraping often damages them. Where fairly well established they flower all through the summer, and a large patch of their elegant and gracefully drooping sweetly scented flowers is a welcome sight either in the rocky or border. The leaves are 1 to 3 inches long, oval or oblong, slightly cordate at the base, and narrowed into a long wiry stalk. Leaves entire at the margins, rarely crenated, and free of meal. Scapes slender, often about a foot long, terminated with a loose head of from three to six drooping white flowers, about an inch in diameter with deep lobes, and a yellowish or orange eye; bracts linear, surrounding the base of the petioles, reflexed at the base, which is often bifid; calyx tubular, slightly inflated, and prominently three-ribbed. *P. Munroi, Hort.*, is given as a synonym of the above, and as there is a variety in cultivation with lilac or lilac-tinted flowers, and as the name is largely in use in gardens it will perhaps save confusion to preserve the name *Munroi* in a varietal sense, as the type has been described in the *Indian Flora* as having white flowers. It is figured as *Munroi* in the "Botanical Register," 33, t. 15.—D.

PERPETUAL OR SPINACH BEET.

THIS is proving a most valuable vegetable at the present time with us, as were it not for the above variety no Spinach could be had, with us at least, and I doubt if there are not many others in the same field. The Prickly Spinach is very backward owing to the dry weather in late summer and autumn. The seed lay a long time in the ground before germination took place, and when it did it was very slow. The Perpetual is not considered so good flavoured as the ordinary Spinach, but if a little extra attention is paid to the cooking it would go unnoticed at the table by many of the less keen judges. It appears strange that such an easily grown plant should be so little known amongst gardeners, as many have exclaimed when passing through the garden here, "What is that you have there?" when the reply given was Spinach Beet. Here Spinach is most appreciated in early spring and in the autumn and winter. When other choice vegetables are plentiful in summer Spinach is overlooked; this is to our advantage, as the ordinary varieties behave very indifferently on our soil, and I have known the same to be the case in other gardens. It is common in many places to see this vegetable assuming wonderful size, requiring much thinning to do it justice, but it is not so with us.

We have tried artificial manures, lime, salt, wood ashes, soot, horse and cow manures, but all to no purpose in obtaining a luxuriant crop of Spinach. In future it is our intention to sow the round variety for early spring crops, and the Perpetual for autumn and winter supplies. Our seed of the latter variety was sown from the second week in May to the middle of June, and we have been able to pick quantities of leaves for some time; in fact, we could have picked all the summer had the demand rendered it necessary, and we hope to continue it for a long time yet to come. When this variety is grown strongly the stems can be cooked and used like Seakale; but I have only known it used as such in one or two instances, yet I see no reason why it should not become an established rule.—S. B.

CHRYSANTHEMUMS AT THE AQUARIUM.

THERE were many things which gave me an interest in the National Chrysanthemum Society's Show last week. It has, in its constitution and practical working, gone so thoroughly on the lines of the National Rose Society, that, as imitation is the most flattering, I could not but feel flattered that our plans, which I had so large a share in formulating, were considered worthy of adoption, and I was anxious to know how they worked. The Secretary, too, was the son of one whose kind and genial character one always recollects with pleasure, and I was enabled to visit the show in company with one who thoroughly appreciates the flower, and himself grows it largely. All these things made the day a very agreeable one. Mr. Holmes told me that the National Rose plan worked uncommonly well, and that he attributed a good deal of their success to their having adopted it.

I had heard a good deal of the season being late, and that one was not to expect the same excellence or quantity as had been seen in former years, but there was no evidence of falling off in either respect. The entries, I was told, were more numerous than ever, and if flowers are to be had finer and larger than those I saw, it is a marvel, as indeed many of them were; and here let me say I had a very pleasant surprise in seeing the wonderful blooms from my friend Canon Hodgson's garden. I question very much if his boxes of twelve were surpassed by any in the Show, and had a prize been offered for the best box irrespective of numbers, he would have stood a good chance. There was one great drawback. The weather was, to use a term expressed to me, "beastly." A thick fog was over everything, worse, I believe, on Thursday than on Wednesday. The Aquarium is a bad place for an exhibition, and on such a day it was very bad. However, we had an opportunity of seeing it before the fog was very thick, and although it dulled the colours, yet we got a pretty good idea of them.

Fig. 71.—*Primula involucrata* (*P. Munroi*).

strewing the ground with pebbles, it flowers with great freedom. Though its increase is anything but rapid, it is in excellent health, which is one step towards it. A dwarf-growing plant, nestling close to the ground, and rarely with anything of a stem; leaves crowded in little rosettes, oblong elliptic, slightly dilated at the base, quite entire, and having a narrow cartilaginous margin in some cases and—notably in plants from the Albula Pass Engadine—with a few hairs; whitish underneath, and dull, not shining as in *spectabilis* on the upper surface. Scapes short, not more than an inch, bearing two or three lilac-purple flowers, broader than the length of the tube; calyx of ovate blunt sepals, surpassed by the narrow bracts. It was first introduced by Baron Sigismund von Zoiss of Laybach, and flowered in 1792 by Mr. Loddiges. It flowers in April. Lehman has figured a remarkable variety with toothed leaves, which we have not seen in cultivation. Syn., *P. Candolleana, Rich.*

P. INVOLUCRATA, Wall (fig. 71, reduced from plate 15, vol. xxxiii. of the "Botanical Register").—One of the most charming, and perhaps the commonest in gardens, of all the Himalayan Primroses. It was, we believe, first collected by Captain Munro at an altitude of about 12,000 feet above sea level, and owing to its high elevation perfectly hardy with us even in severe winters. It ripens seed with great freedom, and may be raised in almost any quantity, and if there is a possibility of any of the Himalayan Primulas natural-

Going out of the ordinary run of stages and boxes, the stands set up by Mr. Cannell of Swanley formed a notable and novel feature. The boxes were arranged with considerable taste, each variety being represented by about three blooms arranged in a triangle with fern and other foliage, on a bed of green moss. This was very attractive, and suggested to one whether boxes of trebles, as in the case of Roses, would not be a pleasing innovation. To those who do not grow the Chrysanthemum for exhibition this was a pleasing and novel exhibit.

Unquestionably the great advance has been in the Japanese class. Very few new incurved varieties are to be seen, and nearly all of them are sports from older varieties. The chief interest, as far as the general public is concerned, is centred in them also, and for one who stops to admire the incurved flowers there are twenty who admire the quaint forms and curious colourings of the "Japs," as I heard them familiarly called by some eager exhibitor. Amongst them, I think the most taking flower was Jeanne Delaux. It is the deepest in colour of all, and there was hardly a stand in which it did not come out grandly, and affording by its high colour a striking contrast to the other flowers. It was also shown under the name of F. Davis, there not being the slightest difference in the two flowers. Another very remarkable flower was the large Japanese-Anemone flower figured in last week's Journal—Sœur Dorothee Souille, more remarkable, I think, than beautiful. The same may be said of Fabian de Mediana, but the newer flower is more regular in the centre than it. These flowers form an entirely fresh break, and there is no knowing to what hybridisers may bring the flower, as it seems to offer such facility for hybridising, and to cross readily with the other section. Amongst other flowers in this section, Beauté des Jardins, very brilliant in colouring; Belle Alliance, with long drooping petals; Brise du Matin, an enormous flower, rose and white; L'Or du France, a very beautiful and brilliant flower, the petals hang down most gracefully, golden yellow, with brick-red markings, the reverse of petals dark violet. It is very distinct, and one that is sure to please most people. Madame Clemence Audiguier was another flower that was shown in grand style and is one of the largest and finest flowers in growth. Thunberg, Soliel Levant, L'Or du France, Madame Levin, Fabian de Mediana, and Fernand Feral were all much admired. I have not mentioned the incurved, as we met with but few that are not well known, Lord Alcester and Lord Wolseley being amongst the best.

More interesting to me were the plants. We know to what lengths the dressing of these flowers is carried, so much so that I fear very much the success of the exhibitor depends as much upon the dresser as it does in Picotees and Carnations. In some instances a wide circle is placed underneath the drooping Japanese varieties so as to give them greater size. The Society is endeavouring to do away with this as much as possible, and for this purpose offered a prize for a support which might prevent the flowers being pushed up in the centre; and although the support patented by my neighbour, Mr. Foster of Ashford, has much merit, it was considered as not coming within the object of the Society by not preventing this. In the plants exhibited there is not so much room for this, nor are the flowers so monstrous as those which are exhibited as cut blooms. There were amongst the groups exhibited many which were the very model of good cultivation, the plants well clothed down to the pot, no sign of mildew, and each carrying its full share of bloom equally arranged all over the plants. The groups of Mr. Stevens and Mr. Davis were very fine, but it was amongst the class for nine varieties that I think the best were to be found. They were about 3 feet high and 3 through, and there was a plant of George Glenny amongst them which seemed to me the very perfection of what a pot plant ought to be, far more interesting than the enormous specimens 6 feet through which were set up. Even with plants such as these it would require a considerable amount of glass to grow them, and while we small people look on with wonder, we feel that we must be contented with doing things on a much smaller scale; still as proofs of what skill and intelligence can effect these plants were most interesting.

Very rightly there were few certificates awarded. The rush of new Japanese varieties is very great, and the quantity of varieties, and now that the continental raisers have gone into it, we may expect the list to be added to every year. The Tweedledums and Tweedledees will be numerous, and therefore great caution ought to be observed in recommending new varieties.

I have said nothing about the other exhibits, fruit, vegetables, &c., and have only given these sketchy impressions of the Chrysanthemums, a flower that, more than any other, accommodates itself to all situations and rewards the most ordinary care, while it generously and gratefully accords its fullest favours to those who treat it well.—D., Deal.

NOTES ON HARDY FRUIT.

American Cut-leaved Blackberry.—As showing the value of this useful Blackberry, Messrs. Cheal & Sons of Crawley have exhibited at various shows during the present and past seasons sprays of ripe fruit as cut from the plant, to indicate its large size and productiveness. It deserves all the praise they have bestowed on it. Whilst on a visit to their nurseries I was shown the plants the sprays of fruit were cut from; they are growing behind the north side of a wooden fence, and were literally covered with the remains of fruiting clusters.

Good Apples.—The following good Apples are highly recommended by Messrs. Cheal, and are considered by them to be deserving of increased cultivation:—Egremont Russet, Lane's Prince Albert, Lady Henniker, New Hawthornden, and White Melrose.

Anent the question of growing too many varieties, it would be well if

those who advance this notion would name two or three varieties, so that we should know what to grow. Now that hardy fruit culture is extending we may be able to ascertain what are really first-class varieties for all seasons and purposes after the lapse of a few years, as it is quite evident that many varieties that have been almost in obscurity, or have not had a fair trial, are now being planted largely in different parts of the country, and will have an opportunity of proving their worth similar to the Ribston Pippin, Cox's Orange Pippin, Blenheim Pippin, Dumelow's Seedling, Keswick Codlin, Lord Suffield, and King of the Pippins.

Lifting Fruit Trees.—This subject cannot be too prominently brought before the gardening public, as it is an excellent practice. It is an old saying and a true one, that "A proper training in youth is a forerunner of good in after years." If young fruit trees were carefully lifted and replanted periodically in the first few years of their existence, we should not hear of so many cases of canker and unfruitfulness as are now recorded. When young trees are replanted carefully and early in the season it does not affect their fruiting in the least, and if a surface dressing could be given every season afterwards with farmyard manure, very little attention would be required as regards root-pruning.—A. YOUNG.

WINTER PROTECTION FOR TENDER PLANTS.

THE sharp frosts we had a few days since will make many people anxious to have everything secure in case severe weather sets in shortly. Many beautiful plants are lost yearly which might have been saved if only very slightly protected. I am speaking more particularly of those growing in borders, &c., as the same plants if growing in pots are easily removed to cold pits and made safe; but it is impossible to see the full beauty of many plants when grown in pots, and hence planting out becomes almost a necessity. Take, for instance, *Aloysia citriodora*, Myrtles, Tea Roses, the smaller varieties of Fuchsia, such as *gracilis*, *globosa*, *corallina*, &c., the beautiful Coral Plant *Erythrina crista-galli*, *Salvias patens* and *fulgens*, and many others, which are not seen to perfection unless growing freely. It is not always advisable to lift these from their positions. The question is then, Which is the best way to preserve them from severe frost? For those that can be cut down near to the surface of the ground with advantage, I have found nothing to equal coal ashes, placed from 4 to 6 inches thick all over the crowns, and wide enough to cover the principal roots. Next to this, perhaps, comes sawdust in efficiency, and it has also the advantage of checking the ravages of slugs in the spring more than the former substance, as from its lighter nature it does not get beaten down so easily by heavy rains, but as a protection from frost only it is not so good. Then we have cocoa-nut fibre, rough leaf soil, short litter, and many others, amongst which I should think cork dust would prove one of the most useful, although I have never had the chance to try it.

So much for protection of the roots; but besides this it is in many instances well to try and preserve the tops also, and even if this is immaterial they should be left on until frosty weather is over, as if cut down, as in Fuchsias, for instance, when green in the autumn, the frost will work down the pith much further than it would otherwise do. For this purpose straw drawn out straight and placed in as sharp a conical form as possible is often very handy in the case of beds of plants. A good covering of quite dry Beech or Oak leaves, shaken among the tops and made as waterproof as possible with straw or mats, is very useful for deciduous plants. Dry bracken is also a very useful protection, especially for standard Tea Roses, &c., a handful being tied on to cover the junction of stock and scion, and as much of the head as possible. To get this in its best form it should be cut previously to losing its green colour in the autumn. Branches of thick evergreens, such as Spruce, Yew, Portugal Laurel, &c., are also very efficient.

I have seen a sample of a new material for protecting, which appears just what is wanted for some purposes; it is called dressed scrim, and looks like canvas dipped in Stockholm tar. I am told it was brought out at the suggestion of Mr. Rust of Eridge Castle. It appears likely to excel anything we have as a covering for pits and frames, but is not generally known in the trade. I believe it is made in Cornwall.—W. H. DIVERS, Ketton Hall.

VEGETABLES AND THE FROST.

WITH us the winter has set in earlier than I have previously experienced. From November 14th to 17th a high wind has blown from the north-east, and as we have had from 6° to 10° of frost nightly, it has caught vegetation very keenly. Those who look ahead will always be prepared for severe weather any time after November begins, but as mild autumns have not been uncommon of late years, a severe one may find many unprepared. The best way to deal with vegetables is to protect them from the first, and not allow them to be exposed for a few nights to the frost, and then try to remedy the injury. Cauliflower will soon suffer. If the smallest heads are browned by the frost it is all over with them. The only way is to cut every one that is ready for the table on the first frosty night, and go over the others daily to break some of the leaves half through, and turn them down over the heads. Another way is to gather all the leaves together over the top of the heart, and bind them there with a piece of matting or willow.

Early greens are the hardiest of all. They do not require

any attention, neither do Leeks. Turnips which are not fully developed should have a quantity of soil from each side drawn up over the bulbs before the soil becomes frozen. Savoys droop in the time of frost, but they are rarely injured, and the frost generally makes them sweeter. Brussels Sprouts are not easily injured, although frost does not benefit them. The leaves are sometimes taken almost all off with the alleged object of exposing the sprouts to the sun, but they develop as well without this, and the side leaves are of great use in protecting the sprouts during severe frost. Cabbages droop as much as anything with the frost, but they soon recover after a thaw, though in the case of a very severe frost young plants are always benefited by having the earth drawn up to the stems. Lettuces and Endive of a large size are easily injured, and should either be taken up and packed closely together in frames, or be covered where they are growing with a thick layer of straw or fern. The lifting plan is the best. Young plants for a spring supply are hardier, and they will bear much frost without being injured. When they require protection they should be covered where they are growing, and not lifted.

Celery is easily injured, and when once it is softened by the frost it will never come right again. When the last earthing-up has been given, some fine ashes are put round the stems to the depth of 4 inches, and then 12° of frost will not injure it. The ashes lie close to the growths, and they keep out frost so much better than soil that they ought to be generally used for protection in winter. Sawdust is also good for this purpose, as the frost will hardly penetrate it. Asparagus, Seakale, and Rhubarb roots are not easily injured, but severe frost certainly does not benefit them, and they should all have a top-dressing of manure before the frost hardens the ground. Globe Artichokes shrivel more quickly than any vegetable, and the only way to save them is to place a comfortable collar of long manure round them before the temperature falls to 30°. The majority of herbs are quite hardy, and although we spread manure over the surface of the Mint, Tarragon, &c., in winter, it is more to strengthen the growths than to prevent injury from frost. Parsley is very hardy, but shrivels with a few degrees of frost, and it is an advantage to treat it in the same way as the Lettuce. When Parsley is plentiful in summer large quantities should be gathered and dried for winter use, as for everything, excepting garnishing, it is just as useful dry as green. The China Rose Radish will bear much frost, and we only dig and store them when we see that the ground is becoming very hard. Spinach shrivels to a great extent, but when thaw comes it expands again, and if the leaves chance to be killed the roots will always produce fresh growth in spring.—A KITCHEN GARDENER.

PLANT-GROUPING FOR EFFECT.

(Continued from page 450.)

WE may now turn to flowering plants, which are, perhaps, of greater variety even than foliage plants, yet, generally speaking, a few form a special feature, and are more effective than a great number of different kinds of plants. For instance, three to five plants of *Anthurium Schertzerianum* or *A. Andreanum* would at once overbalance a vast number of other flowering plants. One point to be guarded against is not to use too freely plants that happen to be in season, such, for instance, at spring shows, as *Spiræa japonica* or bulbous flowering plants, or in autumn of *Vallota purpurea*. Rather endeavour to have choice or out-of-season plants, therefore forethought is needed in bringing forward or retarding such plants. In spring groups small Azaleas may be usefully employed, and perhaps two or three small well-bloomed Camellias, *Dielytra spectabilis* sparingly, early Pelargoniums of the Regal section, while if small plants of *Clerodendron Balfourianum* can be had in bloom they will help considerably.

Summer groups must demand most attention. It often happens that some gardeners during those months are very heavily handicapped compared with others, and hence the need of either giving the object special attention or staying at home, as not many employers care for second or third prizes any more than gardeners themselves; and although a gardener may be at a discount in point of convenience, culture and taste may do much to make up the difference. In this way, in an establishment where the gardener does the major part of the inside work himself, he gains something upon the gardener, who having more outside charges, has to leave much in charge of others, who it cannot be expected, as a rule, to be so much interested as himself.

Turning to the plants most useful at this season, *Anthuriums* should receive attention, but I may remark here that, in my opinion, exhibiting plants in pairs must be carefully avoided. It may not matter in the case of some minor plants, but when they are striking care must be exercised. As a distinct change of tint nothing is more effective than a number of *Statice Butcheri* or *S. profusa*, for not having too much foliage they may be arranged quite level with the groundwork, while the spikes will not crowd other relieving plants; in fact, to be really effective there should be three or four separate heights all standing clear of each other. *Ixoras* in variety are indispensable for rich yet quiet tone. *Ericas* are valuable

in every way, also such Orchids as can easily be worked in without crowding the groundwork. *Kalosanthes*, with a few fresh heads, follow among light Palms. *Bougainvilleas*, carrying a few spikes in, say, 6 or 7 inch pots, some 3 feet high, give good relief. In the back part *Clerodendron Balfourianum*, as mentioned before, is extremely valuable.

A very telling plant, rarely seen to advantage in groups, is *Clerodendron fallax*; these grown from seed sown almost any time during the year make fine plants. Plants one year old, cut down in January in heat, soon make good plants, and continue blooming from May to November, and nothing is more striking. A few *Celosia pyramidalis* may be employed if very choice in strain; a few plants of *Lilium auratum* and *speciosum* render the outside more bold, while *L. Harrisii* is invaluable; Cockscombs also, such as the Glasgow Dwarf strain, about half grown, placed crosswise, a few are a good change; Tuberous *Begonias*, too, are useful when they travel safely, as also are *Gloxinias* when of a good strain and fresh. Regarding this point, local exhibitors have some advantage over strangers, as little choice additions can be made at home, whereas exhibitors from a distance would not venture them. Ornamental Grasses and *Rhodanthe Manglesii* are useful; another effective feature being produced by *Zinnia elegans* from seed sown about Easter in a warm frame, and a few of each colour placed into 4 or 5 inch pots will make a fine display early in July, and having little foliage may be arranged where almost any other plant would be crowded, and they impart a rich tint that is not to be had in any other flower. Two or three single spikes of *Eucharis amazonica* on plants in small pots, or a spike of *Pancratium* have a good effect at any season. Should it be a table of plants, as at some shows, a certain distance from the floor, *Isolepis gracilis*, *Ficus repens*, more straggling *Panicum*, *Tradescantia*, or a few small plants of *Cissus discolor*, may be required in addition for groups arranged on the greensward.

I may repeat an expression which I have often used, that unless a gardener is able to tastefully arrange a group of good plants he is not competent to superintend laying out and effectively furnishing lawns and shrubberies. Some may differ from me on this head, but such is my experience.—LATHYRUS.

WE are informed on good authority that SIR JOSEPH D. HOOKER has resigned his office of Director of the Royal Gardens, Kew, which he has held since 1865 with so much credit to himself and advantage to the public service. Sir Joseph succeeded his father, Sir William Jackson Hooker, who had administered the office since 1841. Sir Joseph's resignation will take effect from Monday, the 30th inst. No successor has yet been appointed.

— A MOUNTED photograph of the HULL CHRYSANTHEMUM CHALLENGE VASE has been sent to us. It is, we are informed, the work of a lady amateur (Miss Jameson), a sister of the energetic Secretary of the Hull Chrysanthemum Society. We congratulate Miss Jameson on her admirable production, which is "quite a work of art."

— WE learn that LADY LOUISA ROLLE OF BICTON, DEVONSHIRE, died on the 20th inst., in her ninety-first year. Bicton has long been a celebrated garden, and Lady Rolle for many years was an ardent patroness of horticulture, giving especial attention to the formation of a fine collection of Conifers.

— THE Rev. G. Henslow has for some time been engaged in experiments and observations on the INFLUENCE OF LIGHT ON TRANSPIRATION IN PLANTS, and it is expected that he will communicate the principal results he has obtained at the meeting of the Linnean Society on December 3rd.

— WE learn that three members of the GHENT HORTICULTURAL SOCIETY have been appointed Chevaliers de l'Ordre de Léopold—namely, MM. Ad. d'Haene, C. Spae-Vander Meulen, and A. Peeters. A banquet in honour of these gentlemen takes place to-day (Thursday) in the Hotel de la Poste, Ghent.

— MR. A. YOUNG sends the following note on CORDON PEAR TREES AT WORTH PARK, CRAWLEY:—"In the kitchen garden at the above place is a wall upwards of 430 feet in length planted with cordons, and I have never seen trees look healthier or more promising, and they are creditable alike to Mr. Glyn, the gardener, and to Messrs. Cheal and Sons, from whom the trees were purchased. The varieties are a selection of the best and Bergamotte d'Esperen is wonderfully fine."

— MR. WILLIAM H. BANNISTER, The Gardens, Cote House, Bristol, informs us that the Committee at the Bath Show awarded him an equal first prize for a collection of Pears.

— "T. W. S." writes that the ORCHIDS AT MESSRS. J. LAING AND CO.'S NURSERY now occupy several new houses, a commendable feature of which is the use of corrugated iron by this firm in preference to slate or wood staging. It is more durable, as well as, when covered with shell shingle, retaining a greater amount of moisture. The Cattleyas are in excellent health, among which we noted some fine examples of *C. Lawrenceana*. *Vanda Sanderiana* is also doing well here grown in baskets suspended from the roof. There is also a large healthy example of the somewhat scarce and rare *Sobralia viridifolia*. Many species of *Dendrobiums*, *Lælias*, and *Cypripediums* were in flower.

— AS a conservatory plant, *CHRYSANTHEMUM MADemoiselle Lacroix*, or *LA PURETÉ*, is unsurpassed amongst the white-flowering varieties, and those who have seen it at Mr. B. S. Williams' Nursery will be able to form an adequate idea of its value in this respect. It was obtained last year under the name of "*Madame*" *Lacroix*; but though the blooms differ to some extent on freely grown and undisbudded plants, from those grown specially for exhibition it is apparently the same variety. The florets are shorter on the conservatory plants, slightly fluted or twisted, pure white, fully justifying what appears to be its true name, *La Pureté*, as there is only a slight yellow tinge in the centre of the expanding bloom. The variety is extremely floriferous, and continued in good condition late in January last year. For general decoration or cutting it proves invaluable.

— IN the same nursery there are several ORCHIDS IN FLOWER at the present time, including the following:—*Cypripedium insigne* Chantini, very fine, the dorsal sepal $2\frac{1}{2}$ inches in diameter, with a broad white margin and purple spots. *Calanthes Veitchii* and *vestita* add their attractions, some remarkably strong spikes of the former being notable. *Oncidium tigrinum* furnishes abundant panicles of bright golden flowers. *Vanda suavis* tricolor and the wonderfully distinct *Sanderiana* are flowering well, the last named being represented by a light-coloured pretty variety, quite different from any we have previously seen. *Dendrobium superbiens*, which some complain is a difficult plant to grow, is most successful at Holloway, there being quite a pretty display of its deep purplish flowers. It is one of the most continuous-blooming species in cultivation, some having been had for three months in attractive condition. *Zygopetalums* and several other plants are also attractive, and the general collection is in most satisfactory condition.

— ONE little Orchid deserves special notice—namely, the BRAZILIAN HAWTHORN, as *Burlingtonia fragrans* is sometimes popularly designated in reference to its delicious perfume. It is capitally adapted for culture in small pots to suspend from the roof of an Orchid house, as the racemes of pure white flowers are pendulous, drooping round the pot or pan, and attaining a length of 8 to 12 inches. Its usual time of flowering is in the spring, but several plants are now bearing flowers which frequently last for a month in good condition.

— MR. A. R. COX, The Gardens, Elm Hall, Wavertree, Liverpool, desires us to state that "At the HUDDERSFIELD CHRYSANTHEMUM SHOW recently he was awarded first prizes for both forty-eight and twenty-four cut blooms, with two special prizes for the best incurved and best Japanese in the Show, with Mr. Bunn and Boule d'Or respectively.

— A DURHAM correspondent writes:—"Messrs. Clark Bros., nurserymen, Moorhouse Nursery, North Shields, have an excellent sport from CARNATION SOUVENIR DE LA MALMAISON. It is of the same type and habit, and the colour is a most delicate rose. It is already quite a favourite amongst north-country ladies. It promises to be a great acquisition."

— A CORRESPONDENT sends the following note:—Mr. J. MacMichael's annual SHOW OF CHRYSANTHEMUMS AT SPIKE HOUSE, HAMMERSMITH, has this year included many specimens of rare beauty. Some of the finest were secured by having them placed under glass before the rough weather set in. The following are a few of the most noteworthy:—The Maid of Athens; Cullingfordi, bright crimson, flowers very large and attractive; Beauté des Jardins, deep crimson-toned with violet; Belle Alliance, deep red, shaded maroon; Blanche Neige, pure white, very

large; Etoile du Midi, orange red; Jeanne Delaux, fine large flower, very long florets, dark crimson; Frizon, bright canary yellow; La Géante de Valence, long tubular florets, shaded with violet; L'Alsace, deep reddish violet, dotted with white; Mdle. Lacroix, sulphur white, extra fine; Mdle. Antoinette Brunel, pale rose suffused with white; William Robinson, bright sulphur yellow; Madame de Sevin, deep rosy lilac, very effective. The Show has been one of the best amateur displays of the season.

— WE have received fruits of the new CRAB JOHN DOWNIE, raised by Mr. E. Holmes (formerly of the old firm of Fisher & Holmes), at his Whittington Nurseries, Lichfield. The fruits are of the size and shape of large nutmegs, and borne in great profusion on the branches. They are bright red in colour, and in taste and texture resemble the Siberian Crab. John Downie Crab promises to be an acquisition for shrubberies, pleasure grounds, and ornamental plantations.

— A CORRESPONDENT informs us that a bunch of GROS GUILLAUME GRAPES WEIGHING 20 lbs. has recently been sent by Mr. McKenna, gardener to the Chief Secretary for Ireland, at his official residence in the Phoenix Park, Dublin. The bunch measures 24 inches across the shoulders and is 27 inches long. It is described as a model in shape, and the berries large, regular, and perfectly finished. Though not the largest, this is considered by judges competent to form an opinion on the subject the most meritorious bunch of this variety that has been grown, and for which, we are informed, a silver medal was granted at the late Dublin Show. The Vine that has produced this splendid bunch was one of several others that were raised from eyes three years ago. They were cut down after the first year's growth, made and matured grand canes last year that were left 7 or 8 feet long, and have this year produced a splendid crop, some other bunches weighing from 12 lbs. to 15 lbs. Mr. McKenna is to be congratulated on his notable achievement.

— THE following SIMPLE METHOD OF GROWING TUBEROSES is, we are told, practised by Mr. Bell at Strathfieldsaye. He keeps them in paper bags in a cool place till May, then plants them in good soil in the garden. There they grow steadily and sturdily, producing stout flower spikes by the autumn, when the plants are taken up and potted. Plants thus treated are now flowering splendidly, fifteen to twenty blooms on a stem, and will afford a valuable supply for cutting for a long period.

— THE EFFECT OF SOIL ON PEARS was well exemplified by examples of fruit of Beurré Diel sent to the Lincoln Show (which could only be briefly reported last week) by Mr. G. Picker, gardener to A. S. L. Melville, Esq., of Branston Hall. Fruit gathered from a tree with its roots in cold inert subsoil was so pitted and specked as to render the sample worthless; fruit from a similar tree, but with its roots in good soil near the surface, was perfectly clear, and specimens from a wall tree that had been lifted last year and the roots placed in good soil were also quite clear and larger than the others, shelter having had a beneficial effect as well as good soil. If what is bad were occasionally exhibited as well as what is good, and the cause of the difference indicated, horticultural shows would be instructive as well as attractive. A vote of thanks was accorded to Mr. Picker for his interesting contribution.

— MR. B. COWAN writes:—"R. S. Donkin, Esq., North Shields, has lately erected a range of glass 336 feet long. The first portion is divided into a splendid WINTER AND SUB-TROPICAL GARDEN. The rockwork in this department is most natural, the water falling over cascades with sufficient force to make it dance as if it were amongst natural boulders. Palms, Tree Ferns, and Magnolias are quite at home, while from the roof hang Tacsonias insignis, Van Volxemi, Passion Flowers of sorts, all forming and creating with the waterfalls a most pleasing sub-tropical aspect. The plant houses contain many choice varieties of Crotons, all in excellent condition. We noticed Clerodendron splendens trained to a pillar, very beautiful in flower at present, also Jasminum gracillimum. The grounds are small, but they are well laid out and tastefully kept. There is a splendid rockery, with an excellent collection of Rhododendrons; also Thujopsis dolabrata and Cotoneaster microphylla, all doing well within a mile from the sea. The houses and grounds are in excellent order, and reflect credit on Mr. Metcalfe, the gardener."

— FRAGRANT FLOWERS.—The perfume manufacturers of Nice and Cannes crush 154,000 lbs. of Orange blossoms, 13,200 lbs. of Acacia flowers, 154,000 lbs. of Rose petals, 35,200 lbs. of Jasmine blossoms.

22,000 lbs. of Violets, 8,800 lbs. of Tuberoses, and a relatively large amount of Spanish Lilacs, Rosemary, Mint, Lime and Lemon blossoms every year.

HOW TO MAKE POTASH.

BARON FERD. VON MUELLER, K.C.M.G., of Victoria, writes as follows how to make potash. The wood, bark, branches, and foliage are burnt in pits sunk 3 feet or 4 feet in the ground; the incineration is continued until the pit is almost filled with ashes. Young branches and leaves are usually much richer in potash than the stem-wood, hence they should not be rejected. The ashes thus obtained are placed in tubs or casks on straw over a false bottom. Cold water, in moderate quantities, is poured over the ashes, and the first strong potash liquid removed for evaporation in flat iron vessels, while the weaker fluid is used for the lixiviation of fresh ashes. While the evaporation proceeds, fresh portions of strong liquid are added until the concentrated boiling fluid assumes a rather thick consistence. At last, with mild heat and final constant stirring, the whole is evaporated to dryness. This dried mass represents crude potash, more or less impure, according to the nature of the wood employed. A final heating in rough furnaces is needed to expel sulphur combinations, water, and empyreumatic substances; also to decompose colouring principles. Thus pearlash is obtained. Pure carbonate of potassa in crude potash varies from 40 to 80 per cent. Experiments, so far as they were instituted in the laboratory, have given the following approximate result with respect to the contents of potash in some of our most common trees:—The woods of the Casuarinas, or She-Oaks, as well as that of the black or silver Wattle, are somewhat richer than the wood of the British Oak, but far richer than the ordinary Pine woods. The stems of the Victorian Blue Gum and the so-called Swamp Tea-tree (*Melaleuca ericifolia*) yield about as much potash as European Beech. The foliage of the Blue Gum proved particularly rich in this alkali, and as it is heavy and easily collected at the sawmills, it might be turned there to auxiliary profitable account, and, indeed, in many other spots of the ranges. In the Queensland coast country the Mangrove could be made to yield potash in immense quantities, as it is richer in this alkali than almost any other native tree or shrub; and even if the Mangrove were not used for the manufacture of potash, the Ash being rich in this valuable fertiliser, could be easily and economically applied for manurial purposes. Of course British woodmen are aware that it is hopeless to compete with the extensive mineral deposits in Germany, whence most of the potash of commerce is now made.—(*Forestry*.)

CHRYSANTHEMUM LA PURETE AND MDLLE. LACROIX.

THE above appear to me similar in every respect, with the exception that *La Pureté* has much broader florets, and does not twist so much as *Mdlle. Lacroix*. A good bloom of *La Pureté* resembles a fully expanded flower of *Elaine*. The habit, height, and time of flowering are the same in both. I am inclined to believe *La Pureté* superior to *Mdlle. Lacroix*, as the latter becomes fluted with age. According to Mr. Lewis Castle they were both sent out or raised in 1880. I have grown and flowered *Mdlle. Lacroix* four years, but *La Pureté* only made its *débüt* in England in 1884.

There are two more Japanese Chrysanthemums that appear to me identical so far as my experience goes—namely, *Val d'Andorre* and *Gaillardia*, *Souvenir d'Haarlem* and *Roseum superbum*. The two latter were raised and sent out by J. Delaux, the latter in 1884, and the former in 1885. So far as I am able to discern, it is a distinction without a difference.—**ROBT. OWEN**, *The Floral Nurseries, Maidenhead*.

THE CELERY CROP IN YORKSHIRE.

In page 404, November 5th, of your Journal, your correspondent, "B., *Hants*," wishes to know how the Celery crops are in other gardens. I send you two roots of a variety grown and raised in this neighbourhood called Clayworth Pink. They are not pickle roots, merely taken from a dray-load at the station. We have been growing 400 acres of the same variety within a radius of ten miles of Bawtry. It is quite a harvest with the farmers and cottagers; they are sending about 200 tons per week away to different markets from the following stations—Bawtry, Ranskill, Retford, Beckingham, and Misterton. It is grown in patches of from one rood to forty acres. It is quite a sight to see the growers commence taking up the roots in September. The land is chiefly peat or bog, very little use for other purposes, and five years ago we had not thirty acres in the same district.

The crops are very good, the prices for late crop £35 to £40 per acre; early crop £45 to £60 per acre. In the parish of Everton alone there are 120 acres this season. No Celery fly this season.—**C. M. BREWIN**.

[The specimens are solid, heavy, and remarkably well-grown samples. What is the cost of production?]

CHRYSANTHEMUM NOTES.

CHRYSANTHEMUMS AT MESSRS. LAING & CO.'S.—The show of Chrysanthemums in the large show house in Messrs. J. Laing & Co.'s, Stanstead Nurseries, Forest Hill, is a very attractive one just now. It is not, however, quite as good as last year, owing to the greater part of the plants having had their buds injured by the frosts. Of the new

Japanese varieties in flower, *Mons. Ghys* is a very fine flower, of a gold and silvery white colour; *La France*, rich carmine with white centre, very fine; *Jupiter*, dark crimson and red, especially fine, and *Mons. Ivon*, a beautiful creamy white tipped with gold. In addition to these novelties all the best and latest sterling varieties are grown in quantity, and not a few of their own seedlings are of a very promising character.

CHRYSANTHEMUMS AT PARKFIELD, LEE.—So popular has the queen of autumn flowers become that it is scarcely possible to find a garden where its beautiful merits are not recognised and a prominent place assigned to its culture. It is certain that no other class of plants have yet been brought forward by our enterprising horticulturists to take their place in doing the lion's share of decorating the conservatories and greenhouses, and supplying cut flowers for personal and house decoration, and last, but not least, filling hundreds of exhibition tables throughout the country at a time when other flowers are scarce. The more the merits of this beautiful autumn flower are known the greater does its popularity deservedly become, with the natural result—an increase in the number of growers and the greater the excellence of culture attained. Every grower, be he amateur or professional, who excels in the culture of this charming flower deserves to have his success recorded in the pages of the horticultural press, to serve as a stimulus to others to attain to similar excellence of culture. Well worthy of such recognition is the well-grown collection of varieties in the garden of F. Hatchett, Esq., Parkfield, Grove Park, Lee, whose able and enthusiastic gardener, Mr. J. Sharpe, is quite an expert in their culture, and a very successful exhibitor at many of the leading shows. The collection grown here numbers over 400 varieties, and owing to the limited amount of glass at the disposal of the gardener it is a wonder how so many plants find house room. The plants are packed as close together as possible, and from the giant, 9 and 10 feet high plants, of *Madame Clemence Audiguier* to the dwarf *Pompons*, there are banks of colour of dazzling and varied brightness. The foliage was of unusually thick texture, and of a dark, healthy, vivid green, whilst the flowers of such capital varieties as *Queen of England*, *Père Delaux*, and *Criterion* were very fine, being large and well formed, with good broad petals.

Amongst the general collection of Japanese and incurved varieties those most conspicuous for size, richness of colour, and good culture were *Madame C. Audiguier*, *La Nympe*, *Comte de Germiny*, *Criterion*, *Elaine*, *Fair Maid of Guernsey*, *Boule d'Or*, *L'Incomparable*, &c., among Japanese; and *Queen of England*, *Empress of India*, *Lord Wolseley*, *Mabel Ward*, *Mrs. W. Shipman*, *Refugeance*, *Nel Desperandum*, &c., among the incurved section. No useful purpose will be served in occupying space with a list of names, as the best varieties are being constantly brought under the notice of readers in the reports of shows now being held in various parts of the country. Mr. Hatchett is greatly interested in the Chrysanthemum, and gives every encouragement to his gardener to attain success in its culture, and the well-grown and flowered plants reflect great credit on both employer and gardener.—**T. W. S.**

ROYAL METEOROLOGICAL SOCIETY.

THE opening meeting of the session was held on Wednesday evening, the 18th inst., at the Institution of Civil Engineers, 25, Great George Street. Mr. R. H. Scott, F.R.S., President, in the chair.

Messrs. T. K. H. Clunn, R. S. Davies, B.A., H. C. Fox, M.R.C.S., W. E. Jackson, J. Richardson, M.Inst.C.E., F.G.S.; A. L. Hotch, and C. Todd, C.M.G., were elected Fellows of the Society.

The following papers were read:—

1. "The Helm Wind of August 19th, 1885," by William Marriot, F.R.Met.Soc. This wind is peculiar to the Cross Fell range, Cumberland, and is quite local, but very destructive. The chief features of the phenomenon are the following:—On certain occasions when the wind is from some easterly point the helm suddenly forms. At first a heavy bank of cloud rests along the Cross Fell range at times reaching some distance down the western slopes, and at others hovering about the summit; then at a distance of one or two miles from the foot of the Fell there appears a roll of cloud suspended in mid-air and parallel with the helm cloud—this is the helm bar. A cold wind rushes down the sides of the Fell and blows violently till it reaches a spot nearly underneath the helm bar, where it suddenly ceases. The space between the helm cloud and the bar is usually quite clear, blue sky being visible; at times, however, small portions of thin vaporous clouds are seen travelling from the helm cloud to the bar. The bar does not appear to extend further west than the river Eden. The author visited the district in August last, and was fortunate enough to witness a slight helm. He gives a detailed account of what he experienced, and also his observations on the temperature of the air at the summit and base of Cross Fell, the direction and force of the wind, the movement of the clouds, &c.

2. "The Typhoon Origin of the Weather over the British Isles during the second half of October, 1882," by Henry Harries. The author shows, by means of daily charts, that a typhoon which originated near the Philippine Islands on September 27th passed over Japan and the Aleutian Archipelago, entering the United States on October 10th. Crossing the Rocky Mountain range it proceeded through the Northern States and Canada to Labrador and Davis Strait. In the Atlantic it was joined on the 18th by another disturbance which had come up from the Atlantic tropics, the junction of the two being followed by a cessation of progressive movement from the 19th to the 25th. During this period the severe gale which passed along our southern counties on the morning of the 24th was formed, its sudden arrival upsetting the Meteorological Office forecasts of the previous night. Observations are quoted, showing that it would have been impossible for the department to have been aware of its existence before about 3 A.M. of the 24th. Following in the wake of this storm, the parent cyclone reached the French coast on the 27th; its advent being marked, as in Japan and America, by violent gales and extensive floods over the whole of Western and Central Europe; and

Algeria. The village of Grindelwald was destroyed, and in the Austrian Tyrol the damage caused by floods reached at least two millions sterling. Passing through France and the Netherlands the disturbance showed signs of exhaustion, and on November 1st, in the Baltic, it quietly dispersed, after accomplishing a journey of over 16,000 in thirty-six days. This is the first storm which has been followed day by day from the Pacific to Europe.

3. "Notes as to the Principle and Working of Jordan's Photographic Sunshine Recorder," by J. B. Jordan and F. Gaster, F.R.Met.Soc. This instrument consists of a cylindrical dark chamber, on the inside of which is placed a prepared slip of photographic paper. The direct ray of sunlight being admitted into this chamber by small apertures in the side, is received on the sensitised paper, and travelling over it by reason of the earth's rotation, leaves a distinct trace of chemical action whenever the light is of sufficient intensity to show a definite shadow on a sundial. The cylinder is mounted on a stand with adjustments for latitude, &c. The record is fixed by simply immersing it in water for a few minutes. As this instrument records the actinic or chemical rays it usually shows more sunshine than is obtained by the ordinary burning sunshine recorder.

GRAFTING OR INARCHING VINES.

IN a recent number of our Journal I read with great interest the remarks on the influence of the stock on the flavour of scion Grapes. I have Madresfield Court worked on Gros Colman, and the fruit from the former has no flavour, being worse than Gros Colman. This is interesting, because if stock is to alter flavour for either worse or better all we have to do is to choose a good stock. I also put Madresfield Court on Gros Colman to test its cracking, the only weakness with me; but this season neither on its own roots nor grafted has it cracked. Gros Colman on Muscat of Alexandria is a decided improvement, with an increase of vigour in growth. I have this summer grafted both Alicante and Gros Maroc on Black Hamburgh, also on Buckland Sweetwater, and I am looking forward with interest to the result in fruiting. Nothing puts new life into old Vines like inarching or grafting. I intend putting Gros Colman on a strong Gros Guillaume.—STEPHEN CASTLE, *West Lynn*.

TUBEROSES.

WERE I asked to name a trio of the most popular white flowering plants in cultivation, I should select the Stephanotis, Gardenia, and Tuberose. At all seasons their sweet-scented and beautiful flowers are highly appreciated and in great demand. The two former, alas! are so much subject to mealy bug and other pests as to make their culture a matter of great difficulty, especially when grown in a mixed collection of plants. Where they can have a house to themselves, and measures applied to keep their enemies from getting a hold, they can be grown to the admiration of everyone who beholds them. The Tuberoses, as far as I know, are free from the many disadvantages which attend the culture of the others; indeed, so easy are they of cultivation, that it is a great pity they are not more generally grown. Many are deterred from growing them by the thought of their requiring a heated house to bring them to perfection, but although a little heat is necessary if they have to be forced into flower for any set time, yet if they are grown and flowered in a cool house they will be much dwarfer in the flower-stem and last longer.

The Tuberose may be started at any time from January till May for those who have not the advantage of a heated structure. About the month of April is the best time to pot the bulbs. I offer the following remarks on their culture, which I have followed myself with a fair degree of success. About the second week of April the bulbs are potted singly into $4\frac{1}{2}$ -inch pots, using a compost of two parts good turfy loam, one part leaf mould, one part peat, a handful or two of bonemeal, a little charcoal, and sand to make the whole porous. They are then stood in a cold frame, and no water is given for a few days, and then only enough to keep them moist, as anything approaching stagnation is sure to end disastrously for the bulbs. They take a good time before showing much signs of vitality, but roots are forming, and therefore the young growths get the benefit over those started (which are generally well advanced before any roots are formed for their support), and although they make slow progress the foliage is of firmer texture. As the season advances plenty of air is given morning and night, shading them from the bright rays of the sun. By the end of June they will be growing freely, when a more abundant supply of water is given, as they soon become dry in these small pots. About the beginning of September they are placed in a cool house, with a temperature ranging from 45° to 50° , where they shortly commence to throw up their flower-stems. When wanted in flower about the middle of September the desired number are placed into a house with a temperature of 60° by day and 58° by night. Those in the cool house come in towards the end of October, and the flower-stems will not average more than 2 feet. Coming in at that dull season they are most acceptable.—WM. MARSHALL, *Ayr*.

BRYN GLAS,

THE seat of T. Cordes, Esq., is pleasantly situated on the right bank of the river Usk, and lies about a mile to the north of the flourishing town of Newport, Monmouthshire. The house, which is a modern erection of two storeys, stands on the ridge of a projecting hill near the summit, which rises to the height of 300 feet above the bed of the river, and commands an extensive panoramic view of great beauty on the east, north, and south sides as far as the eye can reach. The view on the west side is hemmed in by rising ground and large trees. The situation for fine landscape of

hill and dale, of wood and water, is well chosen, and could scarcely be surpassed anywhere in this country. Looking in a northerly direction, the view embraces the lofty Sugar Loaf, and a series of high mountains beyond Abergavenny, while nearer hand glimpses of the dark-brown river in its lower reaches are seen for miles, confined by its deep banks, wending its way along through rich meadows, cornfields, and orchards. Facing the east the ground rises gradually from the left bank of the river for a great distance till the view is closed in by a ridge of high hills running north and south. Turning to the left, you see peeping out from amongst the trees "Old Caerleon on the Usk," where the mythic Arthur held his court. On the south you have an extensive view of the Bristol Channel, with its towns and villages along the Somerset coast, and beyond them the undulating hills away in the distance, while the town of Newport, with its shipping in the docks and river, seems to lie at your feet.

The pleasure grounds, flower garden, and shrubberies surrounding the house contain between nine and ten acres. A great portion of this has been taken in lately, and the whole of it has been renovated and much improved by the skilful management of the present gardener, Mr. Wattie, who has had charge of the place for the last fourteen years. The lawn immediately in front of the house has been carried out level for some distance and terraced. From the terraces the ground suddenly slopes in front towards the river, and in a less degree to the right and left of the ridge, far beyond the enclosed portion.

The grounds at the lower extremity are joined by an old plantation named the "Wilderness," which affords a pleasant shady retreat in hot weather. It is six acres in extent, and contains a great many monster Oaks, Elms, Sweet Chestnuts, and other trees. Beautiful winding walks run all through it, and these are bordered in places with large clumps of the ponticum Rhododendron, which grows luxuriantly in the natural soil here, and flowers freely during the early summer months. The grounds around the house have been laid out with good taste, and much consideration has been given, both to beauty and utility, in planting and in laying off the walks. The principal walks lead from the house to the kitchen garden on the north side, and through the grounds on the south side to the "Wilderness," which is entered at the extreme end. From these, other walks diverging at different points encircle the grounds and lead to places of interest. As I have mentioned, Rhododendrons grow well in the natural soil here, and numbers of large clumps of the best named varieties are planted about the grounds. Each of these is planted wholly of one kind, which has a fine effect, the clump appearing as if it was one large Rhododendron during the time it is in flower. Besides these, there are many beds of evergreen and deciduous flowering shrubs and large shrubberies bordering walks and the outer portions of the grounds. The shrubberies in the outer portion are planted next the lawn with herbaceous and other flowering plants. Standard Rhododendrons, and a choice collection of the best Conifera and other trees and shrubs are planted singly in suitable places on the lawn, giving the whole a rich and furnished appearance. The trees and shrubs grow well, and seem to like the soil and situation of Bryn Glas.

Close to the house, on the lawn below the terrace, is a large geometrical design planted in the carpet style of bedding. Though I was never a great admirer of that formal style (might I say of sculptured vegetation?) I must confess that it looked remarkably well at the time of my visit, and Mr. Wattie informed me it looked bright and cheerful in the month of October, when all the bedding plants were gone.

All the forcing and plant houses are in the kitchen garden, except the conservatory, which is attached to the mansion, and a small house at the north end of the grounds for growing Tea Roses, &c. The conservatory is a large span-roofed structure with an ornamental lantern on top. It is 50 feet long, 30 feet wide, and 26 feet high. The sides are 13 feet high, and the front and ends are of wood and glass, and at the back a wall, which is filled with pockets or crevices for growing plants. Amongst those planted on the walls were some remarkably fine *Seaforthia elegans* and other Palms and Ferns, and Lycopodiums growing luxuriantly up to the top of it. The bed in the centre of the house was filled with large Palms, Tree Ferns, Crotons, &c., amongst which were fine plants of *Dicksonia antarctica*, *Cibotium princeps*, *Areca lutescens*, *Cycas revoluta*, and others. The space round the sides was filled with a miscellaneous collection of stove and greenhouse plants, both flowering and fine-foliaged. The pillars supporting the lantern-roof were covered with plants of *Rhynchospermum jasminoides*, *Plumbago capensis*, *Hoya carnosa*, *Euphorbia jacquiniæflora*, and part of the roof and the wall next the mansion were covered with *Bougainvillea glabra*, *B. speciosa*, *Stephanotis floribunda*, and *Luculia gratissima*, which flower freely and produce a pleasing effect at all times.

The kitchen garden lies on the north side of the house, and in close proximity to it. It is screened from the pleasure grounds by a belt of trees, with a shrubbery and an herbaceous border in front of it. The garden is laid out in quarters, which are divided by gravel walks, and the borders by the side of the walks are planted with pyramidal Apple and Pear trees of the best sorts, which are neatly trained and pruned, and in fine bearing condition. Most of them were yielding good crops when I saw them, the quarters inside were well cropped with excellent vegetables, every thing in the garden looking neat and orderly.

The frame ground adjoins the garden on the west side. It is enclosed by high walls, which completely shut it in and protect it from all quarters. Besides the ordinary cool frames and pits, potting shed, store and seed rooms, and compost heap, it contains several ranges of useful span-roofed houses for growing plants and fruits. The first of these contained a good stock of fruiting Pine plants. The varieties consisted mostly of Queens and Smooth Cayennes. They were clean and healthy, and promised well

to produce good fruits. The next division was filled with Orchids, amongst which were good batches of *Calanthe vestita oculata* and *C. Veitchi*, *Cattleya Mendeli*, *C. Trianae*, and *C. Mossiae*. The end of the house was covered with virgin cork, and Ferns, *Selaginellas*, *Begonia Rex*, and other plants were growing over it. Next to this is the succession Pine pit. Pines are grown on one side of it, and Melons in pots on the other. The next division—an intermediate house—was filled with *Odontoglossums* and several other genera of Orchids, and a few fine plants of *Gleichenias* in good condition. The Cucumber and Melon house adjoins this. It was partly filled with plants consisting of *Dracenas*, *Gardenias*, *Ixoras*, and some Orchids. Close to this is the Strawberry house, a neat lean-to building, both light and airy, with a series of shelves on a stage running close up the glass. Some 400 Strawberry plants are forced here annually, and to judge from the plants I saw in preparation they cannot fail to produce good crops.

The vineries, Peach houses, and the principal plant houses occupy the whole of the south wall in the kitchen garden. The ground has a steep incline to the east, and the houses form, as it were, a series of terraces.

fruit. The berries were free from cracking, and the Vine seemed to do fairly well in company with the Peaches. Passing on, we descend another three steps into the late vinery, which is planted with *Gros Colman*, *Black Hamburgh*, *Muscat of Alexandria*, *West's St. Peter's*, *Lady Downe's Seedling*, and *Mrs. Pince*. The Vines looked strong and healthy, and all the varieties were bearing good crops.

Next is the early vinery. It is planted with *Black Hamburgh*, *Muscat of Alexandria*, *Buckland Sweetwater*, and *Foster's Seedling*. The plant stove—a commodious span-roofed house—is next entered. It contained a good collection of flowering and fine-foliaged plants in vigorous health, amongst which were some fine specimen plants of *Croton Victoria*, 5 feet high and as much through. There were also two large plants of *Eucharis amazonica* fully 6 feet in diameter, which have not been potted for the last seven years, yet they are strong and healthy, and produce enormous quantities of flowers during the year; large plants of *Davallia Mooreana* more than 5 feet through, and many others of smaller growth in a flourishing condition. The back wall was covered with a plant of *Stephanotis* in a free-flowering state. Next to this is the house for growing pot Vines. It was

Fig. 72.—BRYN GLAS.

The first at the top of the range—a span-roofed greenhouse—stands on level ground, and acts as a kind of corridor to all the others, which are on a lower level. Each division is entered by a flight of three steps till the stove is reached at the bottom, which is built on level ground. In passing, I may say that Mr. Wattie is a good plantsman, and Bryn Glas till lately possessed one of the finest collections of specimen stove and greenhouse plants in the country. These, for some reason or other, have been dispersed to make room for smaller plants. The greenhouse was filled with a general collection of plants, amongst which were Tuberous *Begonias*, single and double, *Gloxinias*. Tree Ferns, *Rhododendron Countess of Haddington* and *R. Veitchianum*, two splendid varieties. The plants are about 5 feet high, and from 3 to 4 feet in diameter. Tea Roses and the red and white *Lapagerias* were trained over part of the roof and end of the house, and in a case, in an out-of-the-way corner, a fine plant of *Todea superba*, which I look upon as a most unsatisfactory plant, shunning the light and hiding its beauty under a bushel.

Leaving this we entered the early Peach house, which is a lean-to. It is well furnished with fine trees of *Royal George* and *Early York Peaches*, and *Violette Hâtive Nectarines*, which carry good crops annually. The trees were clean and healthy and full of foliage, though the crop had been gathered some time before. At the lower end of the house a Vine of *Madresfield Court Grape* was finishing off a good crop of highly flavoured

filled with a miscellaneous collection of plants in pots. The back wall was covered with *Maréchal Neil* Roses, which were struck from cuttings in the spring. They were strong vigorous plants with shoots more than 6 feet in length, some of which were flowering.

The Muscat house follows. The Vines were planted this spring. They have made strong short-jointed canes which run right up to the top of the house. The border is made by degrees both inside and out. As the Vines grow and fill it with roots a fresh breadth is added. Next to this is the late Peach house. Mr. Wattie adopts the system of planting early and late varieties in the same house, and by this means he can gather ripe fruit from the month of June till September from it—rather a good idea where glass is limited. The varieties planted here are *Prince of Wales*, a large melting late variety, and a great favourite at Bryn Glas; *Late Admirable*, *Lord Palmerston*, *Hale's Early*, and *Pine Apple Nectarine*. The trees were healthy and clean, and the late varieties were carrying a good crop of excellent fruit. Besides this there is a new Peach case covering 60 feet of wall. It is planted with late varieties, which are making splendid growth, and promise to make fine trees. The trees are young, and to make the most use of the structure possible it was planted with Tomatoes, which have produced as good a crop as is almost possible of large finely finished fruit. The varieties are *Stamfordian*, *Trophy*, and *Perfection*. In conclusion, it is right that I should say the magnificent

grounds of Bryn Glas are, through the kindness of Mr. Cordes, thrown open to the public every Thursday during the summer season.—A. PETTIGREW, Cardiff.

BERBERISES.

As the planting of bushes will now occupy the attention of many, there are some good classes of trees and shrubs which I wish to bring under their notice, and amongst these the Berberises deserve to be introduced. We have a very extensive collection of trees and shrubs here, but I do not think there are any more beautiful when in bloom or fruit than Berberis Darwini. The largest of the bushes of it are 12 feet high, wide in proportion, and in April they become a perfect mass of deep golden blossom. The blooms are very double, and are produced in little racemes. They form fruit freely, and in September the branches which were clothed with their golden hues in spring, are bending under a load of deep purple fruit. This variety is evergreen, and one of the best of all. B. Jamiesoni is another of the evergreen type, and stands next to Darwini in merit. B. dulcis is perhaps the sweetest, and B. ilicifolia is very ornamental in the foliage, being sometimes named the Holly-leaved Berberis. The whole of these flower very freely in spring, and are the best of the evergreen varieties.

Amongst deciduous sorts, B. vulgaris is the common kind often seen in woods, B. elegans and B. purpurea being also notable as other good varieties of this section. The Berberises are noted for their accommodating habit. They will grow in almost any soil or situation, or under the shade of other trees. They are conspicuous in woods, especially in autumn, when they are bearing heavy crops of berries, and they are equally so in pleasure grounds and small gardens. They develop all their characters in a poor soil, but if extra luxuriance is desired it must be produced by planting them in good soil; and although I would never dig deeply, or apply much manure for them alone, I would place some good soil near the roots where the soil is naturally poor. Our best specimens are growing in the ordinary soil of our woods and pleasure grounds, but it is moderately good, and I would advise all who plant in light or stony ground to place extra good soil at the roots of those they wish to become fine specimens. The present is a good time for planting, and if small plants 18 inches or 2 feet high are bought in from a nursery, they will bloom the first season and soon become effective bushes.—L. L. M.

CHRYSANTHEMUM SHOWS.

EAST GRINSTEAD.

THE second annual Show of this Society held at the Public Hall, East Grinstead, last week, was a most unqualified success, being largely attended, greatly admired, and the gathering of Chrysanthemums would have done credit to any town far larger than East Grinstead. The number of entries showed a considerable increase on last year, and it was found necessary to utilise much more space for the arrangement of the exhibits, the stage portion of the hall being this year brought into requisition. The quality of the plants and blooms undoubtedly surpassed previous efforts, the tolerably favourable season being, no doubt, mainly conducive to this result. The weather, however, has not been all that floriculturists could have desired, especially in North Sussex, where, owing to the extreme dryness, quite two months of the year were lost. Great credit, indeed, is due to Mr. Wallis and Mr. Badman of East Grinstead for the exquisite taste they displayed in superintending the grouping of the plants, a work in which they laboured and were highly successful. But the main share of the general work fell to Mr. S. Jenks, the energetic Hon. Secretary, who gave complete satisfaction. The main prizewinners were amongst the gardeners Mr. R. White, The Hermitage; Mr. C. Harris, Hammerwood; Mr. S. Jenks, Brambletye; Mr. T. Glen, Worth Park; and Mr. Down, Ashdown Park; but the first-named far outstripped the rest, he taking double the amount in prizes that fell to the share of anyone else. Mr. Moon and Mr. Dawe were the amateur prizewinners, but there was a vast difference in the quality of their exhibits. Mr. Moon's were excellent and gained several first prizes, but Mr. Dawe's fell so far short of them that the Judges only felt justified in several instances in awarding third prizes. Two groupings, each 60 feet square, were shown, and premier honours in this important class fell to Mr. Jenks, who gained it solely for the very effective manner in which his plants were arranged. Many of Mr. White's flowers were far grander and more striking in effect, but they were hurriedly placed in position and being all towering specimens, while Mr. Jenks' gradually rose from dwarfs to standards, forming a pretty sloping bank, the beauty of the former was lost, and the first prize followed suite. The dwarf-trained Pompons with which Mr. Harris took first prize included some handsome plants, one particularly beautiful being Marguerite De Coi. He very closely pressed Mr. White in his contention for the leading prize for a group of six large distinct flowering varieties, that which particularly recommended his group being a Dr. Macary. As we have remarked, Mr. Moon's flowers were very fine for an amateur, notably a magnificently reared Golden George Glenny, an incurved plant, which figured prominently amongst other exhibits in various parts of the Show. Mr. Jenks, as well as in the large group, contributed some grand plants, particularly noticeable being his six specimen Japanese, which were much admired. But, as far as plants were concerned, Mr. White undoubtedly carried off the palm in several of the classes, far outstripping his competitors. His Japanese specimens were masses of immense bloom, a Madame B. Rendatler forming the most striking, but the greatest beauty certainly lay in the dwarf-trained plants, which formed one of the staple attractions of the Exhibition. The group was composed of Golden George Glenny, Prince of Wales, Mrs. George Rundle, La Nymph, Golden Christine, and Mrs. Sharp, and which was the finest it would be hard to say; all were grand and beautiful and trained in a masterly style. His group of large-flowering plants also won good opinions, a Guernsey Nugget being one of the largest and most perfect specimens among the plants in the Show.

Amongst the cut blooms a similar position to Mr. White's was taken by Mr. Glen, who sent the finest flowers on view, some of which it would be difficult to find anything to surpass. The Japanese specimens were very grand both as regards formation, size, richness, and variety of tints. Mr. Down's contributions, notably the Pompons, were also very good, and so were Mr. White's exhibits in these classes.

There was but very little to choose between the plants for table decorations sent by Mr. White and Mr. Jenks, both showing some very pretty and effective plants. Mr. White of Halsford exhibited some beautiful blooms, and would have been more fortunate but the frost affected his plants a short time since, before which his collection was the envy of the gardeners of the neighbourhood. The fruit was placed in an upstairs room and formed a small but choice display.

SHREWSBURY.—NOVEMBER 12TH AND 13TH.

THE third annual Show of the Shropshire Gardeners' and Amateurs' Rose, Fruit, and Chrysanthemum Society, was held in the Corn Exchange on the above dates, and was very successful, especially so far as cut blooms and fruit were concerned. In the open class for twenty-four Japanese and twenty-four incurved a silver cup value £10 10s. was offered, and brought four competitors with splendid blooms, large and fresh. Mr. West, gardener to E. Wright, Esq. of Halston, was first with forty-eight grand flowers, the best Japanese being Golden Dragon, Criterion, Magnum Bonum, Jeanne Delaux, Henry Jacotot, Fair Maid of Guernsey, Boule d'Or, Dr. Macary, Elaine, Mdle Lacroix, La Nymph; incurved, John Salter, Lord Alcester, Beauty, Empress of India, Lord Wolseley, Emily Dale, Queen of England, Nil Desperandum, Alfred Salter, Isabella Bott, and Princess Teck. Mr. Lambert, gardener to Col. Wingfield Ouslow, was second with blooms very little inferior, his Japanese were grand. Mr. Silver, Chirk Castle, being third. Mr. Haggart, Moor Park, Ludlow, fourth. Twenty-four Japanese, distinct, Mr. West was again first, Mr. Lambert second, and Mr. Haggart third.

For twelve Japanese Mr. West was again to the fore with remarkably fine flowers. Mr. Silver second with blooms very little inferior. Mr. Lambert third. For twelve (any variety) Mrs. Bannerman, Roden Hall, was first; G. J. Fox, Esq., second. The plants were not so fine as usual owing to the dull weather. They were not so much in flower as they should be. Mr. Milner, Sundorne Castle, was a good first with six large-flowering plants; Dr. Burd with four standards, and T. Stayney Eyton, Esq., with three large-flowering varieties. Primulas were very fine, T. S. Eyton, Esq., and the Hon. W. Herbert taking the honours in the order named.

Fruit was a grand show, especially hardy varieties, 570 dishes being staged. For the best collection of Apples and Pears Mr. Milner was a good first with seventy-six dishes. Mr. Lambert second with sixty-six dishes. Lord Hill Trevor third. For three bunches of white Grapes, one variety, Mr. Purser, gardener to J. Watson, Esq., and Col. Wingfield second. Three bunches of black, Col. Wingfield first, Miss Bannerman second. Four bunches, four varieties, J. Watson, Esq., was again to the fore. Mr. Milner second. The amateur classes were well filled, and some fine fruit was shown; G. Burr, Esq., W. W. Humphrey, Esq., Mr. C. H. Matthews, and Dr. Burd being the principal prizetakers.

A fine collection of Apples and Pears, not for competition, were staged by Messrs. F. & A. Dickson & Sons, Chester; and a fine group of Chrysanthemums and Primulas, also a splendid lot of cut blooms were exhibited by Messrs. Jones & Sons, Shrewsbury, not for competition.—H. JONES.

YEovil.—NOVEMBER 17TH.

JUDGING from the excellent start made last year, and taking into consideration the liberality of the prize list, we were fully prepared to see a really good show, and we were not disappointed. In one important respect the Yeovil differs from all other Chrysanthemum shows, as the promoter, Mr. C. Tite, is both Honorary Secretary and principal patron, the support he receives in the shape of subscriptions being almost trivial; or to be plain he is the proprietor, and it is to be hoped he will not be a loser by his public spirit. The gardeners in the district have not yet attempted to compete with trained specimens, and they are wise in this respect, as unless they are done well they present a very poor appearance indeed. Groups occupy a prominent place on the prize list, and of these there were nine creditable lots arranged. The largest, to occupy a space of 10 by 5 feet, were to consist principally of Chrysanthemums, and in this class Mr. T. Hannan, gardener to J. E. Whitby, Esq., Yeovil, was first, his Chrysanthemums being dwarf, fresh, and well flowered; and he also had some well-grown Poinsettias, Eucharises, and other plants. Mr. W. Appleby, gardener to T. W. Dampier-Bide, Esq., Yeovil, was second, his very pretty group including several well-flowered Calanthes, Odontoglossums, and fine-foliaged plants, but his Chrysanthemums were poor; and Mr. W. Pollard, gardener to W. Batten, Esq., Aldon, Yeovil, was a good third. With smaller groups the prizewinners were Mr. G. Gear, gardener to Mrs. Green, Yeovil; Mr. C. Anthony, gardener to T. Moore, Esq.; and Mr. A. Crossman, gardener to J. Brutton, Esq., Yeovil, the two former being considerably ahead of the remaining exhibitors. The silver medal of the National Chrysanthemum Society, offered for six plants of incurved varieties of Chrysanthemums, was won by Mr. W. Pollard, who had fresh freely flowered specimens of Alfred Salter, Mrs. G. Glenny, Mr. Bunn, Prince of Wales, White Queen, and Snowball. Mr. L. Russell, gardener to Major Aldworth, West Coker, was second in this class; and Mr. G. Rendell, gardener to Mrs. Nicholson, third; and with three plants the prizewinners were Messrs. Hannan and G. Gillingham, gardener to R. Phelps, Esq., Yeovil. Mr. L. Russell was the winner of a silver medal N.C.S. for six plants of Japanese varieties; Mr. Pollard being second and Mr. G. Rendell third, all exhibiting creditably. The prizewinners with three Japanese varieties were Messrs. G. Gillingham and T. Hannan.

Cut blooms were largely shown, the competitors including several notable growers. The silver cup, value £5, offered for twelve incurved and twelve Japanese varieties, was won by Messrs. W. & G. Drover, Eareham, Hants; Mr. Willis, gardener to Mrs. Pearce, Southampton, being a remarkably close second, and Mr. H. R. Ward, gardener to the Earl of Radnor, Longford Castle, a good third, and there were five other competitors. Messrs. Drover's incurved varieties were very fresh and of good form, but the Japanese were slightly inferior. They were arranged as follows:—Back

row, incurved—Jeanne d'Arc, Lord Alcester, Snowball, and Golden Empress—Middle row—Beauty, Princess of Teck, Golden Queen of England, and Lord Wolseley. Front row—Robert James, Princess of Wales, Nil Desperandum, and Cherub. The back row of Japanese consisted of Mons. Léo Brunel, Baron de Prailley, Fair Maid of Guernsey, and Triomphe de Rue des Chatelets. Middle row—Roseum Superbum, Meg Merrilees, F. A. Davis, and Madame Lacroix, the front row being Fanny Bouchardet, Fernand Feral, Grandiflorum, and Madame C. Audiguier. Mr. Willis had one very faulty bloom which just spoilt his chance of winning, and as it was he was only two points behind. His best blooms were Miss M. Morgan, Queen of England, Mrs. W. Shipman, Lord Alcester, Cherub, and Lady Hardinge, incurved varieties; and Meg Merrilees, Criterion, F. A. Davis, Japonaise, Boule d'Or, and Baron de Prailley, Japanese varieties. In Mr. Ward's stands were fine blooms of Fair Maid of Guernsey, Baron de Prailley, Boule d'Or, and Comte de Germiny. Messrs. Drover was also first for twelve incurved, Mr. Willis being again second, and Mr. Runnacles, gardener to the Hon. H. Sturt, Sherborne, was a creditable third. With six incurved varieties Mr. Ward was first, Mr. W. Iggulden, gardener to the Earl of Cork, Marston House, Frome, a very close second, and Mr. Guppy third. There were seven good lots of twelve varieties of Japanese sorts shown, Mr. Iggulden taking first prize for well-grown blooms of Grandiflorum, Madame C. Audiguier, Fair Maid of Guernsey, Thunberg, Belle Paule, J. Delaux, Comte de Germiny, Mons. Ardene, Boule d'Or, Meg Merrilees, Peter the Great, and Fanny Bouchardet. Mr. Willis was a good second, and Messrs. W. & G. Drover third. Mr. Ward was first for six Japanese, having fine blooms of Fair Maid of Guernsey, Madame C. Audiguier, Fanny Bouchardet, Comte de Germiny, Grandiflorum, and Ethel. Mr. G. H. Gopp was second, and Mr. R. Guppy third. Mr. Ward was first with twelve reflexed blooms in not less than six varieties, having very good Pink and Golden Christines, Dr. Sharp, Mrs. Forsyth, Gloria Mundi, and King of the Crimson. Messrs. W. & G. Drover were second, and the latter had the best Anemone-flowered varieties, among which were good blooms of Fabias de Maderanaz, Madame Cabrol, Minnie Chate, Empress, Lady Margaret, Fleure de Marie, and Acquisition. With twelve bunches of Pompons Mr. Hannan was easily first, having Marabont, Mdle. Marthe, Florence Nightingale, and Rose Trevenna, in good condition. Mr. J. Rendle was second. A special prize was offered for the best blooms of incurved variety in the Show, and a fine bloom of Golden Queen of England in one of Messrs. Drover's stands was selected, while in a corresponding class for a Japanese Mr. Iggulden won with a perfect bloom of Grandiflorum.

In the classes for table plants, Palms, berried plants, Primulas, Violets, and Mignonette the principal prizewinners were Messrs. W. Appleby, T. Holford, G. Gear, A. Crossman, E. Biggs, gardener to Gen. Henning, Frome Whitfield, Dorchester, W. Pollard, J. Gillingham, and C. Anthony, the exhibits being numerous and good in each case. A considerable number of choice and very useful flowering and fine-foliaged plants were also kindly lent by Mr. B. R. Davis, nurseryman, Yeovil, and also by Mr. Harris of Dorchester; cut Roses being contributed by Mr. Jarman of Chard. Several classes were provided for vases of cut Chrysanthemums, Ferns, and foliage, bouquets of Chrysanthemums and table decorations, vases and baskets filled with autumn leaves and berries, these being open to ladies only. Those who displayed the best taste were Mrs. Biggs, Mrs. Brutton, Miss Curtis, Miss Vining, Miss Mayo, Miss Bond, and Mrs. Hall.

The display of Grapes, Pears, and Apples was highly satisfactory and equalled the cut blooms for attractiveness. There were six lots of Alicante shown; Mr. Iggulden taking the first prize with medium-sized bunches, the berries being large and well finished. Mr. Biggs was second; and Mr. G. R. Daley, gardener to T. Todd-Walton, Esq., Wincanton, third, both having large bunches, but not cleanly shown. In the class for any other black variety Mr. Biggs was easily first with fine bunches of Mrs. Pince; Mr. S. Pullman, gardener to R. B. Sheridan, Esq., Frampton Court, Dorchester, following with good bunches of Lady Downe's, badly rubbed however; and Mr. J. Allister gardener to the Rev. St. John Mildmay, Sparkford, Bath, was third with small bunches of Gros Colman. Mr. Pullman had the best Muscat of Alexandria, Mr. Iggulden being second, and Mr. G. Read third; and in a class for any other white Mr. Iggulden was first with good bunches of Mrs. Pearson, and Mr. G. R. Daley second with Foster's Seedling in good condition; third Mr. F. Case. In a large class for a single dish of Pears Mr. Harris was first with good Marie Louise; second Mr. C. Bowers, who had very fine Pitmaston Duchess; and third Mr. Iggulden with Marie Louise: while the prizes for stewing Pears went to Mr. R. McWilliam, gardener to Sir G. S. Stuckley, Bideford; second Mr. A. Phillpot, and third Mr. Case, all having fine fruit of Uvedale's St. Germain. The best three dishes of dessert Apples, consisting of Blenheim Pippin, Scarlet Nonpareil, and Ribston Pippin, were staged by Mr. C. Anthony; second Mr. Iggulden, third Mr. E. Harris. Mr. J. Mundell, gardener to R. Thornton, Esq., was first for three varieties of culinary Apples; second Mr. J. Bowles, gardener to Major Godden; third Mr. J. Hall, Crocombe, Wells; and fourth Mr. Biggs, all having fine heavy fruit of good sorts. Mr. John Scott, Merriott Nurseries, also contributed a fine collection of Apples not for competition, some of the best of which were Sturmer Pippin, Cox's Orange Pippin, Cornish Gilliflower, Kerry Pippin, Pitmaston Nonpareil, Adam's Pearmain, Mère de Ménage, Hollandbury, Annie Elizabeth, Tom Putt, Golden Noble, Peasgood's Nonesuch, Royal Somerset, New Hawthornden, and Cellini.

CUCKFIELD.—NOVEMBER 18TH AND 19TH.

Last year, the gardeners in the neighbourhood, with the approval of their employers, held a Chrysanthemum show, the proceeds of which were sent to the Gardeners' Royal Benevolent Institution. The result has been that the Chrysanthemum fever has taken root in the district, for as the season drew on it was generally felt that steps should be taken to have another show. It was too late to issue a prize list, so it was decided to hold a show on the same basis as last year—namely, invite all to stage plants, fruits, &c., not for competition. In response to this invitation, seven very creditable groups and about 170 dishes of fruit was staged. The following gardeners staged groups—Messrs. G. Stringer, gardener to R. A. Bevan, Esq., Horsgate; T. Burtenshaw, gardener to W. Payne, Esq., Hatchlands; J. Mitchell, gardener to Mrs. Maberly, Myttings; A. Scott, gardener to M. Turner, Esq., Butler's Green; H. Scott, gardener to T. W. Erle, Esq.,

Mill Hall; J. Lingley, gardener to T. W. Best, Esq., Harvest Hill; and Mr. G. Mitchell, gardener to Miss Richardson, Parkfield. Mr. Stringer and Mr. J. Mitchell also contributed collections of Apples and Pears of very good quality. Fruit was also staged by Mr. J. Harding, gardener to B. B. Hodgson, Esq., Bolney, a very fine lot; Mr. R. Inglis, gardener to T. T. Cunliffe-Lister, Esq., Borde Hill, who showed some good Black Alicante Grapes; R. Hudson, gardener to Major Sergeson, Cuckfield Park; Mr. E. Norris, Broad Street; Mr. H. Jenner, gardener to Miss Ingram, Chownes; C. Tompsett, gardener to Rev. F. G. Mount; Mr. W. Manton, gardener to Mrs. Borrer, Pickwell Lodge, who also showed fifteen dishes of Potatoes; Mr. J. Lingley; Mr. J. Umpleby, gardener to H. Woodcock, Esq., twenty-four dishes Apples and Pears, all from dwarf bush trees, a very good collection; Mr. G. Warren, gardener to Mrs. Hanky, Balcombe Place, also showed twenty-four dishes, an interesting lot. Special prizes were offered by a few of the Committee for a tray of vegetables; Mr. Manton was awarded first, Mr. Stringer second, and Mr. J. Mitchell third. It was evident from the appearance of some of the vegetables in one of the trays that this was not their first appearance on the exhibition table. Vegetables, when staged, should at least show by their freshness that they have come straight from the garden, and it is much to be regretted that anything but fresh samples should be brought forward, if for no other reason than that it prevents insinuations being made for which there may not be the slightest foundation. The Show was fairly well attended, especially in the evenings, and it is to be hoped a small balance may be left for a future event.

BURTON-ON-TRENT.—NOVEMBER 18TH AND 19TH.

THE first Chrysanthemum Exhibition was held in St. Paul's Institute, a building at once handsome, spacious, lofty, and comfortable—comfortable both to plants and visitors, the floor being of wooden blocks placed in echelon, and the room heated by means of hot water. At one end is an orchestra and a beautiful organ, upon which recitals were given each day. The Exhibition florally was a complete success, and would vie in quality of produce with others longer established and of greater renown. The specimen Chrysanthemums—incurved and Japanese—exhibited by Mr. Prince, gardener to the Misses Gretton, Bladon House, Burton, were thoroughly well grown and flowered, and worthy of a place at the best exhibition in the country; these were worthily awarded first prize in each case. The Mayor of Burton (Alderman Lowe) exhibited a very beautiful standard Chrysanthemum (Mrs. Rundle) with a large head of perfect flowers not trained in the stiff manner too frequently seen. The groups of Chrysanthemums arranged for effect down one side of the room were generally of good quality, and presented a huge bank of brightly coloured flowers. The first prize in this class was well won by Mr. Warren, gardener to T. Robinson, Esq.

Cut blooms were well represented and were of good quality, the first prize for twenty-four incurved and twenty-four Japanese being awarded to Mr. J. C. Udale, gardener to H. E. Watson, Esq., Shirecliffe Hall, Sheffield. Mr. Howe of Nottingham was a good second in the class for incurved. The first-prize stand for twenty-four blooms (not less than twelve varieties) incurved, contained fresh, solid, smooth, and symmetrical examples of Alfred Salter, Golden Empress, Jeanne d'Arc, Prince Alfred, Nil Desperandum, Mr. Bunn, Beverley, Beauty, Prince of Wales, Lord Wolseley, Lord Alcester, and Golden Queen of England. The second stand contained very good examples of White Venus, Hero of Stoke Newington, Lord Alcester, Venus, Queen of England, Mrs. Shipman, Isabella Bott, and Lady Slade. In the first Japanese twenty-four (twelve distinct) were capital examples of Elaine, Mdle. Lacroix, Soleil Levant, Thunberg, Roseum superbum, &c. Mr. Wilkes, gardener to G. Meakin, Esq., Stone, was a very good second. Sir Henry Allsopp (gardener, Mr. Barker) sent some magnificent cut flowers not for competition, amongst which the most noteworthy were Prince Alfred, Golden Empress, Queen of England, Empress of India, Jardin des Plantes, Empress Eugénie, and Emily Dale, incurved; and Thunberg, Fair Maid of Guernsey, Japonaise, and Mad. C. Audiguier amongst the Japanese.

Fruit was well shown by Mr. Maynard, gardener to Sir G. Beaumont, Coleorton Hall, and by Mr. Brunt, gardener to the Earl of Carnarvon, Brethby Hall.

Groups of plants arranged for effect, Chrysanthemums excluded.—First Mr. Meakin, second Mr. Brunt, third Mr. Johnson. Mr. W. Fisher, Horn-inglow Cross Nurseries, contributed considerably to the success of the Exhibition by sending a beautiful group of plants not for competition, and consisted principally of a background of Palms, clean and healthy, judiciously intermingled with beautiful Poinsettias, Eucharis, Roman Hyacinths, Azaleas, Chrysanthemums, &c. The same gentleman also exhibited a lovely and exquisitely made cross and wreath, wherein elegance and beauty were combined as they ought to be. Mr. Johnson of the Forge Nurseries also exhibited nice plants not for competition.

Mr. Barratt, the Secretary, deserves all praise for his arrangements, and he has been most ably seconded by Messrs. Rudd, Fisher, Cooper, and Lea.

Messrs. Grant, Draper, Johnson, and Cooper divided honours between them in the cottagers' class.

BRISTOL.—NOVEMBER 18TH AND 19TH.

THIS old-established Society appears to possess greater vitality than ever, and it speaks well for the management that the twenty-second annual Exhibition should be one of, if not the very best held in the Victoria Rooms, Clifton. On the whole the trained specimens were scarcely so good as usual, but there were quite enough to form a long and most effective bank, and the groups of Chrysanthemums and groups of miscellaneous plants completely filled the remaining space round the spacious hall. The best six trained specimens of large-flowering Chrysanthemums were staged by Mr. C. Silcox, gardener to W. Vowles, Esq., Brislington, these consisting of Mrs. G. Rundle, Jardin des Plantes, Alma, Sunset, Guernsey Nugget, and Mrs. Dixon, all fresh and well flowered. Mr. Perry, gardener to H. Cruger Miles, Esq., was a good second, and Mr. J. Lee, gardener to T. M. Miller, Esq., third. Mr. Silcox was also first for three plants, having Mrs. G. Rundle, Mr. Naish, and General Bainbridge in good condition. Messrs. W. Butler, J. Lee, and W. Cooper were the most successful with specimen Pompons, while the prizewinners with Japanese varieties were Messrs. W. Cooper, E. T. Hill, and Miss Charles. The single specimens, as usual, were very fine, and included some of the best pyramidal and globularly trained plants we have seen this season. Messrs. T. M. Miller, E. T. Hill, G. Silcox,

and D. Thatcher were the prizewinners in these classes, and the same exhibitors and Mr. Perry were also successful with small trained and naturally grown conservatory plants. The first prize and silver medal of the National Chrysanthemum Society, offered for the best group of naturally grown Chrysanthemums, was secured by Mr. A. Ambrose, gardener to Kossuth Robinson, Esq.; second, Mr. Salter, gardener to H. Oldland, Esq.; third, Mr. Perry, all having very imposing and well grown groups of plants, though not equal to what are to be seen nearer London.

The collections of miscellaneous plants, arranged on a space 10 feet by 7 feet, are always one of the principal features at the Bristol shows, and this year they were fully up to the mark. Mr. W. Rye, gardener to J. Derham, Esq., Sneyd Park, was awarded the first prize, a somewhat formal but very bright arrangement, including many well-flowered Calanthes and other Orchids, as well as a variety of flowering plants in season. Mr. Perry was a close second; and Mr. E. Miller, gardener to F. Tagart, Esq., a very creditable third. The last-named exhibitor was placed first for six fine-foliaged plants, having immense and very healthy specimens of *Cibotium spectabile*, *Cycas revoluta*, and *Croton undulatum* and other equally well-grown plants. Mr. Rye was a good second, and Mr. A. Hiscock, gardener to A. W. Summers, Esq., third, an extra prize being awarded to the gardener to S. Budgett, Esq. In the corresponding class for four specimens, Mr. Rye was first, J. Lysaght, Esq., second, and Mr. Hiscock third, all having exceptionally well-grown plants. Table plants were shown in great numbers, the majority of them being highly meritorious. Mr. W. Bannister, gardener to H. St. Vincent Ames, Esq., was first, Mr. T. Gibson, second, and Mr. W. Cooper, third. Mr. Bannister was also the winner of first prize for Ferns, Mr. Miller being a good second; and with a new and rare plant Mr. Miller was first, staging a well-bloomed *Cypripedium Spicerianum*, Mr. Rye following with *Croton princeps*. The prizewinners with Poinsettias were Messrs. E. Miller and T. Gibson, who were placed equal first; with *Bouvardias*, Messrs. Rye, W. K. Wait, and E. Miller; with *Primulas*, Messrs. E. T. Hill, Reuben Bow, and A. Ambrose; *Zonal Pelargoniums*, Messrs. C. Tagart, E. T. Hill, and J. Lysaght; and berried plants, Messrs. S. Budgett, T. Gibson, and W. A. Jones, the competition in each case being close and good.

Cut blooms of Chrysanthemums were shown in great numbers than usual, and with a few exceptions the quality was fairly good. Mr. T. Hobbs was first for twenty-four large-flowering varieties, all to be distinct, but as Empress of India and its synonym Mrs. Cunningham were included, many growers were of opinion that the exhibit should have been disqualified. Besides these there were very good blooms of Prince Alfred, Queen of England, Jeanne d'Arc, Princess Imperial, Prince of Wales, White Venus, Princess of Wales, Lady Hardinge, Golden Beverley, and Barbara. Mr. Ward, gardener to the Earl of Radnor, was a creditable second, and Messrs. W. and G. Drover third. With twelve varieties of incurved sorts, Mr. E. S. Cole, gardener to W. Pethick, Esq., was a good first, Mr. J. Waite second, and Mr. W. M. Baker third; and in the class for six varieties Mr. W. Iggulden was first and Mr. E. S. Cole second. Messrs. Drover had the best Anemone-flowered varieties, Mr. E. S. Cole being second. There were two classes provided for Japanese varieties, and these attracted the greatest number of entries. For twelve distinct varieties Mr. W. Iggulden was first, having fine blooms of *Grandiflorum*, *Madame C. Audiguier*, *Mons. Ardene*, *Boule d'Or*, *Belle Paule*, *Meg Merrilees*, *Thunberg*, *Comte de Germiny*, *Fanny Bouchardet*, and *Fair Maid of Guernsey*. Mr. E. S. Cole was a good second, and was also deservedly first for twelve blooms in not less than six varieties, Mr. Iggulden being a close second, and there were several others only slightly inferior. Bouquets, wreaths, vases, and baskets of both choice flowers and autumn leaves and berries were all shown in great numbers, the exhibitors in most cases displaying most commendable taste. The principal prizewinners were Messrs. M. Hoskings, E. S. Cole, E. T. Hill, Miss Wetherhed, Mr. C. Winstone, Mr. J. Rogers, Mr. H. Mardon, Miss Dobson, and Mr. G. Garraway.

Fruit was largely shown, and included Grapes, Pine Apples, Melons, Pears, Apples, and Medlars. There were eight classes provided for Grapes alone, and in nearly every case the competition was very keen. Mr. Nash, gardener to the Duke of Beaufort, was well to the front, being first for Alicante, Gros Colman, and any other black variety, his exhibits in each case being of the highest order; and the same may be said of the Muscat of Alexandria staged by Mr. Ellicott, gardener to H. W. Tugwell, Esq., and Mr. F. Nicoll, gardener to Mrs. Miller. Mr. Ellicott was also first for Black Hamburgh, and Mr. Bannister second, while the best Lady Downe's were staged by Mr. C. D. Cave, the second prize going to Mr. V. Down. Mr. W. Taylor, gardener to J. Chaffin, Esq., was also successful in the classes for Alicante, Gros Colman, and any black variety not of Muscat flavour, his exhibits being most remarkable for good finish. In the last named class Mr. Nicoll was a good first with Mrs. Pince, well finished, and in a corresponding class for white varieties Mr. Rye was first with excellent Buckland Sweetwater, Mr. Iggulden following with good examples of Mrs. Pearson. A special prize was offered for the two heaviest bunches of Grapes in the Show, and this was won by Mr. Down, who had immense clusters of Gros Colman, each weighing about 8 lbs., but they were badly coloured. There were six competitors with a collection of six dishes of fruit, Pine Apples excluded, Mr. Nash being placed first with capital samples, very similar to the collection he had at Bath, and Mr. T. Every was a good second, Mr. W. Bannister third, and an extra prize was given to Mr. Nicoll; the Black and Muscat Grapes being very good in each instance. In a large class of six varieties of Pears Mr. W. Bannister was first, and Mr. Rye second, and with four dishes these positions were reversed, the fruit, principally grown on bush-shaped trees, being very fine in each case. Mr. Bannister had also the best single dish of Pears, Marie Louise very fine, and the best six dishes of Apples. Other successful exhibitors of Apples in the various classes provided being Messrs. J. H. Virgo, E. Hall, E. T. Hill, E. Sweeting, W. M. Baker, and G. Garraway.

The array of vegetables (for which one class only was provided, in the form of a collection of ten distinct varieties) was remarkably good, excelling anything of the kind hitherto seen at Bristol. Mr. E. T. Hill was first, Mr. T. Every second, Mr. W. Bannister and Mr. W. M. Baker equal thirds, and an extra was given to Mr. W. P. Emerton. These were several non-competitive exhibits, the most noteworthy being a grand lot of Chrysanthemum blooms staged by Garaway & Co., Durdham Down Nurseries,

Clifton, and which comprised many new and all the best older varieties. Mr. J. Austin, Witley Court, had several very fine fruits of Smooth Cayenne Pine Apples, which attracted much attention. The Show was fairly well attended, and the arrangements were perfect.

LEWISHAM.—NOVEMBER 18TH.

A VERY successful inaugural Exhibition of Chrysanthemums was held in connection with the recently formed Lewisham and District Floral Society in a hall in a central position of Lewisham, on Wednesday last, November 18th. The Society was only formed a few days before the Show, but so energetic were the efforts of the Committee (who are enthusiastic amateurs and City gentlemen) that, although no prizes were offered this year, plenty of friends were found willing to contribute stands of cut blooms and groups of plants, and thus render it an attractive and successful Show. Messrs. J. Laing & Co. of Forest Hill contributed a very fine group of Chrysanthemums, and Messrs. Jones, Jupp, Needs, Stone, Berry, Forrester, Harry, and Drake stands of cut blooms. The last-named gentlemen are amateurs, and their exhibits did them great credit. The public evidently appreciated the efforts of the Committee, for the place was thronged with visitors. With the name of the author of "The Chrysanthemum, its History and Culture" as one of its Vice-Presidents, and Mr. Drake as the able Secretary, this Society will, we hope, prove equally if not more successful another year.

BIRMINGHAM.—NOVEMBER 18TH AND 19TH.

ONLY a very few years ago this Society was, in the estimation of many persons interested in it, in a moribund state, whereas it is now in a strong and flourishing condition. A spirited yet prudent policy has resulted in larger and better shows, greater public patronage, and more satisfactory finances, the last statement published showing a substantial balance, including the reserve fund of upwards of £150. The autumn shows in the Midland metropolis have long been famed for splendid specimen Chrysanthemum plants and Primulas, but superior cut blooms of Chrysanthemums were not encouraged nor produced. Fine specimen plants are still grown in the district, and nowhere else can anything approaching such a display of Primulas be seen, while now, in addition, the exhibition of cut blooms of Chrysanthemums is one of the greatest of the year.

The Show under notice was held in the fine Town Hall, which was crowded with exhibits and visitors to such an extent as to render more space desirable. As in the case of most, if not all, other shows this year, dwarf-trained Chrysanthemums were neither so numerous nor on the whole so good as have been seen on previous occasions, but groups of untrained plants were added, and these, with beautiful nurserymen's collections, occupied the space effectively. By far the finest dwarf-trained plants were the nine to which £5 was awarded—grown and exhibited by Mr. W. H. Dyer, gardener to Mrs. Marigold, Edghaston, a well-known and highly successful exhibitor. He was in the first position for six plants, and also for a single specimen. Mr. Martineau, Birmingham, was notably successful in the plant classes, being adjudged first prizes for three large-flowering Chrysanthemums, six Pompons, one Pompon, and one Japanese. The Society offered a special prize of £4 for a bank of natural-grown Chrysanthemums, which was won by Mr. Pattison with a very creditable arrangement, two other collections being staged. In the class for nine stove and greenhouse plants the chief prize was won by Mr. F. A. Walton, while that for six plants went to Mr. Dyer, both exhibiting well.

CUT BLOOMS.—Though there was an extensive display of these there were no stands of a substantial character. The prolonged term of cold weather appears to have retarded the development of the flowers, and numbers of them had not arrived at their best condition, therefore freshness rather than weight was the characteristic of this department; also the chief prize of £10 failed to elicit a response from Liverpool and other distant Chrysanthemum-growing districts. This was all the better for the "local men," and credit is due to them for contributing to the success of the Show, indeed, for making it so superior to the exhibitions of half a dozen years ago. It is gratifying to observe this marked improvement which is the main and ultimate object of promoters of shows. As to attracting distant competitors, or rather the best examples of culture obtainable, that is obviously desirable, but it will be more difficult to secure these in the future by offering, say, a £10 prize for forty-eight distinct varieties. There are several prizes of that nature now-a-days, and exhibitors can "take their choice," and it seems they choose to compete for that sum where it is offered for a less number of sorts. This is perhaps not much to be wondered at, and framers of schedules will act accordingly either in increasing the amounts offered or restricting the number of varieties. At Birmingham the prizes for forty-eight blooms distinct, twenty-four incurved and twenty-four Japanese, fell to Mr. P. Southby, who staged fresh medium-sized examples of the popular exhibition varieties. In the class for twenty-four blooms, twelve Japanese and twelve incurved, there was good competition, the premier award being granted to Mr. G. A. Everett for excellent stands. Mr. H. Lovatt was the chief prizewinner in the class for eighteen incurved blooms with fresh and good examples, most of the others being undeveloped. Mr. Southby was placed first for twelve blooms of Japanese with the best stand in the Show, the blooms being large, fresh, and richly coloured; also for twelve Anemones, the flowers being of average merit. Prizes were offered for blooms grown within three miles and twelve miles respectively from Stephenson Place, and several stands of great merit were placed in competition. Mr. Madeley was the successful exhibitor of twelve blooms within the three-mile radius, and Mr. G. Everett secured the chief prizes for twenty-four and six blooms in the twelve-mile radius. The competition in these classes was very creditable indeed, every stand being worthy of its position in the hall.

PRIMULAS.—There was a magnificent display of these, about 300 plants being placed in competition, and it may be safely said that many of the third-prize collections would have been placed first at the majority of shows in the kingdom. In the open classes all the leading prizes were taken by Messrs. H. Pope & Sons with grandly grown plants, remarkable alike for vigour of foliage and size and freshness of flowers. In the district classes Mr. T. Martineau won the chief prize for twelve plants, Mr. Matthews for six plants, and for three Mr. J. Taunton was the most successful competitor. The plants are generally grown in 6-inch and 7-inch pots, the foliage having a spread of from 18 inches to 2 feet, pyramidal masses of flowers rising in

some instances 18 inches high. The display so far as we are aware has never been equalled at any previous exhibition, and all the exhibitors are to be commended for growing these plants so well.

The first prizes for Epiphyllums, twelve Cyclamens, and Zonal Pelargoniums went to Mr. Cooper, gardener to the Right Hon. Joseph Chamberlain, Mr. A. Clifford being first for six Cyclamens. Mignonette was admirably staged by Mr. T. Martineau, who was worthily adjudged the first prize, Mr. Dyer having a similar award for well-grown Poinsettias. Mr. Cooper arranged a very attractive bank of Orchids, composed of fresh well-flowered plants of *Oncidium verrucosum*, *O. pulverulentum*, *O. Forbesi*, *Cattleya Dowiana*, *C. exoniensis*, *C. Skinneri*, *Odontoglossum biconense*, *O. Alexandræ*, *O. grande*; *Lælia elegans*, very fine; *L. Dayana*, *L. autumnalis*, *Cypripedium Spicerianum*, *C. Sedeni*, *Cymbidiums*, *Calanthes*, *Masdevallia tovarensis*, and *Monoepidium vulcanicum*. These, with a number of excellent bouquets, produced a beautiful effect at one end of the hall.

FRUIT.—There was not a very large display of fruit, but the quality was quite first-rate, especially of Grapes, which were wonderfully well finished. The best three bunches of black Grapes were exhibited by Rev. B. W. Stanners; Muscats, Mr. J. Corbett; other white Grapes, Mr. G. A. Everett. In the single bunch class Mr. Corbett was first with black, and Mr. Stanners with white Grapes. Messrs. Corbett and Higgins took the chief prizes for Apples and Pears, staging excellent dishes.

Various miscellaneous contributions of plants, flowers, and fruit contributed powerfully to the general effect of the Exhibition. Mr. Hans Niemand had a charmingly arranged assortment of choice plants and a meritorious group of Cyclamens; Messrs. Thompson & Co. having a correspondingly good arrangement. At the opposite end of the hall a similar extent of space was effectively furnished by Messrs. Vertegans and Pope & Son; the latter also exhibited a seedling Fern, which was certificated. It is evidently a variety of the elegant *Gymnogramma schizophylla*, of strong growth, and with more widely divided pinnae than the type. We understand the stock was secured by Mr. B. S. Williams of Holloway. It will make a most graceful basket Fern, and probably a fine pot plant for decorative and exhibiting purposes. Messrs. Perkins, Coventry, contributed beautiful floral crosses and wreaths, also a box of extremely fresh cut Roses; Messrs. Richard Smith & Co., a collection of small Japanese Conifers in pots, perfect for window-sill decoration, and an excellent collection of Apples; the Rev. J. A. Williams, Aldermaston, also staged about fifty excellent dishes of Apples, and Messrs. Cannell & Sons, Swanley, splendid stands of Chrysanthemums and Pelargoniums, the rich Chrysanthemum *Cullingfordi* being certificated. The merits of all the exhibits referred to were formally recognised by the Judges.

Owing to the density of the crowd it was impossible to do more than obtain the names of the leading prizetakers in the classes noted, and the great attendance of visitors must have been highly encouraging to all who have laboured so assiduously in making the Show what it was—a great success.

TAUNTON.—NOVEMBER 19TH.

THIS thriving young Society held its third annual Exhibition in the Castle Hall, and is to be congratulated upon the successful results attending the efforts of Mr. R. H. Poynter, and the active Committee of practical gardeners. The early frosts appeared to have worked much mischief in this district, especially among the specimen trained plants, while the cut blooms were much later than they are in presumably less favoured localities, and this, as it happened, gave the local growers a decided advantage in point of freshness over those who came from a distance. Specimen plants were not largely shown, the principal exhibitor of these in the open classes being Mr. H. Godding, who had several prizes for incurved and Japanese varieties. The four best bloomed specimens in the Show were exhibited by Mr. J. Parrish, gardener to Mrs. Eden, the sorts being Fair Maid of Guernsey, Madame Bertie Rendatler, Bouquet Fait, and Peter the Great; and Mr. W. Thomas, gardener to W. Marshall, Esq., also exhibited successfully in this class. Mr. Thomas was also first for a single specimen, staging a well-flowered Peter the Great. Mr. W. Cavill, gardener to H. F. Manley, Esq., and Mr. C. Lucas, gardener to John Marshall, Esq., exhibited well and successfully in several classes for Chrysanthemum plants. Mr. T. Wilkins was first for six untrained plants, Mr. G. Henley, gardener to F. Woodland, Esq., taking second prize, both having freely flowered healthy plants. Mr. Wilkins was also first for a group of Chrysanthemums, and Mr. W. J. Turk was a good second, the exhibits in each case being very praiseworthy.

Classes were provided for groups of mixed plants, and for a group from which Chrysanthemums were excluded. The first prize for the former, a silver cup value £5 5s., was won by Mr. C. Lucas, who had a very bright and pleasing group, which comprised a very strong plant of *Anthurium Andreanum*, *Pancratium speciosum* with ten strong flower-stems, a good plant of *Cypripedium insigne punctatum violaceum*, *Calanthes*, *Crotons*, *Dracænas*, Ferns, Chrysanthemums, and a variety of other plants. Mr. Thomas took second prize for a very excellent lot of plants; Mr. H. Godding was a good third, and Mr. R. H. Poynter was highly commended for a neat lot of plants. Mr. Thomas arranged the best group from which Chrysanthemums were excluded, and his most noteworthy plants were a good specimen of *Croton Johannis* and *Anthurium Andreanum*. Mr. T. Essex, gardener to S. Reynolds, Esq., took the second prize for a lot of healthy plants, but which presented a somewhat dull appearance. The best six Ferns were shown by Mr. Henley, and Mr. W. B. Hellard was a good second, and for the same number in small pots Messrs. Parrish and Mr. Henley were successful. Primulas were shown in great numbers, and the majority of them were good indeed, several strong well-flowered plants of Carter's Holborn Blue being included. Mr. C. Cooper, gardener to C. L. Collard, Esq., was first, Mr. W. Cavill, second, and Mr. J. Wakefield third; and with doubles Messrs. J. Wakefield was first, and Mr. Lucas second. The Cyclamens were remarkably good, notably the first and second prize lots staged respectively by Messrs. Lucas and J. Parrish. The prizewinners for table plants were Messrs. W. J. Crossman, gardener to H. A. Bosanquet, Esq., B. T. James, gardener to Sir W. Lethbridge, and Mr. Hellard, who each had several good plants. The classes for cut blooms, both open and confined to the locality, were well filled, the Judges necessarily bestowing much time in making the awards. The premier prize, that for thirty-six blooms, half to be incurved and the remainder Japanese, was won by Mr. C. Cooper; Mr. Wills, gardener to

Mrs. Pearce, Southampton, taking the second, and Messrs. W. & J. Drover were highly commended. The former's exhibit included fine fresh blooms of Lord Wolseley, Lord Alcester, Golden Queen of England, Mr. Howe, Jardin des Plantes, Lady Hardinge, Hero of Stoke Newington, Empress Eugénie, Princess of Teck, and Mrs. W. Shipman, while some of the best among a generally excellent lot of Japanese sorts were Japonaise, M. Ardenne, Comtesse Beauregarde, M. Astorg, J. Delaux, M. Delaux, Fanny Bouchardat, and Madame C. Audiguier. Mr. Wills had much the best incurved sorts, but was weak with the Japanese. With twelve incurved and twelve Japanese Messrs. W. & J. Drover and Mr. Wills were placed equal first, the third prize going to Mr. C. Lucas. Some of the best represented incurved sorts were Princess of Teck, Golden Queen of England, Cherub, Barbara, Lord Alcester, Baron Beust, Pink Venus, Hero of Stoke Newington, and Japanese Baron de Prailley, Boule d'Or, Criterion, Golden Dragon, Meg Merrilees, Fanny Bouchardat, Triomphe de Rue des Chalets, and Fair Maid of Guernsey. Mr. C. Lucas had the best twelve incurved sorts, Messrs. Drover being a good second, and Mr. Wills was easily first for reflexed varieties. Mr. C. Cooper repeated his former success with twelve Japanese varieties, his capital lot including fine blooms of Comtesse Beauregarde, J. Delaux, M. Ardenne, Meg Merrilees, and Golden Dragon. Mr. Thomas was a good second, and Mr. Parrish third. In the other classes for cut blooms Messrs. Cooper, Lucas, Thomas, and Parrish were the principal prizewinners.

Grapes were not largely shown, and of these Mr. T. W. Samson, gardener to the Rev. A. Elton, and Mr. T. B. Hellard were the principal exhibitors; and in the various classes for Apples and Pears the most successful were Mr. A. Tucker, gardener to Captain Winter, Mr. G. Henley, the Rev. J. P. Hewitt, the Rev. E. Woodhouse, Mr. Samson, Mrs. V. S. Reynolds, Mr. Lucas, and others whose names we were unable to procure. Mr. Nicholas, gardener to the Earl Fortescue, Castle Hill, Devon, exhibited a very fine Smooth Cayenne Pine Apple, not for competition, and there were several other interesting non-competitive exhibits.

NEWPORT, MONMOUTHSHIRE.

THE Newport and County Horticultural Society held their second Chrysanthemum Show in the Albert Hall, Newport, on the 19th inst. Last year the Society lost money by the Chrysanthemum Show, but the balance was on the right side at the summer show in July; and encouraged by this the energetic Hon. Secretaries, supported by some enthusiastic members of the Committee, decided to try another Chrysanthemum Show, and if the financial department was as great a success as the horticultural department those who take such a laudable interest in the affair will have good reason to be satisfied with the result. The Show was the finest in the principality or near its borders. Creditable as the first Show held in November, 1884, undoubtedly was, the one just held was of much greater excellence. Indeed, the Newport Show will very soon take its place and be regarded as one of the notable Shows in the kingdom, and the exhibits now sent from Liverpool, Bristol, Bath, and other distant parts indicate the confidence cultivators place in the management of the Exhibition.

The Right Hon. Lord Tredegar gave the first prize in Class 1, which was for six large-flowering plants, and this was won by Mr. George Fothergill with specimens not quite so large as some shown in the same class, but the blooms were extra large and very fresh. Mr. H. J. Davis was second, four of his specimens being very good, but two poorly trained ones were against the success of the group. Mrs. Cartwright, Springfield, was a close third, and some good plants remained unnoticed, although the specimens forming the half-dozen are not uniformly fine. In the class for four Japanese varieties Mr. Fothergill was first with handsome fresh specimens of Mons. C. Huber, Hiver Fleuri, Margot, and Peter the Great. The second award fell to Mr. C. T. Wallis, and the third to Mrs. Cartwright. A very good class throughout. Standard plants were numerous and good: Mr. H. J. Davis being first with four plants rather closely tied in, but profusely flowered. Second Mr. E. J. Grice with plants finely bloomed but deficient in foliage. Third Mrs. Cartwright, with small heads but good flowers. Pompon varieties were not quite so numerous, but some of the plants were excellent. Mr. H. J. Davis and Mrs. Cartwright divided the prizes. The class for four plants, large-flowering, distinct, brought out some fine specimens, and it was here that the largest flowers on any of the plants was to be seen. Mr. G. Fothergill being first with Mrs. Forsyth, Julia Lagravère, Jardin des Plantes, and Plancherone. Mr. H. J. Davis was second. In single specimen plants Mr. H. J. Davis was first with a plant of Mrs. G. Rundle, 5 feet through, finely bloomed. Second Mr. Fothergill with Empress of India, magnificent blooms. Third Mr. E. J. Grice, with King of the Crimson, poor.

Cut blooms were the great feature of the Show; they were magnificent. For the best twelve blooms, large-flowering, Japanese excluded, Mr. H. J. Davis was well to the fore with a grand stand of the following:—W. H. Morgan, Beverley, Prince Alfred, Mrs. G. Rundle, Bronze Jardin des Plantes, Emily Dale, Mr. Howe, Lord Wolseley, Golden Empress of India, Mrs. J. Crossfield, Hercules, and Miss Wetherell. No attempt had been made to dress these, being shown quite naturally, and they won well. Mr. Thomas Hobbs, Bristol, was a good second, but blooms smaller as a rule. In the class for twelve Japanese blooms Mr. E. S. Cole, Bristol, was a grand first with large blooms in fine condition of Album Plenum, Madame C. Andiguier, Grandiflorum, Margaret Marrouch, Sarnia, Meg Merrilees, Baron de Prailley, Fanny Bouchardat, Peter the Great, Fair Maid of Guernsey, Thunberg, and Comte de Germigny. Mr. John Atkins, Liverpool, was second, and many of his fine blooms equalled those in the first stand; but one or two of them had suffered in transit. In the class for six blooms those two exhibitors again occupied their previous positions, Mr. Cole having a very effective six. The second blooms were also good, but not so distinct as the first. Many fine lots in both of these classes were obliged to remain without a special mark of merit, which they certainly deserved.

Prizes were offered for a collection of stove plants, and many competed. They were arranged along the centre of the spacious Hall, and the Chrysanthemums formed a beautiful boundary to them. Mr. E. J. Grice succeeded in carrying off his own prize, and Mr. T. Watson was a close second. Mr. Whitehouse's collection contained a finely grown and beautifully bloomed plant of *Eucharis amazonica*. Poinsettias were very bright from Mr. Watson. Primulas poor. In coming further down the list we find the

honours of the amateurs' section very creditably upheld by Mr. J. Pickford, whose good plants and perseverance in exhibiting may both be taken as excellent examples by his neighbours. Fruit was not very plentiful, only one collection being staged by Mr. Watson. Grapes were fairly good from Mr. T. Colborne, Sir H. M. Jackson, and Mr. Fothergill. Apples and Pears were uncommonly fine from Mr. G. J. Jones, Mr. E. J. Grice, Mr. T. Colborne, and Sir H. M. Jackson.

Vegetables were numerous and excellent. In the main collection Mr. C. T. Wallis and Mr. D. Whitehouse were successful with fine clean samples. Mr. Octavius Morgan, Newport, exhibited a most interesting collection of cut Chrysanthemums, good blooms beautifully embellished with their foliage.

HULL.—NOVEMBER 19TH AND 20TH.

WHEN it is considered that the Hull Chrysanthemum Society has only been established about fourteen months and has held two Shows, the first being attended by about 4000 persons, and resulting in a balance on the credit side of the ledger of nearly £80, and that the second Show just held included some of the best competition of the year, and the leading class the finest we have seen at any show in any year, the success achieved must be regarded as phenomenal. It must be understood our remarks as to the quality of the Show are confined to the open cut bloom classes. Many excellent blooms were staged throughout, but the stands were not sufficiently numerous to occupy the great length of tahling in the enormous space under the roof of the Artillery Barracks, and the plants in an adjoining annex were relatively inferior. These constituted the weak points of the Show, but the groups of plants arranged for effect were very imposing. As to what may be termed the decorative section of the Show—dessert table competition, bouquets, floral ornaments, &c., we can only say it was so attractive that the room was so densely packed with visitors that we were positively "crowded out." The opening ceremony by the ex-Mayor and his attendants indicated the great public interest that manifested in the event, and with a continuance of public support, with such a practical and energetic Chairman as Mr. Bohn, such indefatigable Secretaries as Messrs. Jameson and Hawksworth, and the first-rate Committee, the Society cannot fail to occupy a very high position in the Chrysanthemum world.

CUT BLOOMS.—For these a challenge vase and a challenge cup were provided, the vase in the open class, the cup in a class for amateurs; and the money prizes in the former were of such value as to enable even the third prizewinner to defray all his travelling expenses, and the fourth to have little to lose. The conditions were also such that enables a majority of skilful growers to arrange superior stands.

The Hull challenge vase, value 15 guineas, is offered by the Chairman of the Society, George Bohn, Esq., a splendid contribution, the money prize being £10 in addition. The vase has to be won twice consecutively, or three times altogether, to be finally claimed by the owner of the winning flowers, the money prizes going to his gardener who grows them. This equitable arrangement is the same as in the great cup class at Kingston-on-Thames. But in the Surrey contest forty-eight distinct varieties have to be staged, whereas at Hull thirty-six varieties suffice in the class of forty-eight blooms—namely twenty-four incurred in not less than eighteen varieties, and the same as regards Japanese. The advantage of this is, that no exhibitor can stage forty-eight varieties so fine as he can that number of blooms in thirty-six varieties, because he is enabled to duplicate twelve of his best if he wishes, and, consequently, exclude an equal number of inferior flowers. There are growers too, able to stage thirty-six varieties creditably who could not make up presentable stands in forty-eight varieties. The strength of a chain is only equal to the weakest link, and the weakness in stands of twenty-four varieties of Chrysanthemums is always found in the last half-dozen blooms; the less the number of varieties, therefore, in a class the stronger the stands must be. This is why the great class at Hull was so weighty. There were five competitors—Mr. Lindsay, gardener to Sir T. Edwardes Moss, Bart., Otterspool, Liverpool (first); Mr. W. Mease, gardener to C. W. Neumann, Esq., Wyncote, Liverpool (second); Mr. Green, gardener to J. Woolwright, Esq., Mossley Hill, Liverpool (third); Mr. J. B. Morton, Mowden Bridge, Darlington (fourth); and Mr. Mitchell, gardener to W. J. Warren, Esq., (misprinted "Waver," in the Lincoln report last week) Bracebridge, Lincoln. The vase thus remains at Otterspool till next November, when Mr. Lindsay will, all being well, no doubt strive for it again, and a few others will strive to prevent him. There is the chance of his flowers not being quite so good next year as this, the chance of those of Messrs. Mease or Green being a little better, and so the scale may be turned, and there is also another chance—of someone else defeating the trio. Mr. Lindsay has come to the front at a bound, and won magnificently, that term applying to the blooms and not to the distance between him and Mr. Mease, who also staged magnificent flowers, but some of the incurred evidently required another week for their full development, or, in a word, Mr. Lindsay's were "in" to the day, and Mr. Mease's were not. That appears to about represent the difference between their incurred, the Japanese being very nearly as close as they could be, the Otterspool blooms only leading by two points out of a possible 144.

Mr. Lindsay's winning stands were furnished as follows, reading each row from left to right—Incurred: back row—Queen of England, Lord Alcester, Empress of India, Alfred Salter, Golden Empress, Empress of India, Golden Empress, Queen of England; second row—Jeanne d'Arc, John Salter, Mr. Bunn, Emily Dale, Bronze Jardin des Plantes, Prince Alfred, Jeanne d'Arc, John Salter; front row—Refulgence, Mrs. Heale, Sir Stafford Carey, White Beverley, Princess Beatrice, White Globe, Lord Wolsley, and Mr. Bunn. Japanese—Madame C. Audiguer, Fair Maid of Guernsey, Criterion, Mons. Tarin, Boule d'Or, Madame C. Audiguer, Fair Maid of Guernsey, Japonaise; second row—Comte de Germiny, John Laing, Boule d'Or, Margaret Marrouch, Elaine, Criterion, R. Ballantine, Peter the Great; front row—Mlle. Lacroix, Thunberg, La Nympe, Soliel Levant, F. A. Davis (J. Delaux), Thunberg, Mons. Desbrieux, and Sarnia. The incurred blooms were generally very large, also firm and symmetrical, and though a few were defective in some point or other the twenty-four secured 115 points of merit out of a possible 144, or an average of 4½ points to each bloom, and this good average was a little more than maintained throughout the Japanese stand. As above intimated, Mr. Mease ran his rival very closely indeed with these, his blooms of Belle Paule, Criterion, Boule d'Or

and Meg Merrilees, being grand examples of high culture, while his incurred blooms of the Queen type, also Jeanne d'Arc, were of similar large dimensions and good quality. Mr. Green's stand contained many handsome flowers, including the premier incurred bloom in the Show—a fresh and beautiful example of Empress of India. We have certainly never seen a collection equal to this placed third at an exhibition before, and such flowers would have been easily first at some other shows where liberal prizes were offered. Mr. Morton also exhibited very well indeed, but both he and Mr. Mitchell were overweighted, and the Lincoln blooms had, moreover, lost their freshness.

The first three exhibitors named held the same relative positions in the next class of twenty-four blooms, twelve incurred and the same number of Japanese in not less than nine varieties of each, the first prize being £5. The stands were extremely fine throughout, and the competition close. In Mr. Mease's the premier Japanese bloom of the Show was found, a beautiful example of Belle Paule being selected in preference to a bloom of the same variety in his forty-eight, because of its smoother and broader florets, though the other was a little deeper in colour. There was no alteration in the winners in the excellent class of twelve blooms of Japanese. In the class for twelve incurred blooms, distinct, there was great competition, the prizes falling to Mr. Mease, Mr. Green, and Mr. Usher, gardener to C. H. Johnson, Esq., Thorgumbald Hall. Three very even and good stands of large Anemone-flowered varieties were exhibited by Mr. Morton, Mr. Bulmer, gardener to D. Wilson, Esq., and Mr. Mitchell, who were awarded the prizes in the order named, there being little to choose between the merits of the collections. Very rich stands of reflexed varieties were staged—twelve blooms in not less than six varieties, Mr. Morton securing the foremost place with two flowers each of Cullingfordi, King of the Crimsons and Chevalier Damage, and one each of Mrs. Forsyth, Sir E. Landseer, and Jewess. Mr. Bugg, Lincoln, and Mr. Usher followed closely in the same class. Mr. Mease staged the best six blooms of any variety—wonderfully well-coloured examples of Bouquet Fait, Mr. Mitchell following with Elaine. The competition in the above classes was open to all.

Four classes were provided for exhibitors in Lincolnshire residing within twenty miles of Hull or anywhere within the East Riding of Yorkshire. In the first of these, for twenty-four blooms, half incurred and half Japanese, in not less than six varieties of each, the first prize, given by Mr. E. P. Dixon, was well won by F. W. Jameson, Esq., with extremely fresh incurred examples, but not quite developed, and good Japanese, Mr. Bulmer being second with rather small but neat, solid flowers, and Mr. Leadbetter, gardener to Arthur Wilson, Esq., Tranby Croft, third with much larger but loose blooms. E. Harland, Esq., Cottingham, secured the first position in the class for twelve incurred blooms, very closely followed by C. H. Johnson and F. W. Jameson, Esq. In the corresponding Japanese class Mr. Bulmer, Mr. F. W. Jameson, and Mr. Brownsho, Beverley, were the prizetakers; and in the mixed class Mr. J. Tall, Cottingham, Mr. Bulmer, and Mr. J. W. Jameson, the former staging among others one of the finest Elaines of the year.

Several prizes were offered for amateurs, or persons who do not employ a gardener, but we can only note that the first prize in the two classes for twelve incurred and twelve Japanese blooms was won by E. Goddard, Esq., with highly creditable examples, and the more so since the owner had only fifteen incurred blooms altogether, and one of them was spoiled by an accident. A challenge cup has never been won under such conditions before. It has, however, to be won twice consecutively, or three times altogether, to be permanently retained. It is given by the Hull Amateur Floral and Horticultural Society.

PLANTS.—We can only say as regards what are known as "specimen" plants that those exhibited were with few exceptions very far below the average standard of merit, the best—and some of them were healthy and well flowered—being exhibited by Messrs. Wood, Bulmer, Raby, and Tall. All the best were trained without twisting the stems, the few where dwarfing was attempted being tied down too closely and too late. The bending should be done at the lower part of the stems, so that the twisting is obscured by the foliage above—i.e., of the shoots bearing the blooms; tying down the stems just under the flowers being a great mistake almost invariably made by the inexperienced—hence this hint.

Far more commendable and decidedly effective were groups of Chrysanthemums interspersed with foliage plants arranged for effect in a space of 100 square feet. In addition to the first prize of £5, a framed oil painting of Chrysanthemums of the same value was offered to the winner by Mr. J. F. Norton, artist, Hull. There were five competitors, and right well did they contribute. The premier position was secured by Mr. H. Bulmer for a very bright and effective arrangement, chiefly of Chrysanthemums of excellent quality both as regards blooms and foliage, and the colours well associated. They were relieved with light touches of slender Palms and Dracenas up to a central plant of Cocos Weddelliana next the wall, and 9 or 10 feet above the floor. The semicircular group was finished with Crotons, Dracenas, and other dwarf ornamental plants margined with Panicums and Ferns. The effect was rich, yet not devoid of elegance by the admirable balance of the whole, and an absence of extreme packing and overcrowding. The second prize group of Mr. Graham, gardener to George Lawson, Esq., Newland Grove, Hull, was also of considerable merit, and, in fact, very nearly equal to the other. Mr. G. Cottam, Anlaby Gardens, was awarded the third prize with a smooth showy arrangement, but rather heavy towards the edge; and Mr. Howell, gardener to Lieut.-Col. Saner, the fourth for a mass of flowers rising to 10 or 12 feet high, and a few Palms interspersed. Another group was too "sticky" and formal, the remaining one free and elegant but somewhat lacking in diversity. The several groups contributed powerfully to the general effect, were of the right kind for the building, and it is a question worthy of consideration as to whether smaller groups should not be encouraged as well.

An extensive and excellent miscellaneous collection of plants was admirably arranged by Mr. E. P. Dixon, not for competition, and Messrs. Martin and Son had a very attractive display. Admirable collections of fruit were contributed by Messrs. James Dickson & Sons, Chester, and Messrs. Richard Smith & Co., Worcester; and Messrs. Cannell's stands of single Chrysanthemums and Zonal Pelargoniums were greatly admired by the great concourse of visitors, of whom nearly 7000 attended the Show.

The directors of the Hull Chrysanthemum Society are to be congratulated on what they have accomplished, and they deserve all the support that can be accorded them in furtherance of their object—the superior culture of Chrysanthemums among all classes of society.

WINCHESTER.—NOVEMBER 17TH AND 18TH.

THE third annual Chrysanthemum Exhibition was held in Winchester on November 17th and 18th, in the Guildhall, a building well adapted for such a purpose. The Show was a decided advance on its predecessors as regards quality and general excellence of cut blooms and plants. The two most noticeable features were the grand blooms exhibited by Mr. E. Molyneux, gardener to W. H. Myers, Esq., Swanmore Park, Bishop's Waltham. The specimen plants shown by Mr. Joy, Shirley, Southampton, were a fine example of cultural skill. The plants, fourteen in number, averaged about 5 feet in diameter, splendidly flowered, with good foliage; in fact, we have not seen better this year. Mr. Neville, gardener to Mr. Flight, Cornstiles, Twyford, staged a good group of Chrysanthemums, well arranged in a half circle, devoid of that flat formal style often seen in Chrysanthemum groups. His cut blooms were above the average quality. Fruit were not shown in large quantities. Vegetables were very good and above the average. Much praise was gained by the Hon. Secs., Mr. R. Porter and Mr. John B. Colson, for the way in which they managed the Exhibition.

The following is a list of the principal prizewinners:—Twenty-four cut blooms, distinct, sixteen incurved or reflexed and eight Japanese.—Five competed in this class, but it was an easy victory for Mr. E. Molyneux, gardener to W. H. Myers, Esq. The following is the list read from left to right:—Back row—Madame C. Audiguier, J. Delaux, Fair Maid of Guernsey, Boule d'Or, Belle Paule, good; Thunberg, Meg Merrilees, fine. Middle row—Lord Leicester, grand; Hero of Stoke Newington, Queen of England, fine; Emily Dale, Empress of India, Princess of Wales, Golden Empress, good. Front row—Prince Alfred, Princess of Teck, Mr. Howe, Cherub, Lord Wolseley, Lady Carey, a fine bloom. Mr. Neville, gardener to Mr. Flight, Cornstiles, Twyford, came second with even blooms of incurved, the Japanese being rather small. Third Mr. W. Pope, gardener to the Earl of Carnarvon, Highclere Castle, Newbury. Twenty-four cut blooms, not less than eighteen varieties.—Mr. Molyneux was again first, Mr. Neville second, and Mr. Pope third. For twelve cut blooms, incurved, Mr. Molyneux was also first, Mr. Neville second, and Mr. A. Bridger, gardener to Colonel Martin, Flectlands, Fareham, third. For twelve cut blooms, reflexed, not less than eight varieties, Mr. Molyneux was decidedly ahead with fine blooms of Golden Christine, Dr. Sharp, Pink Christine, and Mdle. Madeline Tezier. Twelve cut blooms, not less than eight varieties.—First Mr. Trinder, gardener to Sir Henry Mildmay, Bart., Dogmersfield Park, with clean even blooms. Second Mr. L. Jennings, gardener to J. Freeman, Esq., Forest Lodge, Farnborough, and Mr. A. Bridger third. In the class for twelve cut blooms, not less than eight varieties, for those who never won a prize for Chrysanthemums, the prizewinners were Messrs. Trinder; A. C. Smith, Havant; and J. Wareham, gardener to Mrs. T. Gunner, Heathfield, Winchester.

The best six double Primulas were from Mr. T. Hunt, gardener to Mrs. Warner, Northlands, Winchester. The best six berried plants from Mr. E. Astridge, gardener to W. Barrow Simonds, Esq., Abbots Barton, Winchester, and the best six dinner table plants from Mr. Molyneux.

Grapes were well shown by Mr. Molyneux; Mr. James Clark, Westwood, Wilton, Salisbury; Mr. G. Mildon, gardener to Mrs. Turner, King's Worthy; Mr. C. Warden. The leading collection of fruit, not less than six dishes, came from Mr. A. C. Smith, Havant, Apples and Pears being well shown by Mr. L. Jennings; Mr. J. T. Philpott, gardener to Mrs. Cornish Browne, Twyford Lodge; and the Rev. C. Wickham, Compton. For collection of vegetables, eight varieties, Mr. R. Lye, Sydmonton Court, Newbury, was first, the competition being very close. Mr. Pope was a good second, and the third place was taken by the Very Rev. the Dean, The Deanery, Winchester.

For best group of miscellaneous plants, arranged for effect (not open to nurserymen), first, J. E. Axford. The arrangement of this group was very good, though rather too much packed in the cotton.

For the best collection of Chrysanthemums grown in pots, arranged in a space 8 feet by 6 feet, quality and general effect to be the leading features, the group staged by Mr. Neville was remarkable for size and quality of flowers, the most noticeable being Comte de Germiny, Mdle. Lacroix, Album Plenum, and M. Tarin. Mr. A. Prouting, gardener to Miss Butler, St. Thomas Street, Winchester, was a good second. Mr. Joy staged grand specimens of six plants, single stems, distinct varieties, 5 feet in diameter. Here Mr. Joy had six grand plants of Japanese, some of the finest we have seen this year, the average size 5 feet in diameter, with fine foliage and splendidly flowered, of the following varieties:—Bouquet Fait, Album Plenum, Peter the Great, Hiver Fleuri, Madame Bertie, Rendatler, and Fair Maid of Guernsey. Other prizes were taken by Miss Butler, Mr. Joy, and Lady Waterhouse. For the most tastefully arranged single stand of Chrysanthemum cut blooms and foliage suitable for table decoration, Miss Bessie Flight took the first place with a very tasteful stand. For the most tastefully arranged single stand of cut hardy shrubs, Ferns, and Grasses (grown out of doors) suitable for table decoration, first, Miss Flight, Cornstiles, Twyford, with a beautiful and well arranged stand, and Miss Bessie Flight second.

SHEFFIELD.—NOVEMBER 20TH AND 21ST.

THE first Exhibition of the Sheffield and West Riding Chrysanthemum Society was held on the dates named in the Corn Exchange—a very capacious and well-lighted building, admirably adapted for a large show. The Show under notice was not large, so far as it was composed, at least, of the products arranged in competition for the prizes, but an extraordinary display composed of Conifers, greenhouse Rhododendrons, Orchids, and various other plants from the nurseries of Fisher, Son, & Sibray, assisted to furnish the huge building in a most satisfactory manner. It is impossible to speak too highly of the consignment from Handsworth, for assuredly such an extensive and varied collection of hardy and tender plants is rarely seen at a public exhibition.

The objects of the Sheffield and West Riding Chrysanthemum Society are concisely stated in the rules thus:—"It shall have for its objects the promoting and improving the cultivation of the flower—firstly, by holding periodical meetings in March, May, August, and December, at which meet-

ings essays shall be read and discussions initiated upon the best modes of cultivation; and, secondly, by holding annually in November, in some convenient public building, an exhibition of the flower, at which open classes shall be provided, and all classes of exhibitors be allowed to compete for the prizes to be offered." And further, it is reasonably stipulated that "All exhibitors in the open classes, not being members of the Society, shall, on being paid their prize money, have 5 per cent. deducted therefrom as entrance fee to such classes. Patrons and members shall be free to all classes." The Society has for its President Mark Firth, Esq., the worthy inheritor of an honoured name, an influential body of patrons, and a practical Committee, with Mr. J. Walker as Chairman and Mr. W. K. Woodcock as Secretary.

The schedule was a modest one, being composed of nineteen classes, five of them open to all, even for district gardeners, three for amateurs, and a similar number for cottagers.

The chief prizes in the open class were £5 for a group of Chrysanthemums and other plants, £5 for twenty-four incurved Chrysanthemum blooms distinct, and a similar amount for the same number of Japanese blooms, with graduated amounts for second and third prizes. The method of dividing the two sections of cut blooms appears good, as the same exhibitor can stage in both and win both if his flowers are the best, and so secure the £10, while both the incurved and Japanese blooms can be judged on their merits in each case, instead of having to strike an average between a good stand of one and an inferior stand of the other, a by no means impossible contingency.

In the first open class—a group of Chrysanthemums interspersed with foliage plants arranged for effect, on a space of 100 square feet—the chief prize was won by Mr. W. K. Woodcock with excellently grown plants tastefully disposed, the centre a Cordylus with Palms, Pandanus, &c., associated with large-flowering and Pompon Chrysanthemums margined with Ferns. Mr. Walker, gardener to B. P. Broomhead, Esq., followed, his group including some well-grown and trained specimens, to one of which the National Chrysanthemum Society's medal was awarded as being the best plant in the Show. The same exhibitor secured the first prize for six trained specimens with fresh and good examples, followed by Mr. Woodcock. In the open class for twenty-four incurved blooms, distinct, the first prize was well won by Mr. H. Broomhead, an amateur cultivator, with uniformly neat solid examples of medium size, and, with two or three exceptions, very fresh. Mr. G. Mease, The Gardens, Victoria House, Dunkinfield, was second with an unequal stand, some of the blooms large, others small and rather rough. The third prize fell to Mr. J. Walker with generally neat and clean, but half a dozen small, examples and about the same number somewhat rough; still, the competition was extremely close. The National Society's medal was won by Mr. Mease with a well-finished medium-sized flower of Golden Empress as the best bloom in the Show. In the corresponding class of twenty-four Japanese blooms, Mr. G. Mease was first with a very good stand indeed, in which Belle Paule, Japonais, and Val d'Andorre were conspicuous by their merit. Mr. H. Broomhead was second, having, among others, fine examples of Criterion and Comte de Germiny, and Mr. Woodcock third.

In the district class of twelve incurved blooms Mr. Wainwright was placed first with wonderfully fresh and clean examples with broad petals, but a week too young. The same remark applies to the second-prize flowers of Mr. Woodcock, which had not had time to develop or "fill up," third Mr. Walker. The prizes in the corresponding class fell in the same order, but Mr. Woodcock pressed his leader more closely, staging Flamme du Punch in brilliant condition. British Ferns are well grown in the neighbourhood of Sheffield, and good prizes were offered for thirty-six plants arranged for "effect." Following the conditions of the schedule, the prizes were awarded to Messrs. Newsham, Davey, and Eadon in the order named. Had the prize been offered for the best plants, Mr. Eadon would have been first instead of last; if for the choicest variety Mr. Davey would have had the premier position. It can only be said that all the collections were meritorious, but the greatest taste in arrangement was displayed by Mr. Newsham and the best "effect" produced by his plants. This, after a long and close examination, was the unanimous verdict of the Judges, though it is not at all unlikely it might cause a little surprise. Prizes were offered for Grapes, the best black bunches being staged by Mr. Holland, gardener to D. Gilmour, Esq., very good indeed, followed by Messrs. Collier and Wainwright; Mr. Whitely, gardener to Thos. Jessop, Esq., being the only exhibitor of white Grapes.

Wonderfully neat and well-finished incurved Chrysanthemums were extensively staged in the amateurs' and cottagers' section; indeed, there was a smartness about the blooms that was to a great extent lacking in the larger classes. Mr. Udale exhibited his blooms, not for competition, that had been successful a few days previously at Burton-on-Trent, and the incurved flowers were the best in the Exhibition; they were highly commended, and similar marks of approval were accorded for a fine Cypripedium exhibited by Mr. Pidsey, and a good specimen of Asparagus plumosus by Mr. J. B. Hague; also for attractive groups of plants arranged by John Eaton, Esq., and Mr. Seagrave, while the gigantic contribution from Handsworth was commended in the highest possible terms as being especially meritorious.

VENIDIUM CALENDULACEUM:

THE specific name of this plant is so far appropriate that some may suspect it to be an old acquaintance, but although it certainly resembles in colour and form some of the Marigolds, botanically it is sufficiently distinct. In the Calendulas, of which the common Marigold may be taken as a type, the involucre surrounding the flower head is composed of many narrow, pointed, erect leaflets, nearly equal in size, and arranged in one series. In the genus Venidium the scales of the involucre are of two kinds: those composing the innermost series immediately next the florets of the ray are of an oval form, with a thin transparent colourless margin; external to these are several rows of imbricated scales of a

narrower form, and covered with shaggy hairs, especially at the tip, which is reflexed.

The seed is also of a different structure to that of the *Calendulas*, as the accompanying figure will show. The *Venidiums* are more closely allied to the old genus *Arctotis*, with which some of them were formerly incorporated; but in *Arctotis* the seeds are furnished with a chaffy pappus, an appendage which appears to be wanting in *Venidium*.

The present species is a dwarf annual plant, not often exceeding, even when in flower, 5 or 6 inches in height; the radical leaves are of a broadly ovate, almost orbicular form, with a sinuate margin, and long foot-stalks more or less winged at their edge; the whole leaf, but especially its margin, nerves, and petiole, being clothed with long white, clammy, spreading hairs. The leaves at the base of the flower stalk are of a similar form, but rather narrower, and have their petioles more winged; those higher up are sessile, becoming more pointed as they approach the flower.

The blossoms are produced singly, of which each plant yields a cor-

Fig. 73.—*Venidium Calendulaceum*.

siderable number. As those which spring directly from the root fade, others are developed from the axils of the stem leaves.

The circumference of the flower head is composed of about fifteen to twenty strap-shaped florets, arranged in a single series and of a fine light orange colour; they bear no stamens, but only a short style terminated by a stigma, divided into two broad black lobes. The florets of the disc, or central portion of the flower, are tubular, and contain both stamens and style. Before the tubes open the disc is green, but as they expand it assumes a blackish purple tint, which is due to the black tips of the segments of the florets. The character of the scales of the involucre has already been explained, as well as the absence of the pappus, so peculiar to most Composite plants. The receptacle on which the florets are seated is slightly pitted, but otherwise quite smooth, or naked as it is termed in botanical parlance. When fully expanded the flowers are about $1\frac{1}{2}$ inch in diameter. They will open in diffused light, but usually close about two o'clock.

Venidium calendulaceum requires the treatment of most other half-hardy annuals, such as *Zinnias*, *Stocks*, *Asters*, &c. There are several other species, chiefly of perennial duration. All of them, as well as the present plant, are natives of the Cape of Good Hope.—T.

JOHN DOWNIE GRAPE.

My opinions are not in "touch" with those of Mr. McIndoe when he thinks it "odd" that I should not have reported my experience with this Grape last year instead of this season. I think it would be well if

cultivators always took longer time to praise or censure the merits of new horticultural products than the first season in which they have had trial of them. Most of us know well what material changes often take place when a fruit or flower has been grown a few seasons, especially when circumstances may have been untoward, or *vice versa*. Some striking illustrations are before us while we write. *Gros Maroc*, which has grown extra fine in berry with us, but with flavour little better than I have tasted it elsewhere. Last year the berries were oblong and somewhat hammered; this season they are as round and smooth as ever I saw Grapes.

I have every confidence in the integrity of Messrs. Dunn and Downie, and believe it is possible that the Grape to which reference is made may have been sent inadvertently instead of the *bonâ fide* one. I had my Vine sent gratis with the express wish that I would test the fruit in our new vineries.—M. TEMPLE.

WORK FOR THE WEEK.

KITCHEN GARDEN.

MUSHROOMS.—We do not attempt to grow these all the year round. When vegetables are plentiful they are not much valued in summer, and as autumn comes on we generally gather a large quantity in the park; but now and during the entire winter the house Mushrooms are in great demand, and we try our best to have them daily from the end of October until April. At present we have them unusually good, and this we attribute in a great measure to the excellency of the spawn. Without first-rate spawn abundance of the best Mushrooms will never be produced. The utmost care should be exercised by seedsmen to have this good, and no one should buy any but genuine bricks. The whole crop depends on the quality of them. We have known much labour thrown away and material lost by working with bad spawn. Just now one of our best beds is in the potting shed. It is a lean-to house with a bench in front, a pathway in the middle, and a pot bin at the back, and it is here the bed is formed and the Mushrooms are coming in hundreds. This bed began to bear five weeks after spawning, and others which have been added to it for a succession promise to be equally quick and sure. We exclude light and keep off cold draughts by covering them with a thick coating of hay. We have tried the open-air culture, but prefer this simple shed plan in winter. The Mushrooms are much finer and more of them than when cultivated in a specially heated Mushroom house. More beds should be formed to bear in January and February. The produce will be very acceptable then, as vegetables will be scarce. Have the manure moderately well dried and spawn and soil it before the temperature falls below 85°. When the manure is in good condition we spawn on the same day as the bed is formed, and soil over immediately afterwards. Beds which have been bearing for some time should have a good soaking of manure water heated to 90°. That from the cow sheds or manure is excellent. Cover with hay immediately, and a strong abundant second crop will soon appear.

MUSTARD AND CRESS.—As other salad plants become scarce these will be more wanted, and weekly sowings should be made. We use shallow boxes, 15 inches wide and 3 feet in length, for sowing in at this season. Rich soil is put in to the depth of 2 inches or 3 inches, and the seed is simply put on the surface and the box placed in a warm house. By sowing one or two boxes a week a constant succession may be kept up, and as a box may be stood here and there in any odd corner the expense of culture is not great.

BETROOT AND CARROTS.—Where taking up these useful roots has been delayed, no time should now be lost in getting them under cover. The Carrots will stand much frost, although it does not benefit them, but the Beet is very easily injured, and one sharp frosty night may ruin an unprotected crop.

HEELING BROCCOLI.—Those which have formed small heads or about to fruit should be lifted with a good ball of soil to the roots, and be laid in close together in trenches facing the north. This retards them from coming all in at once, and it also protects them greatly, especially if their position is a sheltered one. They are also easily protected in very severe weather, as, being laid in close together, the whole can be covered over with mats, bracken, or straw.

CHICORY.—We have just lifted a quantity of roots of this and planted them in 10-inch pots. Probably before this is in print they will have been placed in a semi-dark place under the stage of a warm pit, and here they will soon grow and produce a large quantity of excellent salad material. Where there are plenty of roots forcing is easily done, and with plenty of Chicory and Mustard and Cress there will be no scarcity of salads in winter.

FORCING.—Continue to introduce Asparagus roots. Growth will be rapid and certain with a bottom heat of 85°. When kept near the glass the heads will always be robust and excellent in flavour. Cover more Rhubarb and Seakale; both will be in at Christmas if attended to at once. Lift and pot a quantity of Mint and Tarragon roots. Place them in a temperature of 70°, and the tops will soon be large enough to gather.

WHEELING MANURE.—Digging and trenching should now be the standing orders for all favourable opportunities of advancing kitchen

garden work. Where the quarters are vacant it is a mistake to allow such operations to stand over until spring.

FRUIT FORCING.

FIGS.—Early-forced Trees.—If the house is still open it should now be closed, and before any attempt is made to excite the trees the roots should be repeatedly watered with tepid water until the soil is thoroughly moistened. Although the Fig may be started at a high temperature, the most satisfactory results are obtained where the houses are closed early, and the roots and fruit are allowed to advance steadily under the influence of moist and genial heat from fermenting materials placed in near proximity to the pots. Oak or Beech leaves being used, they should be worked and fermented before they are introduced, and for some time afterwards they can be watched and allowed to lie loosely, until the heat declines to 70° or 75°, which must be the maximum about the roots or pots. The night temperature may range from 50° to 55°, with a rise of 5° to 10° by day, when a little ventilation at the top of the house will allow the vitiated air to escape. The trees will require syringing with tepid water two or three times a day, and moisture must be secured at night by damping the floor at 8 or 9 P.M., when the conditions outside favour the rapid escape or condensation of moisture at this changeable season. A little fire heat will be necessary to maintain the temperature required, but it is advisable to keep the temperature down in cold weather, and accelerate growth at a later period, when the weather is more favourable.

Succession Houses.—Take advantage of wet days for getting succession houses ready for starting when the proper time arrives. In the case of trees in pots, take care that the roots do not become too dry during the season of rest. When the tree are planted out in borders the danger is easily met, as the roots can be watered if necessary, and well mulched with manure after they are cleaned and tied to the trellis.

Fig trees in unheated houses should be loosened from the wires and be drawn from the lower part of the wall, and be protected with a little dry straw or fern, so as to save them from injury in case of severe frost.

CUCUMBERS.—In consequence of maintaining a moderately high temperature the moisture has had to be increased, and as the parching influence of highly heated pipes is injurious, hence the covering of the house at night with mats is not only a means of economising fuel, but secures a more genial atmosphere and equable temperature than can otherwise be obtained. Cucumbers when swelling their fruits like liberal treatment, hence copious supplies of tepid diluted liquid manure should be given as necessary. Plants that have plenty of roots and are making growth freely will take copious supplies; indeed there is no fear of over-watering provided the drainage is perfect and the bottom heat is maintained at 80° to 85°. Remove the male flowers as they show, reserving a sufficient number for setting purposes; avoid overcropping, and do not stop very closely for the next few weeks, but avoid overcrowding, and maintaining a successional growth, so as to secure a succession of fruit. The night temperature should range from 60° to 65° when the weather is severe, and 5° more on mid nights, the day temperature 70° to 75°, and an advance of 5° to 10° from sun heat.

STRAWBERRIES IN POTS.—Since our last calendar under this head was written the temperature has fallen to 20°, and though the plants have not had any protection, it is well to have a supply of dry soft straw or bracken at hand, ready to scatter over the plants when the weather is severe. It should remain over the plants so long as they are frozen, but removed whenever the weather is mild. In severe weather the roots are frequently displaced by its action, and when the thaw comes a derangement of drainage ensues if they do not settle into their proper places, which should be seen to and rectified. It is important, as the forcing season is upon us, to have a number of plants at all times in readiness to be prepared previous to introducing them into the forcing-houses to succeed those that are already started. The beginning of next month is soon enough to start early varieties, which are to afford ripe fruit early in March next, but it is well to afford time for the plants to be forwarded gently in the early stages; indeed, slow forcing is the great secret in early Strawberry growing, and, except where there is a pressing demand for early fruit, or the plants are in fine condition for starting, it is better to defer forcing large quantities until the new year.

Plants in bearing and advanced for ripening will require increased vigilance to keep the fruit from damping; indeed, watering should be done only on the morning of fine days, when ventilation can be given to dry up the atmosphere before night, and in foggy damp weather great care will be necessary where fruits are ripening.

THE BEE-KEEPER.

NOTES ON BEES.

WAX EXTRACTOR.

No one who has been accustomed to melt down his combs, and so extract the wax by the patience-trying method commonly used in many districts, can form any conception of the practical benefit, both in saving of time and of wax, accruing from the use of an extractor. To me no process was more obnoxious than the reduction of old comb to wax—now it is a pleasure. No comb is so old as not to yield some

wax, and by this simple machine the blackest as well as the whitest comb yields its full modicum of wax alike easily and well. It is true that it is necessary to run it through more than once, but for my own part I think that when once the wax is obtained quite clear from bee-bread, honey, brood, and all other foreign substances, boiling down in a little clear water gives the best result. The wax-extractor has often been described, and can be seen in any of the catalogues of dealers, but it may not be useless to give some idea of its construction, which is not very elaborate. It consists of an outer tin cylinder having a dish inside communicating with an outlet, through which the wax as it is melted runs into the vessel placed for its reception. Between this dish and the outer cylinder there is a space to allow the steam to pass up. About an inch from the bottom of the dish a perforated tin basket is placed, supported on three pieces of metal. The perforated cylinder is of course of a size rather smaller than the dish, as otherwise the wax would trickle down into the water and so cause no little trouble and loss. When it is intended to use the machine the perforated cylinder must be filled with the comb it is desired to extract from, and the whole apparatus placed on a pan of boiling water and put on the fire. The outer tin and the saucepan ought to fit as closely as possible in order to retain all the steam and so facilitate the operation. Those who have an eye to their own interests will have a saucepan made which, while doing duty as a boiler for the extractor, will also be useful for making syrup or any other necessary which requires the aid of a fire. If they already have such a pan then they will adapt the wax machine to the pan and so save some little expense; but one thing is very necessary, and that is not to get an extractor of less dimensions than a foot deep by 8 or 9 inches across for the perforated cylinder, the rest of course being in proper proportion.

HONEY BOTTLES.

These are still somewhat high in price, so that bee-keepers are under a disadvantage in this respect. The kind of thing required is a receptacle at once cheap, neat, and pretty; and although I have never made the suggestion to any dealer in appliances, it has often occurred to me that a flower vase of elegant construction, yet simple, might be produced at a rate as cheap, if not cheaper, than the bottles now so commonly used; and if such a production could be obtained many who now regard the price of the bottle as a great drawback would think much less of money spent in buying one article which would really obtain two—that is to say, honey in a pretty glass, and after the honey is used an elegant flower vase.

RACES OF BEES.

The most interesting article I have read for many weeks was one in the issue of 20th August last—"Notes on Bees." It was instructive and amusing, and I had ventured to hope that a table showing the result for the year from stocks of the different kinds of bees there mentioned might have appeared in print; if such a table could be given it would be of immense advantage, as by comparison some little idea could be formed of the honey-gathering powers of English and alien bees; as several kinds being in one apiary, each one probably with the same advantages, attended with the same master hand, a good field for observation is afforded. The concluding part of the article was indeed a dreadful tale of bad temper on the part of the bees. Now I often have a stock myself which, though to all appearances similar as regards its bees to the rest, shows unmistakeable signs of wicked spirit. Stinging whenever anyone approaches it makes all operations in the apiary anything but pleasant. Sometimes I fancy it is caused by a chance cross of the queen, for all manipulations are carried out with studied quietness. Never yet have I succeeded in curing such a stock. "Dummies" have been tried, and such other means as have from time to time suggested themselves to my mind, but with little good. Is there any cure for bees which, whenever approached, seem to think it the great object to see which can be the first to implant a

sting in the most tender part of the wretch who dares to approach within five yards of their hive? If anyone can throw out a suggestion it shall have a good trial next spring, for, unluckily, winter never effects the slightest change, as some people whom I have met with imagine it may do.

COTTAGE BEE-KEEPERS.

Is this class of bee-keepers gradually increasing or dying out? For my own part I am quite uncertain whether the strides made of late by modern bee-keepers have conduced so much to an improvement in cottage bee-keeping. The bar-frame and other appliances seem to have so changed the order of things appertaining to bee-keeping that, instead of cottagers getting the benefit of the change, others have stepped in, and to some extent subverted the very class to whom bees ought to be a means of getting increased comfort and pleasure. Simplicity is dying, sacrificed at the altar of Trade! Myself—by necessity a small bee-keeper only—away from home from early morning till late in the evening, I can keep but few stocks, and these must be managed upon a simple method not requiring too much time and attention. So, too, the labourer. A few stocks are all that he can manage, and as for spreading brood and all such delicate manipulations, they appear to him to be quite out of his sphere. I sympathise with the cottager in his efforts to assist himself, and always advise him to follow the method requiring least time and attention, provided such system gives a good yield of honey without destroying the bees. In doing so he always has my best wishes, and any assistance it is in my power to give he may claim without hesitation, and I feel sure that others too—and more able—will give his position their most careful consideration.—FELIX.

GENERAL MANAGEMENT OF BEES.

FEEDING.

THERE is one phase of feeding absolutely necessary if safe wintering is to be expected. The pollen or honey has a tendency to cause abdominal distension, and bees from certain moors, and before the winter is far advanced, are often swelled to an enormous extent, and show signs of distress, not from dysenteric symptoms, but constipation. That some kinds of Heather have this effect where there is little pollen I have long since proved, but the most serious cases are always those that have much pollen. To avert any calamity from this cause, whenever the bees are brought from the Heather a portion of their honey should be removed and sugar given instead, as much as will tide the bees over till January, when all danger will be past. Although bees having nothing but sugar in store to feed from are mostly healthy and free from disease, still there is nothing like the produce from Heather for breeding purposes; while the fact that bees are healthy on sugar alone throughout the winter negatives the assertion that bees require pollen to restore waste of tissue.

Dysenteric distension is mainly due to cold through draughts or damp. Watery honey, which has fermented and become acid, also brings about that disease. Bees have the power of changing a full stomach of honey into carbonic acid and water in a very short time after it has been swallowed, and if an airing cannot be had death ensues. A very slight disturbance during the winter months causes bees to fill themselves, resulting as above. I may now ask the question, How can a hive be opened and the quilt turned up without bringing about these results? If you wish your bees to be strong and healthy never touch them during winter.

MANIPULATING.

That the ferocity of bees is greater now than when we had the one variety only there can be no doubt, and bee-keepers who were adepts in handling the old black bee are cowards with the new varieties and their crosses, the Carniolians excepted. The first things the bee-keeper should learn are the sounds of the bees. Many a person rouses docile bees to fury, and gets severely stung by not understanding these sounds, treating well-disposed bees as if they were vicious, causing through some rash act quiet bees to become spiteful.

CARBOLIC ACID.

This is the best of all quieters except honey, and may be used in all cases of manipulation, for disinfecting, medicating water, and syrup; but after many years' experience I have not found it a thorough eradicator of disease, but a capital preventive. If bees are tardy in swarming and ready for it a little tow saturated with the acid

and placed at the side of the entrance prevents lying out and brings the swarm away. When bees are inclined to bive in an inaccessible place a little carbolic acid prevents their entering, and will dislodge them if a feather can be inserted in the crevice. Some feathers saturated and held beneath the swarm will dislodge and cause them to take to a hive held over them. A little acid judiciously used helps to prevent robbing and clears supers and hives of bees, and where a piece of excluder zinc is used catches the queen, while there is nothing better than carbolic acid for preventing a swarm entering an already tenanted hive. As carbolic acid prevents incipient disease and does not injure the contents of the hive like smoke it is indispensable in the apiary.

CATCHING SWARMS.

Bees are at all times liable to fly a long distance at swarming time, or take to some lofty tree not easily got at, often where cutting the bough would spoil the tree. To take a swarm from such places I use rods similar to those a sweep employs for sweeping chimneys. On the top there is a small pulley, over which a cord runs to lower or raise the light box intended to catch the swarm. Mr. Langstroth uses a "bee bob," which doubtless attracts bees, but if bee-keepers would be honest and deliver up to the owner any swarm which might come his way there is nothing better than a combed but tenantless hive standing near the apiary and in the densest part of it. Bees have a special liking for hollow trees, to which they enter through a small crevice (no alighting board). A rough box placed in the shady part of the garden, in which another box is placed inside furnished with a piece of comb, and the outside of the outer box covered with cork, having a slit or opening through which the bees might enter to the inner box, makes a capital decoy for stray swarms, which may be transferred from this box to their permanent hives. This should be such as to have always a uniform degree of temperature, and the outside should have no angles or any fillets or binders, &c., that will hold or draw damp. Any hive that does so is a defective hive.

For straw hives I never found anything better than a straw hackle plaited to a card, reaching to the turning of the crown, and completely overlapping the floor from which the alighting board ought to be detachable, and separate an eighth of an inch or so from the floor proper. The best of all floors are those of perforated zinc. On the crown of the bive and above the hackle some dried grass should be laid over a cone of some waterproof material, having a ventilator at the top, unless provision has been made for this under the eaves of the cone. The best form for a hive is the narrow and high one of the Stewarton type. Where dividing boards are used provision should be made for easy withdrawal. A very good plan is to have it made in two pieces, joining in the middle. A tongue and groove effect this, which should not be less than 2 inches deep. On the upper edge of divider there should be a piece of wood tongued into it, and nailed firm to the one half, while the other must be left free. A mortice or two should be cut like a bar of a door, through which nails pass into the other half of divider. A wedge in the middle keeps it distended; withdraw the wedge, then a slight push on the end of the dividing board will give sufficient slack, and the whole depth to remove without jar or killing bees.

Bee-keepers cannot be too deeply impressed with the necessity of having their hives made so that they are easily moved about. The majority of hives made are by far too unwieldy for that purpose, while their great size does not give them sufficient internal dimensions for profitable bee-keeping. Dale or Clover honey has but a very limited sale, but there is always a great demand for Heather honey, and at a bigger price too; therefore it is obvious that bee-keepers will exert themselves more than they have done to obtain a full harvest of Heather comb. To obtain this satisfactorily the hive must be light and easily moved about; and I cannot point to a better form than the "best hive in creation." Other points will be described on a future occasion.—A LANARKSHIRE BEE-KEEPER.

* * All correspondence should be directed either to "THE EDITOR" or to "THE PUBLISHER." Letters addressed to Dr. Hogg or members of the staff often remain unopened unavoidably. We request that no one will write privately to any of our correspondents, as doing so subjects them to unjustifiable trouble and expense.

Correspondents should not mix up on the same sheet questions relating to Gardening and those on Bee subjects, and should never send more than two or three questions at once. All articles intended for insertion should be written on one side of the paper only. We cannot reply to questions through the post, and we do not undertake to return rejected communications.

Fungus on Chrysanthemum Leaves (C. H. M. Sheffield).—We have submitted the leaves to an experienced fungologist, who states that the nodules on the leaves are "the sporangia of *Pilobolus crystallinus*, and proceed from the dung on the surface of the soil; the leaf is not diseased."

Transplanting Box (H. R.).—Box may be taken up and fresh edgings made now, or at any time when the weather is mild and the soil in free working condition. We have formed Box edgings with equal success in November and March. If the portions divided and planted have roots we have no choice as to autumn or spring planting, but prefer forming lines of rootless slips in October. More depends, however, on the way in which the work is done than on any particular time between September and April for doing it.

Laying down Old Laurels (Idem).—There is no better time than the present for thinning out and pegging down the tall stems of Laurels. We mention thinning, because it is often difficult and also undesirable to peg them all down. When the stems are very strong it is necessary to chop them with a long slanting cut near the base and sufficiently deep to enable them to be bent flat down, a very strong peg or two being driven in not far from the bend to keep them in position, as it is not sufficient to merely peg down the tips and leave other parts of the stem bent in the form of a bow a foot, more or less, above the surface. That indicates bad workmanship, and, besides, the shrubs so treated do not usually grow well.

Laburnums for Towns (A. S.).—We think you have been misinformed. Laburnums grow freely and flower beautifully in the suburbs of London, also in the metropolitan parks. We also remember seeing a tree planted in an area between Hyde Park and Victoria Station, its branches being trained up the wall and round a balcony, and they were covered with golden racemes. So far, then, from our confirming what you have been told, that "Laburnums will not do well near towns," we regard them as good town and suburban trees so far as regards their growth; but it should be remembered the seeds are poisonous.

Passiflora Buonaparteae.—Mushroom Spawn (*Constant Reader, Bournemouth*).—The plant from which the engraving you refer to was prepared was obtained from Messrs. Veitch & Sons of Chelsea, and we have no doubt that you will be able to get as many plants as you require either there or at Mr. B. S. Williams, the Paradise Nursery, Upper Holloway, as all advertise it in their catalogues. The quantity of Mushroom spawn required to spawn three beds, each 12 feet long and 18 inches wide, would be exactly a bushel, or twelve bricks. As a guide to the quantity required and to the distance apart at which it should be inserted in the bed, we may mention that one brick should be divided into eight parts, and each of the latter inserted in the bed at 9 inches apart. If you are inexperienced in Mushroom culture, obtain "Mushrooms for the Million," price 1s., published at this office. In this you will find all the information you need on this subject.

White Grape for Cool House (W. A.).—It is extremely unlikely that you would find the Golden Hamburgh as satisfactory as the Golden Queen. It is earlier but not such a good grower, bearer, nor "setter," while its quality is only second rate. You are far more likely to succeed with Foster's Seedling, which grows and bears well, and the fruit, though not large, is of better quality than the Golden Hamburgh, and does not crack under even fairly good management. Taking all its properties into consideration Foster's Seedling is the best white Grape for growing with Black Hamburghs in a house where little fire heat is employed, and the fruit does not split except the house is kept too close and damp. A rather dry and buoyant atmosphere should be maintained during the ripening period, and at that time a little fire heat with judicious ventilation is often of great service to both this and the Black Hamburgh Grape.

Exhibiting Plants (C. H.).—In a class of "six miscellaneous plants, three in and three out of flower, distinct varieties," we consider that six plants and no more are eligible for prizes, and if we were judging in such a class and any exhibitor made up a pot of "five varieties of *Oncidium* grown on blocks, and placed together in a large pot and shown as one plant," we should at once have disqualified the collection. In such a class we consider the "made-up" mass inadmissible on two grounds—an excess both in the number of plants and of varieties. It appears the more strange that this packing should have been allowed, since in former years *Poinsettias* and *Enphorbias* have been disqualified because there was more than one plant in a pot. In the class to which you refer there were, if you are correct in your statement, ten plants shown instead of six, and that appears to us quite conclusive as to the ineligibility of the plants in question for recognition by the judges.

Anthurium crystallinum (Querist).—This is a stove plant, and succeeds best in a house where the temperature seldom falls below 65°. When making its growth it enjoys a temperature from 70° to 90° with a moist atmosphere and a shaded position, dry air, sharp currents, and much sun being injurious. It requires a very rough open compost, such as lumps of peat, loam, charcoal, and sphagnum moss, the pots to be well drained and the plants elevated above the rims, somewhat as in potting *Orchids*. Abundance of water can then be given while the compost remains sweet. In the growing season water must be given copiously, reducing the supply on the approach of winter, then only giving sufficient to keep the leaves fresh till spring. The best time for potting or renewing the compost is when growth is commencing after a period of rest.

Raising Apples and Clematises from Seed (Idem).—If you wish to sow a bushel of Apple pips or any such large quantity, you cannot do better than sow them in beds in the open ground in spring, as if sowing Radishes, covering the pips an inch deep with free soil. That is the plan adopted by nurserymen and raisers of stocks for grafting. If you have only a few seeds any particular variety, sow them in a pot or pan of sandy soil in a cool

frame in spring. Clematis seed may be sown in the same way in a mixture of peat and loam, keeping the pots in a close and rather warm frame or light house, and the soil regularly moist.

Apricot Branches Dying (B. D.).—There is a disease to which the Moorpark is liable, and which is sometimes attended with very serious consequences. It shows itself first in the leaves, which all of a sudden flag and wither away, and the branch which bears them dies. Frequently a whole limb, or the whole of one side of a tree, will exhibit this appearance in the space of a few hours. This effect arises, not as some say from the stock on which it is worked, or the soil in which it is planted, for it is met with on every description of stock and in all kinds of soil. It is not the result of a languid circulation, for trees in the full vigour of growth are as subject to it as those which are aged and going to decay; but it is because of the naturally delicate constitution of this variety, which cannot withstand uninjured this variable climate of ours. It is caused from injuries received by frost either in spring or early summer, or in winter after a wet autumn when the wood has not been properly ripened. The frost lacerates the sap vessels of the external layers of the wood, and the circulation is limited to the inner layers. When vegetation commences, and after the leaves are fully developed on the injured branch, the demand on the powers of the branch for a supply of sap to the leaves fails, and when the sun becomes powerful and evaporation increases, the supply becomes proportionately less, and for want of nourishment the leaves flag and the branch withers and dies. Less luxuriant growth with matured wood, which can only be insured by a thin disposal of the branches, appear the chief points to be kept in mind in the cultivation of this excellent but often disappointing variety.

Names of Fruits.—The names and addresses of senders of fruit to be named must in all cases be enclosed with the specimens, whether letters referring to the fruit are sent by post or not. The names are not necessarily required for publication, initials sufficing for that. (*W. J. S.*).—The Pear is Comte de Lam. 1, Round Winter Nonesuch; 2, Golden Spire; 3, Mannington's Pearmain; 4, Ross Nonpareil; 5, Aromatic Russet. (*R. P. O.*).—Norfolk Beefing. (*Backford*).—1, Bee Pool; 2, London Pippin; 3, Small's Admirable. (*J. M. B.*).—1, White Astrachan; 2, Yellow Ingestrie; 3, Rihston Pippin; 4, Glou Morceau; 5, Beurré Rance; 6, Beurré d'Aremberg. (*F. A.*).—1, Beurré Clairgeau; 2, Easter Beurré; 3, Beurré Diel; 4, Vicar of Winkfield; 5, Golden Russet. (*J. T. S.*).—The carriage of your parcel was not paid, and it is a wonder it was taken in by our receiving clerk. If you send 6d. in stamps the fruits will be examined with the object of identification.

Names of Plants.—We only undertake to name species of plants, not varieties that have originated from seed and termed florists' flowers. Flowering specimens are necessary of flowering plants, and Fern fronds should bear spores. Specimens should arrive in a fresh state in firm boxes. Slightly damp moss or soft green leaves form the best packing, dry cotton wool the worst. Not more than six specimens can be named at once. We have received sprays of shrubs and flowers presumably for naming, but no letters accompanying them, and consequently the specimens cannot be attended to. (*N. H., Somerset*).—1, *Iris foetidissima*; 2, not in suitable condition to be determined; 3, *Carpinus betulus*. (*J. L.*).—*Solanum nigrum*. (*John Cameron*).—2, *Juniperus recurvus*. (*Lady King*).—*Ligustrum lucidum*.

WINTER DIET.

THE FLOCK.

Not until the value of green crops for ploughing in as manure is more clearly understood will the general practice

of putting sheep on the Mangold fields to consume the leaves after the roots are cleared off be discontinued. It is still practised almost universally, and is a striking example of the ignorance of science in its bearings upon practice which still exists among farmers. We have not allowed a leaf to be eaten by the sheep, but have had the whole of the leaves spread evenly over the soil and ploughed in. Let us see what is gained by doing this. Now the weight per acre of the green leaves of an ordinary crop of Mangolds is about 8 tons, and analysis shows how rich in the elements of plant-fertility is this mass of green leaves. It contains of nitrogen 51 lbs., potash 71.4 lbs., soda 65.2 lbs., lime 21.1 lbs., magnesia 27.2 lbs., phosphoric acid 15.1 lbs., chlorine 49.8 lbs., sulphur 9.1 lbs., and only 9.2 lbs. of silica. Surely it must be granted that without folding and feeding with cake and corn the sheep would leave a very poor equivalent upon the land for the consumption of the leaves? Near one of the Mangold fields where the leaves have been so ploughed in we had a field of Peas. As soon as possible after harvest this field was ploughed and sown with Turnips. Owing to the drought the Turnips grew slowly, and the heavy rain of autumn came too late for the development of any roots of a useful size; but there is a strong leaf growth mingled with Peas which sprang up from the seed falling from shattered pods during harvest, altogether forming a valuable green crop. Upon asking the bailiff what he intended to do with it, he said it would be useful for the flock after the lambing, especially for the young lambs. But, said we, the lambing will not be over till the first or second week in March, and bearing in mind that this field is to be prepared for Mangolds next year, how can we hope to have it ready for sowing by the first week in April? Moreover, all the vigorous growth of green Peas will be destroyed by the alternations of cold and wet to which it is quite certain to be exposed. Rather, much rather, let us plough in the entire mass of green growth at once, and rely upon it we shall lay up a store of precious fertility in the soil that must prove of infinite value to the root crop next season.

It is because we deplore the indiscriminate feeding off green crops by sheep at this season of the year that we have made this apparent digression from our subject. Yet it can hardly in fairness be considered a digression, for is not the feeding of sheep, in winter at any rate, generally done upon land requiring manure? Hoggets certainly are available for this purpose, and with such strong healthy young sheep we may do much by judicious folding for the improvement of poor land. For them Swedes are at once available, and we are able to calculate tolerably closely as to what the consumption must be to bring them on for the butcher, only it must not be forgotten that exposure to cold and wet may upset all our calculations. We may, however, take a mean, for to make a pound of mutton it requires 150 lbs. of Turnips out in the fields, and about 100 lbs. when the sheep have the benefit of snug enclosures and sheds. With the Swedes or Turnips a mixed diet of dry food, either of crushed cake and corn, or preferably of crushed Beans, and Oats or Barley, because the whole of this diet may be produced on the farm. Careful experiments by reliable authorities have shown that with a mixed diet the progress of sheep is much greater than when they are confined to one article of food, no matter how nutritious it may be. We must, however, see that the process of mixing and feeding is as simple as possible. Elaborate machinery and much labour are costly things in which we must not indulge, unless it is sufficiently evident that the end in view justifies the means.

It will be understood that our remarks here have special reference to wether hoggets, which are now passed on from the flock to the butcher so quickly that few of them reach the age of eighteen months. Certainly, with the present low prices we have every inducement to get them off our hands as soon as possible. With some clever farmers the high pressure system is carried so far that the wether hoggets are off

their hands by the end of July or early in August. The system has much in its favour, yet it probably answers best to select the more forward lambs for the earliest sales, and to follow with others batch after batch, so as not to incur a too heavy outlay all at once. It should be a point of good farming always to have some animals growing quickly into money, and this is managed among sheep by a process of selection, always taking a given number of the best from what may be termed the general flock, and putting them upon a more nutritious diet. In this way we avoid what is sometimes termed a "dead time," by which is meant an unprofitable time, when there is little if anything to sell, and yet payment for labour must go on.

WORK ON THE HOME FARM.

On heavy land the sowing of winter corn has been somewhat hindered. We continued, so far as was possible, to follow the ploughing closely with the seed drill. On the whole the corn has been got in well, and much of it has come up and is looking well. Of the more forward crops are Rye, Oats, Beans, and some Wheat. All are excellent plants, and the first are likely to be of much use to the sheep later on. Notwithstanding wet weather we have got through a lot of forking out of couch grass, for we still have some foul land. All of us, in some degree, are the sport of circumstances. Farms fall in, do what we will, and the land of such farms generally proves foul. No doubt in the palmy days of farming many a man hired a farm with very little knowledge of agriculture. With high prices for farm produce this did not much matter, a "living," and something more was always forthcoming, but as prices fell many a man fell too, for easy-going farming meant failure then, just as it does now. Well, we must do our best with land, be it foul or clean! To those who find the burden of hard times and labour payments press very heavily, we say, Do not forget that you have a resource in permanent pasture. On one of our off farms that is upwards of twenty miles from our residence, we shall certainly lay down a considerable area in permanent pasture next season. Meanwhile, we have striven to do all we could in clay-burning, draining, clearing the land, and judicious cropping to keep down expenses within reasonable limits. It is the expenses for labour of men and horses which mount up so seriously upon large arable farms. When the outlay passes certain limits, it is then, if not sooner, that arable land ceases to answer, and although both sheep and bullocks have fallen much in prices, yet permanent pasture may be made to answer; but mind, there must be no laying down of foul or undrained land, no trusting to the growth of natural grasses, but thorough process of culture, and the use of the very best mixture of Grasses and Clovers. Which those are we have told repeatedly, and we hope to do so again at the proper season. For now, if ever, we should have aim and purpose in our work, and our strokes should strike home, so that we may avoid failure, and do our very best still to make our farms answer.

OUR LETTER BOX.

Ploughing in Green Crops (*Auricula*).—Your query will receive more prominent attention and a fuller reply in the next issue of this Journal than can be given here.

Cabbages for Cows (*W. X.*).—Nearly all kinds of Cabbages are good for cows in full milk if they have white hearts without decayed leaves attached, but the best sort is the Drumhead Savoy, and they will not affect the taste of the milk but very slightly if without any decayed leaves. If, however, the milk is required for butter-making we cannot recommend Cabbages, but prefer Mangolds or Carrots, but best of all the large cattle Potatoes, which do not injure the flavour of the butter.

REFLECTIONS ON JUDGING.

INSTEAD of jotting down a few thoughts in a series of isolated notes, I will this week adopt a different method, and shall hope thereby to avoid criticism of a kind that provokes sharp retorts, which I have no pleasure in indulging in. In what I have written or may write there has been no intention, and will be none, of wounding the susceptibilities of anyone. It were far better not to write at all than to write with that intent.

A good deal has been said of late about judging at horticultural shows—that is, judging the products, but we do not hear so much about judging the judges; yet this is an established practice, and on the whole salutary. Reports of shows would be bald indeed and weary reading if they amounted to a mere register of the winners of prizes. Any clerk can accomplish that literary feat; but as the horticultural press attendants are something more than mere copyists they very properly endeavour to make their reports critical and suggestive. Readers of show reports desire to know something of the products that win prizes, and why they win, also to learn in what respect those which fail to secure a high position are relatively inferior. These points a practical reporter endeavours to indicate, and occasionally he may feel it his duty to question the strict accuracy of a verdict.

The fact that judges themselves are judged, not by competitors at shows alone, but by press attendants, can scarcely fail to have a beneficial influence; at least, they know quite well that if any errors are committed they are not likely to remain unrecorded. It is altogether creditable to the adjudicators at most important exhibitions that complaints are so few. The truth is, men who are really competent to estimate the merits of the products before them rarely make any flagrant mistake. No doubt some of the exhibitors, especially those who do not win such high honours as they expect, think they do; but then such individuals are necessarily prejudiced, while the judges are not, and in nineteen cases out of twenty good judges are right in their verdicts, whatever interested onlookers may say to the contrary. It is quite amusing sometimes to observe an individual throw up his arms in astonishment at a verdict, and point out how the awards ought to have been distributed. He judges the products in a minute—and the judges too—while these officials have bestowed infinite care and spent, it may be, half an hour in arriving at a fair and just verdict. The opinions of disappointed exhibitors cannot have any weight; but it is different with unprejudiced onlookers and practical men who are occasionally constrained to express an opinion adverse to the judges.

It frequently arises that judges have much difficulty in arriving at a decision, so conflicting are the claims of the products placed in competition, one quality predominating in one case and another in another. This clashing of qualities of different kinds renders it no easy matter to strike a balance

between them. In such cases the personal preferences of individuals cannot be subdued, and these may slightly vary; still, when two or three men of acknowledged competence are unanimous in giving a verdict it is prudent to hesitate in expressing an adverse opinion. At times the contest is so close that it amounts to a mere "toss up" as to where to place the cards, and equal prizes are then awarded. This is an easy method of settling the matter, and from one point of view it may be right—namely, that both are worthy of the amount that is offered, but at the same time it is questionable if two exhibits are ever staged of absolute equality.

Some such close competition appears to have existed at Bath, and it is quite evident the reporter of the Show was himself no bad judge when he had the courage to judge the judges. Whether they were right or wrong in their decision as to the relative merits of the Grapes, the admitted existence of those left room for remark, though the expressive term "favoured" may not have been happily chosen. Few, if any, however, will suppose that it was intended to suggest that anything more or less than strict justice was done according to the convictions of the adjudicators, and the word "fortunate" would have been less open to question. All the Grapes appear to have been good in some points, but Mr. Nash was the fortunate winner of the first prize. Then we come to the Pears, and we find what is to me quite a novel example of judging the judges. One evidently good judge says the finest collection, Mr. Bannister's, was passed; another judge, whose ability as a cultivator none will deny, regarded them from a different standpoint, other fruits, though smaller, yet uniform in size and quality, being regarded as more meritorious. Yet the "passed" collection is stated (page 470) on the authority of the exhibitor of it to have been granted an equal first prize. The reporter of the Show was obviously ignorant of this, and Mr. Ward makes no mention of the circumstance in his letter. Someone else, then, other than the judges granted the "first prize" in question. This proceeding cannot but be regarded as an extraordinary one; and there can be little doubt that if committees of societies judge their judges in this way some difficulty will be experienced in obtaining the services of first-rate adjudicators. The new method also practically invites disappointed exhibitors to clamour for a revision of the awards—a practice that cannot be to the permanent advantage of any society. It is open to committees to make an extra grant to any exhibitor who contributes worthily to a show, in terms outside those of the schedule, but to interfere in the awards of the judges without consulting them is an innovation that can scarcely be regarded as sound in principle, and is not calculated to increase the stability of societies nor win the approval of exhibitors.

Another matter demands attention—namely, the principle on which products should be judged. This is a subject of far-reaching public importance. When a prominent gardener advances the principle of uniformity throughout a collection as being of greater moment than individual merit, either of Pears, Chrysanthemums, or anything else, it becomes necessary to ask if such dictum is sound. If, for instance, a collection of Pears is passed because of a want of evenness in the fruits, it will become necessary to withdraw the finest dishes of Pitmaston Duchess, Beurré Diel, and other large Pears, and add smaller and inferior examples to bring them more nearly to the size of smaller varieties; and in a collection marked for its uniformity containing, amongst others, Beurré Diel and Beurré Capiaumont, it is certain the last named must be extraordinarily large, or the other correspondingly small. As an example of the weight of general evenness of moderate examples over individual merit, or each being good of its kind or variety, a stand of Chrysanthemums is introduced such as is not seen at exhibitions—namely, three large blooms and three Pompons in a collection of six varieties. It will be better perhaps to take

stands that are regularly seen and judged. Suppose, then, in a stand of six incurved blooms the back pair are as fine as they can be, and of the value of six points each; the next pair not nearly so large, but worth four points each; the remaining pair still smaller, and accorded three points each, we have a total of twenty-six points. The stand in competition is so even that the blooms examined individually are worth four points each, or a total of twenty-four points. Now the question arises, Would it be right to give the first prize to the stand that loses in intrinsic merit by two points, and the second prize to the stand which wins by that number? I leave the question open for reflection.

The same rule of judging applies to Pears. If general evenness of a collection is to stand before the individual merits of the varieties composing it, it will often be necessary to stage second-rate specimens of the larger Pears to secure a prize, whereas if the first-rate fruits excluded were placed in competition with those added, those left out would win the prize. There can be no fairer subject for criticism than this, and it is one in which nothing but good feeling and good fellowship should prevail in any discussion on the matter.—A THINKER.

REVIEW OF THE CHRYSANTHEMUM SEASON.

NOVELTIES have been brought forward in large numbers during the present season, which has been an extra busy one, as exhibitions are now more numerous than formerly; but I do not think there has been that general good quality amongst cut blooms as in some other years, except in a few instances. I fancy the severe frost of September 25th militated against the well-doing of some collections, particularly those located in low-lying districts. Those situated on more elevated sites escaped the frost somewhat more than others, while the roasting summer proved much too trying for the plants if at all neglected or where water was scarce. Those believers in well-ripened wood I fancy have had cause for rejoicing where ripened naturally, not prematurely. The season just past has been sufficient to convince me that well-ripened wood plays a very considerable part in the production of high-class blooms. For the benefit of those readers who are desirous of adding a few novelties to their stock, perhaps already too large, I will mention those varieties that came under my notice as being worthy of a place. As the Japanese are the largest in number and most generally popular I will name them first.

Belle Paule, a large full bloom with flat, long, drooping florets, white clearly margined with deep lilac. This variety was sent out last year, and this season has proved quite the best of the new ones. It is a tall vigorous grower, and with good treatment sure to produce fine blooms. This is a great acquisition.

Val d'Andorre, which is another of last year's new ones not much known, takes rank as the second best variety that has come to the front this season. It is a free robust grower, and is dwarf in habit although so strong; very fine blooms can be produced on plants 2 to 3 feet high. It is as invaluable for grouping as for cut blooms. The flowers are of large size, having a full centre with long reflexed florets, orange red shaded gold. This should be in every collection whether grown for exhibition or home decoration.

L'Adorable, a variety being sent out by Mr. N. Davis, Camberwell, is quite like the preceding variety in habit of growth and shape of flower. It is of large size, colour dark canary yellow, and is sure to come to the front next season.

L'Ebouriffée, a variety exhibited by Mr. Cannell at the National. It is of large size, shape like *Criterion*, which it resembles except in colour, which is of a bronzy gold. This, I think, will prove an acquisition.

Maiden's Blush.—This Mr. G. Stevens exhibited in splendid condition, and was rightly awarded certificates. It is somewhat after the *Elaine* type, except that the florets are longer. It is a large full flower of a pleasing shade of colour, which is blush white.

Madame de Sevin.—One of last year's new continental varieties, amaranth magenta. It is a beautiful colour, which is quite new. It is a grand variety for groups or home decoration, or when well grown will do for exhibition, but without it is in first-rate condition it is too small.

M. Astorg is a variety that has well borne out what it was said to be—a first-rate kind. I look upon it as an improved *Elaine*, as when fully expanded it is nearly white. It has long drooping florets, quite a full flower. The length of floret and the drooping graceful way they hang as compared to the short, stiff, almost erect ones of *Elaine* renders it a very desirable variety, and in that way an improved kind.

Fernand Féral, which is one of last year's continental varieties, is likely to prove a fine variety, more particularly for the early shows. It is a full flower and lasts a long time in bloom. The petals are slightly spiral, of a delicate lilac rose. It is of free growth, which is not too tall.

Beauté des Jardins, sent out last spring, is one of the best we have for decorative work. It is of dwarf habit, blooms freely, while the flowers have a strong violet scent.

Madame Laing.—A variety well shown by Messrs. J. Laing and Co. at the Crystal Palace Exhibition. Florets broad and flat, white deeply tinged with deep blush. A deep solid flower.

La Triomphante, a variety sent out by Mr. Cannell, of great promise, a very full flower, with broad reflexed florets, white.

The following I saw in Mr. N. Davis's collection at Lilford Road Nurseries, Camberwell, which I singled out as being desirable kinds:—*Jupiter*, fine large flower of a brilliant fiery red; *Mons. Freeman*, one of the broad-petalled section, rosy violet colour; *Sir Moses*, a bright crimson; *Dr. Barrie*, fluted petals of a reddish crimson, reverse of petals gold, golden centre, rather thin, but effective; *Mrs. Townsend*, rich in colour, which is a claret crimson, very fine; *Galatea*, a large flower, blush rose in colour.

New incurved varieties are very few in number; the only new one that promises to be a valuable addition is the bronze sport from *Queen of England* shown in several places by Messrs. J. Carter and Co., High Holborn, London. If it remains steadfast in colour and form as shown by them it must become a valuable addition to the incurved section, as it is so distinct in colour to any of the large varieties now in commerce. No doubt Messrs. Carter will grow and prove it more fully another year, when it will probably have a large demand.

Lord Alcester has gained in popularity since its introduction immensely. I rather think it now beats *Jeanne d'Arc*. Such a good "doer" is it that it may be seen in almost every collection. One thing I am sorry to see some of the raisers are doing—pushing worthless varieties into the market and calling them incurved, whereas they are nothing but mongrels, neither Japanese nor incurved. I think the object of the raiser is a good one—that of getting the bright colours of the Japanese section infused in the incurved; the consequence is the progeny is neither one thing nor the other in form, which is or should be the one great object in all incurved flowers.

Reflexed varieties have received a most valuable addition in the variety *Cullingfordi*. I consider this quite the best of the whole family either new or old; its colour is so striking, the flowers are of such depth and substance too, and with such lasting properties. This variety is sure to become popular. At one time I was in doubts whether it would be admissible as a reflexed variety, but now I consider that is its proper place. I know it is a hard matter to define which are Japanese and reflexed varieties. Some say there ought to be a class for reflexed Japanese. That, I think, would be more bewildering than ever, because the generality of the florets of the Japanese varieties reflex. Take, for instance, *Fair Maid of Guernsey* and *Belle Paule*, both decided flowers of that habit; therefore it would be almost impossible to define Japanese reflexed. The true type of a reflexed flower, or what might more properly be termed imbricated flowers, is *Golden Christine*, *Emperor of China*, *Cloth of Gold*, or *Dr. Sharpe*, for this reason—the petals of those varieties do imbricate, and they are much shorter in the centre of the flower than the outer ones. This is not the case in some of the Japanese varieties, which some say are or ought to be shown in the reflexed section. Take, for instance, *Triomphe du Nord*, and this is spoken of more than any other variety that ought to be admissible. In the reflexed classes the petals of that variety are much nearer of the same length than the petals of the varieties I name as being the correct reflexed type. A true reflexed type should be full—scarcely any space between the points of the petals. Now in some Japanese varieties there are very wide spaces between the tips of the petals, nor is the imbrication perfect through the petals being of the same length as each other. I contend that *Cullingfordi* has these requirements. I am prepared to find many people differ from me as to the constitution of the various sections of the *Chrysanthemum*, but in this particular instance I am unable to define it more clearly.

Through the kindness of Messrs. J. Laing & Co. I was enabled this season to grow a plant of the true *Mdlle. Madeleine Tezier*, as suggested by the *Journal*, the variety that was supposed to be synonymous with *Jeanne d'Arc*. Flowers produced by this plant are decidedly reflexed, white, delicately tinted with blush, heavier round the bottom petals. It is of large size and full centre—quite an acquisition to the reflexed class. Distinction is another valuable addition to this class, under which heading it was sent to me last spring. Some catalogues describe it as a Japanese variety. The colour of our variety answers to the description given in the

catalogue under the Japanese heading. It is one of the deepest built flowers I know, close in the petal, and very solid, while the colour is yellow, shaded and speckled with reddish crimson.

Mdlle. Melanie Fabre, soft rose flamed with a darker shade, I saw in Mr. Davis' collection. When better known I fancy this will prove to be a good reflexed variety.

Marguerite Villageoise is the only good new kind produced this season among the Anemone Japanese section. This is one of Messrs. J. Laing's introducing. It is extra large and full in the centre, having what is termed plenty of "stuff" in it. As it is so distinct from any other variety it will be a useful addition. It is a deep lilac, tipped with a much lighter shade. If Messrs. T. Jackson & Son, Kingston-on-Thames, can bring out perfectly the White Fabian they have in hand they will do good service in this family, which is very interesting.

Bacchus is a variety exhibited this season as Anemone Japanese, and a good one it would be if it had a better centre. Its colour is very rich claret colour. Perhaps it was not in good form when staged; if so it may improve by culture. I noticed nothing new among the ordinary type of large-flowered Anemones, nor did I amongst the Anemone Pompons. The latter is a very interesting class, either grown for single flowers or in bunches, in which style they are very useful and effective in a cut state. Among the Pompons we have a very fine addition in Black Douglas, sent out by Mr. Cannell. As its name implies it is the darkest of the whole family, particularly full flower, good round form, and, as the petals are thin, it is devoid of all coarseness sometimes existing in some varieties of Pompons.

It is very pleasing to notice the general improvement throughout the country of the groups composed wholly of Chrysanthemums now that the system is becoming more studied and put into effect—a system taught and explained and forcibly illustrated by the groups arranged at several of the Kingston Shows by Mr. C. Orchard, The Gardens, Coombe Warren; but I venture to say that the best group yet staged was one this year at the same Exhibition by Mr. J. Buss, gardener to A. S. Price, Esq., Parkside House, Ewell; so dwarf were the plants, such healthy foliage and excellent blooms, and above all the arrangement of the colours was charming, so happily were they distributed.

Specimen plants are much better trained now than they were. A few years since the object was to get them as flat and as large as possible; now they are not nearly so stiffly tied. The quality of the flowers, too, is studied more than mere quantity. At exhibitions which have not long been in existence there is a great want of skill in the specimens, simply because no opportunities have been to see which is the best way to grow them. After a year or two a vast difference is discernible—the old-fashioned plants 5 feet high, a forest of stakes and leafless stems tied together reminding one of as many birch brooms, and the flowers so produced scarcely showing the true character of each variety; many that ought to be full-centred have large yellow eyes resembling single varieties more than anything else. These quickly make room for those dwarfed-grown plants, which can be seen somewhat more comfortably without the aid of step ladders, each plant representing the true character of each variety. This new state of things requires a little time and some study and careful handling, but when achieved the results are much more satisfactory both to the general observer and to the cultivator.—E. MOLYNEUX.

FRUIT AND PLANT HOUSES.

(Continued from page 445.)

STRUCTURES with flat eave plates allow the water passing down the rafter to lodge, and this is sucked up by the rafters, especially when the joints are not tight, which causes speedy decay; indeed, I have seen the rafter decayed at the under side for a yard or more up, whilst the external surfaces were comparatively sound, and this within seven years after erection. The woodwork ought to be so contrived that water will not lodge upon it either outside or inside the house. This is effected by chamfering off the right angles of the wood, and in a pleasing manner by the skilful horticultural builder. The sloping of the woodwork is also commendable through allowing a freer access of light to the interior, and it to some extent is useful as a preventive of drip so inimical in fruit and plant houses; indeed, they ought to be drip-proof, to effect which desirable result various expedients have been employed, such as strips of zinc on the under side of the rafters with the edge turned up so as to form a gutter on each side and convey the water to the bottom of the rafters. This is only a cobbling business and objectionable from obstructing light. Messrs. Foster & Pearson, Beeston, Notts, have the rafters or sash-bars with a groove on each side near the lower edge, which entirely prevents drip; at least, I failed to find a single drop of drip in a house constructed by them 54 feet long by 15 feet wide during the

dripping murky weather of this November. There is nothing so unpleasant as the drip, or rather miniature shower bath greeting those entering a house where moisture condenses and lodges over the doorway, and which is overcome by a very simple contrivance of a strip of metal inserted in the lintel, which prevents the water lodging over the door.

These are, it may seem, trifling matters, but they, notwithstanding, form the very foundation of the structure as regards economic and cultural value.

Before quitting the woodwork I ought, I think, to mention a letter I received from a firm of horticultural builders taking exception to my recommending pitch pine, as they find it subject to "dry rot," which I have to some extent noticed when this wood has been used in stables, but I have not noticed it when creosoted and used for houses that were kept at a uniform heat and moisture as that of moist plant houses. Nevertheless, I readily grant there is no objection to be taken to sound well-seasoned red deal. At the same time I would prefer teak for all structures, especially where the temperature is high and the atmosphere moist, but it is considerably dearer, though cheap in comparison with the materials used in many structures. There is as much difference in the appearance and wear of a house constructed of the best material in a proper manner compared with the showy and cheap (?) as there is in the textile fabrics between wool at first hand in broad cloths, as compared with the taking prices of shoddy. I am thankful for the above opinion, and only wish those holding different views would favour us in these columns with their observations and experiences.

The next most important matter is glass. I have used polished plate such as is silvered for mirrors, of various thicknesses, also the same ground on one side, rough or rolled plate, and glass of varied tint, without any remarkable discovery. The only ray that I have found of any benefit is that of the sun passing through glass slightly tinted green; the glass found in all our very old houses in tiny panes, as thin as a hard-worn sixpence, and known as crown. This has gone out of date, as it was too fragile and too uneven in thickness. For its thickness it was the toughest of all glass from the care exercised in annealing. This has given place to sheet glass—the best unquestionably if only it be good, and the only good is English, the foreign being unreliable both in quality and thickness. I prefer it with a green tint scarcely perceptible to the eye, nevertheless apparent in all our best English makes. Without prejudice to other manufacturers I may mention that of the Hartley's, Sunderland, as what horticultural glass should be. Fifteen or sixteen-ounce sheet of the quality known as thirds serves for ordinary purposes, but in the size of panes now employed it certainly ought not to be less for the roof than 21-oz., whilst for the sides and ends the lighter description answers. Twenty-six ounce, and even 32-oz., I have used without any advantage over the 21-oz., and as for plate it is only going to a great expense for no object only to parade extravagance. Thrift is wanted without abatement of utility. I have not seen any beneficial result accrue through the employment of plate glass or even of thick glass, provided that used is of sufficient strength to resist ordinary storms of wind, rain, snow, and hail.

Thick glass is supposed to prevent the radiation of heat more than thin; but I never found any sensible difference in houses glazed with plate from a quarter to three-eighths of an inch thick to what were the results in those glazed with 21-oz. glass. It made no difference in the heating surface required, consequently none in the fuel consumed; besides, I consider the solar rays pass more entire through thin glass than through thick. The rays being deflected in passing through the glass the diffusion must be greater in passing through thick than thin, and the rays are effective or defective in proportion to their directness. Rough plate is an example of this; the rays, though they may not be less, are more diffused—the same light, but broken, and less effective on plants in respect of evaporation, elaboration, and solidification—the essentials of fruitfulness. I readily grant plants will grow quicker under a roof of rough plate, attaining more ample foliage; still, it is not desirable glass for general purposes, and where a maximum of fertility in flowers or fruit or both is desired it is absolutely unsuitable. It may and does answer for foliage plants such as Ferns and Palms, but for those even that require light for the perfect colouring of the foliage such as Crotons, &c., it is positively inimical; indeed, it is questionable if the glass for all purposes ought not to be smooth and clean, depending upon temporary shade for protection against scorching rays, which, by the way, I may state are more due to inattention to early ventilation than any defects of glass. Even rough plate should have a green tint, as white, or, worse still, yellow, takes the colour out of Ferns and Palms, giving them a sickly yellow hue instead of that deep pleasing green so desirable.

As to glazing I do not propose to trouble your readers with the many different modes. I have no fancy for the tempting bait novelty or change, as I find nothing better than the old-fashioned putty

glazing, without any of it above the glass. Provided the glass is properly bedded in putty, it is taken off level with the upper surface of the glass, and the squares are securely nailed in, there is no objection to be taken to it. There is no leakage if the work is performed in a proper manner and the painting duly attended to. It is simple and effective, the glass readily placed in position, and repairs can be expeditiously effected by any person of ordinary intelligence. I am a staunch believer in laps, jump joints are useless, but the smaller the lap the better, and in no case should exceed a quarter of an inch—an eighth is still better, yet there must be a perfect lap from one side to the other, and not half an inch on one side and barely an eighth or none at the other. A large lap means water lodging and much repairs to do after the first severe weather, with, in the course of time, a strip of opaque matter across every pane corresponding to the width of the laps, and extending from neglect in washing over a great portion of the surface. Some people have an idea that wide laps are useful for ventilation, which they surely do not believe, or they would be more particular in keeping them free of accumulations of dirt. They are useless in that way, and serve no purpose only to make a frequent acquaintance with the glazier, to say nothing of their obstructing light, which every cultivator needs so much in winter.

There is one other matter in connection with glass in respect of the formation of the squares which deserves more than passing comment. When the squares or panes are cut square the water for the most part follows the rafter or sash bar, but the lower part of the square being convex, the upper part of the square of course being cut concave, the water is directed to the centre of the panes and runs down the centre of them to the gutter. Water does not lodge in the lap, as it drains to the centre, and passes away without leaving a drop, so that the danger of breakage from frost is reduced to a minimum, and the water is taken away from the parts most liable to decay or the rafters.

As regards paint it is needless to point to its necessity, but it is no use deferring it until the woodwork is in position, for should rain fall the pores and the joints will have absorbed all they can, and the painting is only so much material and labour wasted. The woodwork ought to be painted with at least two coats before fixing, and every joint or wherever a joiners' tool is employed on the woodwork in erecting it should be well coated with paint so as to cover it well and render the woodwork proof against the absorption of water. After fixing it should have two coats more, and due attention be afterwards given to its renewal, which is the better of a coat every year, but certainly should be given every other year, and then two coats. Of paints I have a preference for white lead brought to the proper consistence with linseed oil, with the needful turpentine for drying, but for wear a light stone colour is certainly preferable, as it does not show dirt so soon as white. Whatever the paint it should be the best lead and oil colour, and the less of the light substances as brown umber, or blue, &c., the better. The ironwork ought also to be painted before fixing, and if finished off a light blue the effect is pleasing. Black is too violently contrasting, and is the poorest to use imaginable, though very commonly employed. The dull red or chocolate now so fashionable is very durable, but unsightly.—G. ABBEY.

(To be continued.)

FORCING LILY OF THE VALLEY.

THE rapidly increasing popularity of these charming flowers is fully illustrated by the hundreds of thousands which annually reach this country from various Dutch, German, and other growers, the demand for clumps being on the decrease, and that for single crowns rapidly increasing. This preference for single crowns seems to arise from various causes, primarily, perhaps, from the fact that they may be obtained much more cheaply, and cost far less for carriage. A thousand single crowns, for instance, will go into a comparatively small box, the cost for carriage being trifling, while the clumps containing the same number of flowering crowns would constitute a rather bulky load. Single crowns, again, are more easily dealt with than are clumps, and may when being forced be placed into a very small space, while clumps must be potted—the smaller ones into 48's and the larger ones in 32's.

Having just received my first batch of a thousand crowns in boxes, it may be serviceable to some at this season of the year when so many are anxious to do them well if I state briefly the mode of procedure. This is so very simple that it is within the reach of all who possess a stove, and where a uniform bottom heat of from 75° to 85° is maintained. To be clearly understood in this matter I will ask the reader in thought to accompany me back a few weeks to the time when these crowns are first received either from the Continent direct or from his own seedsman at home. To get them early is always an important point. This I urge as important, so

that the crowns shall not be exposed to the vicissitudes of our ever-changing climate any longer than is possible. As soon as received they should be laid in the soil in the bundles as received, taking care to cover them with at least 4 or 6 inches of soil, and not leave the entire crown exposed as is often the case. I find coal ashes excellent to bury them in, and being light and open the frost does not penetrate deeply, and the crowns may be got at any time. I strongly recommend their being thus buried as soon as received, for this reason that they force better, and are not so liable to rot off at the neck of the crown as when left exposed to external influences. This is more noticeable in the earliest batch, and which need hard forcing. When they have been exposed, and are lifted and placed in heat at once, I have noticed a blue fungus form around the base of the crown, which eats them off in about a couple of days. This fungus is a rarity if the crowns are deeply covered, and which seems to keep them plump and fresh and ready for action; certainly it is a more natural state for them.

In some nurseries Lilies of the Valley are forced in great numbers, and special accommodation is at hand. In such cases they are generally planted out in the houses on a bed with plenty of bottom heat. Where smaller quantities are required the following will be found to answer well. I obtain some boxes 3 feet long or thereabouts, and about 22 inches wide and 8 inches deep. Such an one will take about four hundred crowns. Previous to untying the bundles I shorten the roots to about 4 inches long, after which they are placed in rows in the boxes as thickly as possible in cocoa fibre refuse, there being about an inch between the rows, and a similar distance from crown to crown, when the box is filled with as many as can be packed in it. Fill the box level with fibre and press rather firm, when they may be removed to a frame or pit slightly heated. Having been in this temperature a week or so they may be taken to the forcing house and placed on the bottom heat, and by covering them with slates a greater amount of heat will be retained than otherwise, and which also serves to keep them in darkness.

Given a constant bottom heat as above stated, they may be had in flower in about three weeks or a month, so that there is just time to get a batch in for Christmas, at which time they will be most acceptable. After that time, and especially if they have been brought on gradually, they come on much more quickly, and after the first early batch, together with giving a greater per-centage of flowers, we get foliage too, which is generally minus in the earliest batch. To meet this we lift some old patches from the ground and place them in strong heat under the stages perhaps, where they get sufficient light to give them colour.

While being forced water should be plentifully supplied, and at about the temperature of 75°. In about a fortnight they will be pushing through, when the slates must be removed. A hot-water circulating tank, having a direct feed from the boiler, constitutes my bottom-heat bed, which at the hottest end often exceeds 90°, and sometimes reaches 95°. At this point, however, I place the boxes on pots, allowing a 3-inch cavity. Here they come on admirably, and are all that could be desired, and after all they are not so difficult as many imagine, and being in boxes are easily transferred to a cooler house to harden off.—J. H. E.

NOTES BY THE WAY.

KEEPING POTATOES.—It may not be generally known that Potatoes can be kept sound and well-flavoured until next year's crop comes in. The following is the method (said to be a French one), which I closely followed with the best results:—A large boiler of water, the water being kept up to the boiling point. The Potatoes when well washed (avoid breaking the skin if possible) are placed in small baskets or nets, which are then rapidly thrust under water and there retained for about four seconds. The tubers in each batch on being withdrawn are spread out on the flooring to dry; when dry they are stored away in a dry dark room as nearly air-tight as possible. The Potatoes by this process will have lost all tendency to germination.

CALLA ÆTHIOPICA AS AN AQUATIC.—Several large pots of the above were sunk in the lake here over two years ago. In winter they are quite 3 feet below water level; though frozen last winter, yet they did not fail to throw up two or three good spathe to each pot in spring.

JUDGING CHRYSANTHEMUMS.—While willing to acknowledge Mr. Murphy's ability as a scribe, yet I do not think that he has any cause to be "sorry" that Mr. Pithers wrote so plainly of the Dublin shows. In my opinion Mr. Murphy's glossing over mistakes will be more detrimental to the cause he has at heart than Mr. Pithers' plain speech. "He that heareth reproof getteth understanding."—C. S. RITCHIE.

TRAINING PEACH TREES.

WITH reference to my remarks on this subject (page 407), Mr. Simpson, Wortley Hall, Sheffield, informs me that he advocates the two-limb system with maidens "for the sake of clearness to beginners," and that personally he is not particular, but "fills the house with bearing

wood as soon as he can according to circumstances." How rapidly this is accomplished may be gathered from some of the facts mentioned in his book on "Improved Pruning and Training Fruit Trees." For instance, a small and comparatively weakly Victoria Nectarine, a rider "with a few shoots upon it, and a stem as slender as a young Briar stock," was planted early in 1878, and the next season perfected a crop of five dozen good fruits, while during the season of 1880 this and other young trees planted at the same time bore from nine to thirteen dozen fine fruits each. Mention is also made of extraordinary and most rapidly grown trees of Peaches and Nectarines at Brayton Hall, Lambton Castle, and Eastnor Castle, and some time ago the Peach houses at Wilton were also described in this Journal, these fine houses being very rapidly filled on the unrestricted system. Plenty of other instances, including Cardiff Castle, could be quoted, were it necessary, in support of this decidedly improved system of training.—W. IGGULDEN.

[We have seen the Peach and Nectarine trees at Wortley Hall, and they were very fine indeed.]

WHITE PLUME CELERY.

I AM pleased in having the opportunity of giving Mr. McIndoe (page 443) some information on this. Snow will do it no harm, and only a severe frost which will injure other Celery will destroy it. Last winter it showed no signs of being injured after 12° of frost with us, but I dare say a severe frost would blacken it and make it pulpy. However, Celery is wanted before as well as after frost, and for use from the beginning of September until Christmas at least no Celery could surpass this in good qualities, especially for cooking as a second-course vegetable. "Utilitarian" (page 465) makes a mistake respecting this Celery. Evidently he never had it to try, as it is not at all like Cole's Superb Crystal White. Every portion of our plants becomes creamy white, and there are no green ones, but all are alike pale. As Mr. McIndoe seems to look at it from a reasonable point of view and comes to no hasty conclusions I shall have much pleasure in posting him a pinch of seed of the right sort in February next.—A KITCHEN GARDENER.

THIS White Plume, like all other plumage, looks best in fine weather, for 10° of frost ruined it. On examining the White Plume Celery after a night's frost, which we experienced here lately, we found that not much "white" remained, "decayed brown" I should think would describe its appearance; so that Mr. McIndoe need not wait to see how it would survive a snowstorm, for it is quite evident that it will not survive much frost.—R. GILCHRIST.

CERTIFICATED CHRYSANTHEMUMS.

AS noted in another page, at the meeting of the National Chrysanthemum Society, Wednesday, the 25th ult., the Japanese variety Belle Paule, which has already been described, was shown by Mr. N. Davis and Mr. Forbes, both receiving a certificate for it. Another variety from Messrs. Cannell & Sons was also similarly honoured, and appears likely to become fine for exhibition. This is described below, also Cullingfordi and Pietro Diaz, which were omitted last week.

BEAUTY OF SWANLEY (H. Cannell & Sons).—A handsome large semi-globular bloom of the Japanese type, with broad flat or slightly fluted erect and spreading florets, very full and of a soft rosy lilac tint. Very pretty and distinct as shown.

PIETRO DIAZ (M. Sullivan, Downshire House, Roehampton).—A large Japanese variety, with somewhat reflexed florets bright red, the margin and under surface golden. The plant is of dwarf habit and free-flowering. Certificated by the National Chrysanthemum Society.

CULLINGFORDI (C. Orchard).—This was certificated last year, but a similar honour was awarded at Kingston to Mr. C. Orchard, who grows it remarkably well. It is a grand variety, in colour an intensely rich crimson maroon, quite unequalled in that respect; the florets are also broad and reflexed in young blooms. Some dispute has arisen respecting the class in which this should be admitted, and unfortunately the confusion has been increased by the Kingston Society deciding it to be a Japanese, and the National Society, on the other hand, determine it to be a reflexed. As usually shown it is much better in the latter class.

Mr. W. E. Boyce, Holloway, writes: "In looking through your interesting account of Chrysanthemums certificated in 1885, I observe that you state Mr. Davis was awarded a first-class certificate for CHRYSANTHEMUM POMPONUM. The fact is, both myself and Mr. Davis exhibited Mandarin and Pomponium the same day. Mr. Davis was awarded a certificate for Mandarin and to me for Pomponium."

Several correspondents desire the address of M. B. Ghys, mentioned last week as the author of the "Essai sur le Chrysanthème." It is thus given on the work in question: "M. B. Ghys, Pharmacien, à Anzin (Nord), France." The "Essai" contains thirty pages and is published at the price of 1 franc.—L. C.

JUDGES AND THEIR WORK.

I WAS rather amused when I read the letter of Mr. L. V. Heathcote, to find how well the cap fitted at Leicester. I will not promise to satisfy his curiosity further than to say that I expected a reply from an entirely different quarter, and I shall be satisfied if the cap does not fit another midland town equally as well as Leicester, but perhaps they have profited by past experience and select judges from old exhibitors, or someone equally competent.

I am very pleased Mr. Heathcote has three such men who are thoroughly practical and experienced gardeners, as I have found but few such in our district who understand Apples and Pears, Potatoes and vegetables, to say nothing of the choicer kinds of fruits, flowers, and plants.

But there is one sentence I can hardly understand—"The remarks of 'J. L. B.' are absolutely untrue, and even if correct are a direct insult to the gentlemen referred to"—so I will leave it for others to solve. I may add that I had no intention of insulting anyone. A disappointed exhibitor is a very favourite term just now to apply to anyone who dares to say anything against judges.—J. L. B.

APPLE LADY SUDELEY.

THIS very beautiful early and highly perfumed Apple was first shown as Jacob's Strawberry at one of the meetings of the Royal Horticultural Society last year, and attracted a great deal of attention. It was grown and exhibited by Mr. Jacob of Petersfield, who cannot give any very definite account as to its origin; but whether it is novelty or an old variety rediscovered, it was unknown to all the most experienced fruit-growers who attended the meeting. The fruit is above medium size, being rather inclined to be large, over 3 inches in

Fig. 74.—Apple Lady Sudeley.

diameter, and exceeding 2½ inches high. It is roundish and bluntly ribbed, the ribs extending to the crown, where they form rather prominent knobs or ridges. The skin is bright golden yellow, almost entirely covered with brilliant dark crimson stripes shaded with paler crimson. On the shaded side the colour, with the exception of the ground, is paler; the surface is thinly strewn with fawn-coloured dots. Eye closed, with spreading connivent segments set in a deep and ribbed basin; tube conical, inclining to funnel-shape; stamens marginal. Stalk short and stout, deeply inserted in a round cavity. Flesh yellow, tender, very juicy, sweet, agreeably subacid, and of a highly perfumed flavour. Cells abaxile, obovate.

It is an early Apple of great beauty and excellence, ripening in August, and continuing in use till October. It has been well shown this year by Messrs. Bunyard & Co., Maidstone, by whom the stock has been acquired.

FORCING PLANTS.

IN gardens where large quantities of flowers are required it is necessary to set a house apart entirely for this purpose, which should be made perfectly sweet and clean without further delay. If the house selected contains a bed which can be filled with fermenting material so much the better, for flowering plants advance more rapidly by the moist genial heat derived from such a source than when the necessary temperature is maintained by hot-water pipes. Leaves are now plentiful in many establishments, and if good quantities have been stored away in a dry state for this purpose the fermenting material will not give much trouble in preparation. Oak and Beech leaves are the best for this purpose, as they contain heat for a much longer period than is the case

with those from other trees. One-third of long litter from the stables should be mixed with the leaves; but this should be well shaken out and thoroughly mixed with them, and the whole thrown into a heap in an open shed. If allowed to remain in this condition for two or three days fermentation will have commenced, when the whole should be turned daily to throw out rank steam. It is necessary to be careful in the preparation of this material before placing it in the house, for if not properly prepared before the bed is made up the ammonia thrown off will discolour the paint of the house, and will give a strong violent heat for a short time only; in fact, the material quickly decomposes if the bed when made up contains an excess of moisture. The time required for preparation will depend entirely upon the condition of the material as to moisture when the leaves and litter are first thrown into a heap. If well and judiciously prepared, and too much litter is not used, the bed inside the house will throw off a gentle moist heat, and continue to do so for a long time. This is what is needed, and the heat directly it displays any tendency to decline can soon be restored again by the introduction of a few barrowfuls of fresh material intermixed as the bed is turned over. When due care has been taken in the preparation of the material a few days only need elapse before the house can be filled with plants.

At first such plants as Ghent, Mollis and Indian Azaleas, Lilacs, Deutzias, Spiræas, Lily of the Valley, Tea Roses, Tulips, Hyacinths, and many other plants that it is necessary to bring forward, may be stood on the surface of the material for a few days or a week, and afterwards plunged. The varieties of Azalea indica are best stood upon the surface and not plunged. The bed of fermenting material will at first supply plenty of heat without the aid of that derived from the hot-water pipes. Nothing is gained by starting these plants in a high temperature, for they may fail to move if a hard uphill system of forcing is adopted. If the plants have been previously prepared for early forcing, all that is needed is a close atmosphere and a little warmth to excite them into activity, and when once growing a higher temperature may be maintained until they commence to unfold their flower buds. Directly they reach this stage they should receive cooler and more airy treatment, so that the flowers when expanded will contain colour and substance. Tea Roses should not be subjected to a higher temperature than 55° at night, neither should the temperature of the forcing house exceed 60° after the plants are once started. An exception of this may be made in the case of Lilac, Lily of the Valley, and Spiræas, for they will bear strong heat without injury.

Roses.—To succeed the Tea varieties introduced into the forcing house the next batch of plants should be under cover where they can be preserved from frost ready for introducing at any time, according to circumstances and the demand for flowers. The Hybrid Perpetuals intended for the earliest batch, and still outside, may now be pruned back and placed in a cool house. If required in bloom as early as possible, place the first batch in a vinery or Peach house ready for starting where the trees are intended to produce an early crop of fruit. The batch to follow them may have the protection of a cold house. The remainder of these varieties can remain outside for some time longer if the pots are plunged. All Tea varieties not yet wanted for forcing should be placed in cold frames or cool houses, where they can be protected from frost.—W. B.

JUDGING PEARS AND GRAPES AT THE BATH SHOW.

I THINK Mr. Ward has not improved his position by the use of the argument adopted on page 465. Not only did I express an honest opinion, but it was also the opinion of many practical gardeners, all known to both Mr. Ward and myself, and whose names I could give, that errors of judgment occurred more especially in the Pear classes. Mr. Ward claims to have been consistent throughout the classes, but it has yet to be proved that consistency and correctness of judgment are necessarily conjunctive. In my opinion, Mr. Taylor's Alicantes were very superior to any staged as far as finish and denseness of bloom were concerned, and should have been either first or third. They were not so "gappy" as Mr. Ward represents, neither were the third-prize bunches so "dirty" as he states they were. Mr. Nash, for whom I have great respect, is one of the most uniformly successful exhibitors at both the Bath and Bristol Shows, no one ever I should say grudging him his success, and his Alicantes are usually superb. This season he exhibited perfect bunches in August, but those shown at Bath were cut from overcropped Vines and were not so black as they might have been. When I used the word "favoured" I did not imply unfairness in decision, but, with the Editor's permission I will withdraw it and substitute lucky.

Mr. Ward did not, I think, attend the Bristol Show, yet he asserts that Messrs. Nash and Taylor "occupied the same positions with the same Grapes there." How does he know they were the same Grapes? and even if they were, two bunches only instead of three as at Bath were shown, and this might easily have made a material difference.

As to the Pears, I think it would have been better if Mr. Ward had let my criticism pass unnoticed. His estimate of Mr. Bannister's six dishes of four fruits each, not six, was wide of the mark, as there was no such marked disparity as he asserts. What if Pitmaston Duchess were in one dish, and that very small sort Winter Nelis in another? or, to adopt Mr. Ward's argument, what if three large-flowering Chrysanthemums were on the same board as three Pompons? If the latter were to be included, and were as well grown as their bigger brethren, must the fact of their being naturally small necessitate their being "passed?" My contention at the Bath Show was that each variety ought to have been judged on its own merits and without reference to its neighbours, and I

repeat it here. Every dish Mr. Bannister staged was equally good. Ripeness had nothing to do with it, ripe fruit only being stipulated for in the case of a single dish of Pears. In the "Notes and Gleanings" of last week it will have been observed that the Bath Committee awarded Mr. Bannister an equal first prize. What Messrs. Coleman and Wildsmith would have done at Bath nobody knows, and their names might well have been left out.—YOUR REPORTER.

VENUS'S EARLY DWARF CABBAGE.

If Mr. Venus has any Cabbages ready at the time when Mr. Inglis sends his collection to the Fruit Committee for their inspection he has no objection whatever to sending them, but as Howick is much earlier than Allerburn House, it is possible they may not be ready at the same time. However, I enclose some seed of Venus's selection, and if Mr. Inglis will send some of his perhaps the Editor will be kind enough to have them grown side by side, and under the same circumstances, and report thereon. This, I think, will be a fair way to decide the matter.

Mr. Inglis understands that Venus's Cabbage is a selection from Cook's Early Dwarf, and that he is in possession of a selection from the same variety, which he believes is superior to that possessed by Mr. Venus. This is certainly an admission that Mr. Inglis thinks there is a difference in the two selections.

It is nearly twenty years since a few Cabbage plants were selected from a seed bed and given to Mr. Venus. During all that time he has always selected the largest and finest for seed purposes. So long has this Cabbage been connected with the name of Venus, and so familiar in this neighbourhood that, when recommending it, it never occurred to my mind to make any inquiry as to any original name that it might possess.

I have only once seen Cook's Early Dwarf growing. What I saw were more globular in form, and not near so large as what we have had from Mr. Venus. My only object in recommending this Cabbage was simply to try and make more widely known a variety that I knew was of great merit, and I thought too little known.

During the past twenty-six years I have derived much pleasure and profit from the *Journal of Horticulture*, and thought I might be doing some good in recommending such an excellent article.—JOSEPH OLIVER, *Eslington Park, Alnwick.*

[We will have the Cabbages fairly tried if Mr. Inglis sends us seed as suggested.]

ALPINE PLANTS AND THEIR CULTIVATION.

THERE has long been a general though erroneous idea that the culture of alpine plants is beset with great difficulty; this, though lessened during the past few years, is by no means fully dispelled, for many would gladly take Alpines in hand, but they have no rockery, and appear to think that such a structure must be of great height. That such ideas are without foundation is obvious if we consider for a moment the great altitude at which many of the choicest plants of Alpine regions are found. Is it not rather a matter for surprise that we can successfully grow such numbers of them at home in the lowlands? Such great altitudes are not indispensable in the culture of these plants, nor do we require elaborate and expensive rockeries; indeed, a number of them may be successfully grown in good soil on an even surface.

One of the primary points in the cultivation of alpine plants, and indeed any other class of plants, is a fondness for that particular group of plants. Nothing which may be written can in any degree compare with the picture presented by the Alpine region in flower, and nothing can in any way enlighten those who indulge in their cultivation so much as to see them growing in their native haunts. There is many a hint, many a small secret, to be gained as to their preference to this or that rock against which it may be growing. Happily, however, this preference of soils is confined to few species under cultivation, since plants which are said to have a distinct hatred for such and such soil have been grown luxuriantly in that particular soil, so that it would appear that such precise preparations are not indispensable. This has repeatedly been the case during my own experience, and I may here mention two plants, *Rhododendron ferrugineum* and *hirsutum*; the former in a wild state always (or nearly so) inhabiting granitic rocks, and the latter limestone; and not only do travellers recognise the two species by their habitats (for the flowers are very similar), but they even assert that neither will grow on the opposite formation. Whether this be so or not I cannot determine, but neither limestone or granite is indispensable in the cultivation of the two species, both having grown in company with *Daphne cneorum* and *Andromeda* in a mixture of peat, loam, and sandy grit. For another instance I would name *Gentiana verna*, one of the loveliest plants of the Alps, often found at high elevations and reputedly fond of limestone; the same plant, however, occurs, though less frequently, in England and Ireland, and when found within the limits of our own isle it is invariably in a rich loamy pasture. Seeing that it does admirably in loamy soils generally under cultivation, the limestone

portion need no longer be regarded as essential to its well-being or success.

Other instances I have in mind where *Saxifraga Burseriana*, *Gentiana pumila*, and *Edraianthus dalmaticus* grow to the greatest perfection in loamy soils of ordinary character, by which I mean not specially prepared soil, and which receives annually a dressing of manure. Here we have three choice alpenes growing luxuriantly in ordinary soil containing manure. There are few growers of alpenes which allow them manure, but I am assured that they benefit by it. My reasons for dwelling more particularly on the food of choice alpenes, and in doing so to show how indifferent are many of the so-called alpenes to the soil in which they are placed, is to endeavour to remove the opinion that particular soils must be had for certain plants. Laying down hard-and-fast rules as regards soil has debarred not a few from enjoying these modest beauties of the Alps in our gardens at home, and kept many more from attempting their cultivation. The majority of alpine plants may be grown with complete success in a fairly rich sandy loam; others prefer peat, and others peat and loam in equal proportions. Those that will not thrive in such soils as these are few, and their failure may readily be traced to other causes. Where limestone is deemed essential to a few plants, and not easily obtained, it will be best supplied in the shape of old mortar rubbish. For such plants as the encrusted species of *Saxifragas* this is agreeable to the plants, though by no means essential to their success. Lime, too, is very often supplied without thought; for example, some waters abound in lime, and when the plants receive copious supplies those which are supposed to delight in it and those that abhor it all receive it alike.

One thing which the alpine tourist would always do well to note is whether any particular plant or plants prefer wet spongy ground to dry rocky soils, and whether they generally grow in sunny or shady spots. No doubt they will be found to occur in a variety of situations and soils, in which case the most luxuriant plants should be examined and noted accordingly. It may not be generally known that in a wild state *Helleborus niger* to a considerable extent inhabits soils abounding with granitic rock, out to insure success in England we give it a deep and thoroughly enriched loam, and these cannot be either too deep or too good for these plants. *Pinguiculas* in their mountain home are not unfrequently found on banks of steep stones, not singly, but by thousands, the stones being kept moist by trickling streams from above. Here it would appear that the one great want is supplied by the moisture alone, and without which the plants would soon perish. I have seen this mode of growing them well illustrated in the York nurseries, and charmingly natural they appear when thus placed, but notwithstanding which they may be grown and flowered equally well in small colonies on an even surface in spongy peat and sphagnum moss. To these I could add many more instances, all, however, having a similar bearing—viz., that elaborate and expensive rockeries are not absolutely necessary for the successful culture of alpine plants in the lowlands, but I fully realise the value of well-constructed rockeries, which, however, are anything but numerous. Heaps of stones, a disgrace to the name of rockwork, may occasionally be seen upon which alpenes cannot thrive, and the only one in nursery gardens known to the writer is that in the York nurseries. This is worthy the name, a veritable specimen of natural rock, and while such a one cannot easily be imitated, there are other means of forming and constructing such places as suit the majority of alpenes in most gardens.—E. JENKINS.

(To be continued.)

THE annual general meeting of the NATIONAL AURICULA and NATIONAL CARNATION and PICOTEE SOCIETIES will be held, by permission of the Council of the Royal Horticultural Society, in the Conservatory, South Kensington, as soon after twelve o'clock as possible, on Tuesday, December 8th, 1885. The business of the meeting will be the election of officers and Committee, receiving the Secretary's and Treasurer's report, the election of Judges for the ensuing year, and any other necessary business as may pertain to the annual general meeting.

—A GRAND SHOW OF ORCHIDS AT BIRMINGHAM is announced

to be held in the Botanical Garden, Edgbaston, on Wednesday and Thursday, May 12th and 13th, 1886, when prizes to the amount of £141 will be offered in eleven classes. The first five are for groups of twenty, ten, and six plants for nurserymen and amateurs, and in the others *Odontoglossum*, *Cattleyas*, *Laelias*, *Masdevallias*, and cut Orchid flowers are provided for. The Hon. Secretaries are William Southall and Hugh Nettlefold, Esq.'s.

—ONE of the best stove flowering plants of recent introduction is *AMASONIA PUNICEA*, for which plant cultivators are indebted to Messrs. J. Veitch & Sons, Chelsea. It has been shown and certificated at most of the leading exhibitions this year, and has attracted much attention, owing to its distinctness and beauty. It lasts in good condition for a surprisingly long time, plants having been in flower for over three months at Chelsea, and there are several now which have by no means lost all their attractions. The chief beauty resides in the bright red bracts which accompany the yellowish tubular flowers in long terminal racemes, the leaves being elliptical, dark green, and bold in appearance. One very good quality must not be overlooked—namely, it is most easily grown and propagated, and there is no doubt it would make a most effective specimen for exhibition.

—WE are informed that the Directors of the GLASGOW AND WEST OF SCOTLAND HORTICULTURAL SOCIETY have fixed their 1886 Exhibitions to be held in the St. Andrew's Hall, Granville Street, Glasgow, as follows—Spring, Wednesday, 24th March, 1886. Autumn, Wednesday, 8th September, 1886.

—MR. W. MONK, Forest House, Leytonstone, writes:—"I wish to thank 'D., Deal,' for his remarks on page 468 in favour of the TRAINED SPECIMEN CHRYSANTHEMUMS at the Aquarium Exhibition. I am glad that someone has spoken out in favour of the cultivation of Chrysanthemums in pots, because Mr. Iggulden last year wrote to say that they are not wanted at the shows and ought not to be encouraged. In my opinion a show without good specimen plants is not worth visiting."

—AT the NORTHAMPTON CHRYSANTHEMUM SHOW we are informed that Mr. W. A. Walter, gardener to Alfred B. Loder, Esq., was very successful in the open classes for cut blooms, taking second for twenty-four incurves, first for twenty-four Japanese, and in Class A, for gardeners within a radius of thirty miles of Northampton, he obtained second for twelve Japanese, distinct, second for six, one variety; first for twelve incurved, distinct; first for six, distinct; first for six, one variety, first for six, *Anemone*; and first for six, reflexed; Mr. Underwood Delapré Abbey, and Mr. W. S. Miller, Whittlebury, taking the remaining prizes in the same classes in the order of their names, with the exception of twelve Japanese and six one variety Japanese, where Mr. Underwood was first with good blooms.

—MR. C. WARING writes:—"At the NEWPORT HORTICULTURAL SOCIETY'S SHOW, Monmouth, held on the 19th inst., I gained the second prize for Japanese Chrysanthemum cut blooms; they were from cut-down plants grown for decoration only. In your report of the Show my employer's name should be Mrs. J. Aikin, it is misprinted Atkins."

—"G." sends the following paragraph—"THE APHIDES have hitherto been supposed to be the most prolific of living beings; and it is disappointing to find a writer who has been at the pains to count the progeny of a single Rose aphid, declaring that the individuals only number 32,768,000,000,000,000,000. He, no doubt, did not take a fair sample of aphids, and we hope he will try again with a result that will do more justice to this interesting insect. If he would also take the trouble to write the result in words instead of figures, he would gratify many persons."

—MR. W. F. BATEMAN, Kents Bank, Carnforth, writes:—"As an evidence of the MILDNESS OF THE SEASON, a swallow was seen flitting about over the ornamental water at Grange-over-Sands this afternoon; the bird seemed to have a remarkably fine coat of feathers, and there seemed plenty of food in the shape of insects in the air."

—"ENTOMOLOGIST" writes in reference to APRICOT BRANCHES DYING:—"Some few years since examples of branches that had perished from an insect depredator were sent to me for examination. The wood had been tunnelled by the larvæ of a clearwing moth, the special foe of the Pear twigs and wood—viz., *Sesia myopæforme*. I have not been able to hear of any similar instances, but as the species once occurred on the Apricot it might do again. Should you hear of any

case of Apricot failure where there is reason to suspect this insect may be concerned I would like to know about it."

— AN interesting description of a HYBRID PALM was recently given in the "Revue Horticole," by M. Carrière. It appears that a cross was obtained some time ago between *Chamærops humilis* and *Phoenix dactylifera*, the former being the seed-bearing parent. This was named *Microptœnix decipiens*, and when it flowered it was crossed with *Chamærops excelsa*, thus making the hybrid the seed parent. This experiment also proved successful, for plants of an intermediate character have been raised, upon which the name *Microptœnix Sahuti* has been bestowed in honour of the raiser, M. Sahut of Montpellier.

— THE *Tropical Agriculturist* remarks:—"The good people at home seem to be uncommonly bothered by the two products CACAO AND COCOA NUT. An English firm, who have made a specialty of 'Ceylon chocolate,' illustrate their advertisements of it with the picture of a man climbing a Coconut Palm and throwing Cacao Beans down to the gatherers below!"

— MR. R. MORSE, The Lodge, Cotham House, Tyndalls Park, Clifton, Bristol, writes:—"Allow me to correct a mistake in the report of the BRISTOL CHRYSANTHEMUM SHOW in the Journal of last week. It is stated that table plants were shown in great numbers, the majority of them being highly meritorious. Mr. W. Bannister, gardener to H. St. Vincent Ames, Esq., was first. It should have been Mr. R. Morse, gardener to S. Budgetts, Esq., first, Mr. Bannister not being awarded a prize in the class for table plants."

— A CORRESPONDENT writes to an Indian paper as follows on WOODEN LABELS FOR TREES:—"The following method of preserving wooden labels that are to be used on trees or in exposed places is recommended:—Thoroughly soak the pieces of wood in a strong solution of sulphate of iron; then lay them, after they are dry, in lime water. This causes the formation of sulphate of lime, a very insoluble salt, in the wood. The rapid destruction of the labels by the weather is thus prevented. Bass mats, twine, and other substances used in tying or covering up trees or plants, when treated in the same manner, are similarly preserved. At a recent meeting of the Horticultural Society in Berlin wooden labels thus treated were shown which had been constantly exposed to the weather during two years without being affected thereby."

— IN a colonial contemporary Mr. J. E. Taylor, Editor of "Science Gossip," thus refers to the BRACKEN FERN IN AUSTRALIA:—"This seems to be as great a nuisance to the agriculturist of these parts as the rabbits are to the squatter. The rich volcanic soils feed it well, and it spreads and develops accordingly. It costs a good deal, both in trouble and money, to keep it down. Burning the Fern only seems to make it grow more luxuriantly next year; chopping the 'roots' apparently tends to spread it. The so-called 'root' of the bracken is in reality an underground stem, or rhizome, the same part which in the Tree Fern we regard as the trunk. Within this stem, under ground or above ground, there is stored each year a supply of starch and other plant food. Every year's fronds contribute to the supply. The young opening fronds draw upon the vegetable banking account until they are fully developed, and then they repay the parent by contributing towards the stored-up supply in the stem. It is evident, therefore, that if we cut or mow down the young, half-coiled fronds of the bracken, just at the time when they are developing, and when they have been abstracting the nourishment from the stem, the latter will be impoverished. If we mow them down year by year the stems must wither and die. This may seem a rather tedious process, but in a few years it would prove an effective one."

WELLINGTONIA GIGANTEA.

THIS noble tree is well known in many gardens, but it is more frequently seen in extensive pleasure grounds than in small gardens, and there is no reason it should not be planted in both of these as much as in the former. Some Conifers and trees are more suitable for open positions than others, as they have a habit of spreading more than ascending, but the Wellingtonia is not one of these, as it is really narrow in its proportions at the base, considering its height. We have some old and young trees of it here, and both are very ornamental. The largest is nearly 60 feet in height, and its stem 3 feet from the ground is 13 feet 9 inches in circumference. Two years ago this specimen produced many clusters of cones near the top, but these have fallen, and recently numbers of cones have formed on the lower branches. There is another specimen a short way from this, equally high, but not so thick, and it is sterile.

Both of these have had the shelter of other trees for a considerable time, or indeed throughout all their young days, but for some years past their props have shot above this protection, and as they are now subject to some strong gales from the sea I fear they will not go much higher. The young specimens were planted by Royalty four years ago. They were 18 inches high when planted. One is now 6 feet 6 inches, and the other 9 inches less. From this it will be seen they grow moderately quick, and from first to last they retain a beautiful symmetrical outline and conical form. It would be unwise to plant them so near the edge of a walk that the branches would intrude in a few years, but if they are kept 10 feet or so from the edge there is little danger of their doing this. They are not over-particular as to soil, but succeed best in a deep loam, or position free from a predominance of stones. I have seen some very good specimens growing in ordinary garden soil.—J. MUIR, *Margam*.

PEAR TREES AT CARDIFF CASTLE.

WHEN on a visit to Cardiff Castle gardens, over which Mr. A. Pettigrew presides with such marked ability, we were very much impressed with the fine healthy appearance of the Pear trees, and the conclusion self and party of practical gardeners arrived at was, that taking all things into consideration a finer lot of trees could not well be found. For my part, I very much question whether another such a collection of about the same age is to be seen in this country, and as Mr. Pettigrew kindly favoured me with a few of the principal details of his practice with them, these I now place before the readers of the *Journal of Horticulture*. The kitchen garden walls are furnished with horizontally trained trees, while several of the long open borders are occupied with rows of pyramids, and in each case there was much to admire, especially seeing it had only taken ten years to bring them to such a profitable size. Mr. Pettigrew started with maidens, or unpruned and untrained trees, in each instance, those intended for pyramids being planted at a distance of 6 feet from the Box edging, and 14 feet apart. Early in the winter they were cut down to within 18 inches of the ground, and in the following spring they broke well, eventually ripening from three to four strong shoots, which were shortened at the early winter pruning to 2 feet from where they started, leaving the central or leading shoot a little longer than the others. This system of pruning was practised, leaving more or less growth according to circumstances, till the trees were well furnished, after which all the growths not required to fill the tree were spurred in regularly at the autumn pruning, but the principal branches are not shortened unless badly ripened, in which case the plan is to cut to a good bud.

It may here be stated that Mr. Pettigrew does not favour the practice of constantly pinching and stopping the young shoots during the summer, but to quote his own words, "all the pruning of pyramids is done, if possible, in the autumn and before the new year," and he further added that "the trees have been in fine bearing condition for some years, and all that is required to insure good crops is good weather when they are in flower." That his practice is the right one anyone who has seen the trees must admit, and at the time of my visit many of those grand specimens were so heavily cropped as to need props to support the principal branches.

The trees are planted in sorts, or from three to nine of each, and they have grown from 12 feet to 20 feet in height, and from 5 feet to 12 feet in diameter, each tree in a good season being capable of perfecting from 3 to 5 bushels of fine fruit. The following are the principal sorts grown, with the dimensions of a few of them—The trees of Pitmaston Duchess are among the best in the garden, each of the nine trees averaging 20 feet in height, and 12 feet through near the ground. They flower very freely every year, but generally get nipped by the frost, the consequence being rather short crops of very large fruit. On a south wall it crops remarkably well, and the fruit are found of excellent flavour. Williams' Bon Chrétien have attained a height of 14 feet, and are 6 feet through, the trees rarely failing to bear well. Beurré Clairgeau is of columnar habit, growing to a height of 14 feet, and only 5 feet through. It is not found a good bearer as a pyramid, but is an enormous cropper on a south wall, though the variety scarcely merits so good a position. Glou Morceau is about 14 feet high and 8 feet through, and is fairly profitable as a pyramid, while Easter Beurré has attained a height of 10 feet and 6 feet in diameter. There are several very handsome trees of Louise Bonne of Jersey, and these are about 10 feet high and 8 feet through. It is found to be one of the most free-bearing sorts in cultivation, besides being handsome and of excellent quality. Marie Louise Neaville has grown to a height of 10 feet, and about 8 feet in diameter, generally bearing well. Beurré Superfin also forms a good pyramid, and is very free-bearing and good in quality. These trees are about 10 feet high and 6 feet through. Duchesse d'Angoulême, another free-bearing sort, is 12 feet high and as much through, while Beurré Diel has attained a height of 20 feet and 8 feet through, usually cropping well. Beurré d'Amanlis are about 12 feet high and 10 feet through, and is a wonderful cropper, the quality also being much liked. Jargonelle this season perfected enormous crops, and these trees are 14 high and 10 feet through. Marie Louise has grown to a height of about 12 feet, and about 10 feet in diameter. The six trees of Bergamotte Esperen are fully 12 feet high and 8 feet through, and this was also carrying exceptionally heavy crops. This does not complete the list of varieties grown as pyramids, but enough are given to enable my readers to form some idea of the style of trees so rapidly created.

For furnishing the walls, 12 feet in height, the maidens were planted 21 feet apart, and the whole of the space is now occupied. They were

pruned at first to within 14 inches of the ground; these also broke well the following spring, and three well-placed branches were allowed to grow—two, one on each side, being trained horizontally on the wall, and the other perpendicularly. This central shoot was shortened at pruning time, leaving from 18 inches to 20 inches of new wood, according to circumstances, and the following spring the three shoots again selected and properly laid in, this going on annually till the top of the wall was reached. In this manner a fine clear main stem was secured, this in every case being well and regularly furnished with horizontal branches. The latter are never shortened till their limit is reached, unless it happened that they were not properly ripened, when it was considered necessary to cut to where it was ripened. Mr. Pettigrew, while the trees were young, examined them when they were starting in the spring and removed "two or more buds from the points of the permanent branches," this naturally strengthening the central or most important break. Root-pruning is also resorted to when it is required in order to bring any of the trees into good bearing order, and it is almost needless to add that all the trees are on the Pear stock, and that the soil is of a character to favour fruit culture, though this does not in the least detract from the merit of the achievement.

The following sorts are preferred by Mr. Pettigrew for wall culture, and most of the sorts can be relied upon for fruiting in even less favoured localities—Jargonelle, Williams' Bon Chrétien, Marie Louise, Doyenné du Comice, Fondante d'Antoine, Pitmaston Duchess, Gansel's Bergamot, Brown Beurré, Duchesse d'Angoulême, Benrre Bosc, General Todleben, Beurré Clairgeau, Glou Morceau, Beurré Diel, Josephine de Malines, Crassane, Knight's Monarch, Chaumontel, Winter Nelis, Ne Plus Menris, Bergamotte Esperen, and Easter Benrre.—W. IGGULDEN.

CHRYSANTHEMUM NOTES.

CHRYSANTHEMUM CULLINGFORDI.—The Committee of the Kingston and Surbiton Chrysanthemum Society met last evening and fixed Tuesday and Wednesday, November 9th and 10th, as the date of next year's exhibition. They had also brought under their notice as to whether we should admit the new variety, Cullingfordi, in the Japanese classes. Apart from its character as a type of Japanese or reflexed, it was pointed out that if we confined it to the reflexed class we should limit its cultivation as an exhibition variety, for we should lose it in the specimen plant classes, as we have no provision for reflexed varieties in those classes, the prizes being offered for incurved or Japanese respectively. It might be said, Why not admit them with the incurved and say, "large-flowered varieties, Japanese excluded?" Then growers say, "Judges have such a weakness for incurved that a man that shows a reflexed in a class stands at a disadvantage, other points being equal." The variety under notice seems such a good grower that it is the general opinion it will make a good specimen Japanese and be a great attraction on account of its high colour. Then as to its character. Knowing the point was going to be discussed, I produced the two blooms enclosed, the one fully expanded flower of Cullingfordi and the other a reflexed variety, Stevens' Sulphur Gem, a variety raised by Mr. Stevens of Putney and sent to me for trial. The latter is a good type of a reflexed flower, quite different from the Christines and other so-called reflexed varieties. Cullingfordi resembles in size and shape the character of Elaine, but if anything the florets are more erect than that variety, and it has their beautiful golden colour on the reverse side of the florets so characteristic of the Japanese, and that is not to be found in King of the Crimson or other dark reflexed varieties. The opinion of the Committee was that if we excluded this variety on principle we should have to exclude Elaine, Triomphe du Nord, and others, and at some future time there may be enough to make a separate class for Japanese reflexed, as we have done the Anemones, but that time is not yet come, so the Committee passed a resolution and decided to recognise it as a Japanese.

I have sent you the two blooms. Will you give us your opinion on the subject? You will allow, of course, for the reduction in size of Cullingfordi through being a stale bloom and also the loss of colour. This grew in an 8-inch pot and carried five flowers. I have one now in a 6-inch pot measuring just 2 feet high, including pot, and carrying a bloom as large as this one. So with a better start another year I think it could be grown larger and will look well in a stand of Japs.

I see Mr. Castle has not included in his list the first-class certificate I had for Cullingfordi at Kingston. I should have had one at the Palace, but it was certificated there last year.—C. ORCHARD.

[In view of two conflicting decisions on this subject we prefer to wait the issue of events.]

NATIONAL CHRYSANTHEMUM SOCIETY.—A considerable number of blooms were submitted at the meeting on November 25th, the principal exhibitors being Messrs. Cannell & Sons, N. Davis, R. Owen, Veitch and Sons, and W. Wright (Temple Gardens). First-class certificates were awarded for the following:—

Beauty of Swanley (Cannell).—A large full Japanese flower; colour rosy blush, suffused purple, with erect fluted florets.

Belle Paule (N. Davis and R. Owen).—A magnificent Japanese variety of recent introduction; colour white, heavily edged with bright lilac purple.

The following were highly commended for decorative purposes:—

Sulphur Gem (G. Stevens).—A sulphur reflexed flower in the way of Annie Salter.

La Favorite (Veitch and Cannell).—A hybrid Pompon; colour bright rosy pink.

Ruhrum Perfectum (Davis).—Pompon; very rich crimson.

Mdlle. Melanie Fabre (Wright).—A reflexed Japanese, likely to prove a very useful variety; colour rosy peach.

Mr. N. Davis called the Committee's attention to blooms of Cullingfordi submitted by him to test their opinion as to the class in which the variety should be shown, and it was unanimously resolved that it should be classed as a reflexed flower. The next meeting of the Society is Wednesday, December 9th, at the Royal Aquarium.

CHRYSANTHEMUM BELLE PAULE.—This fine Japanese variety will, when it becomes plentiful, be a great favourite with exhibitors. Its fine shape and colour, pure white with lilac edges, is very distinct from any Japanese variety I am acquainted with; it very much resembles Fair Maid of Guernsey in foliage, wood, and habit, which is no small point in its favour.—C. PAGE, Fern Lodge, Bracknell, Berks.

CLONMEL CHRYSANTHEMUM AND FRUIT SHOW.

NOTWITHSTANDING the prevailing depression which unfortunately affects every interest and the political excitement, Clonmel and vicinity, thanks to a few spirited gentlemen, has come to the front and held its first Chrysanthemum, though not its first fruit Show, on the 26th ult. You must permit me to specially mention the Committee who commenced the good work, the premier reference being due to the Honorary Secretary, Thomas Phelan, Esq., Spring Gardens; Frederick Clibborn, Esq., Anner House; and H. S. Boyd, Esq., Suirmount. These gentlemen formed, the managing Committee, and had associated with them George Gould, Esq., Birdhill, and Capt. Bagwell, D.L., Marlfield, all near this town. There were three sections in the schedule—plants in pots, cut blooms, and fruit divided into six classes. As notice of the intended Show was only published less than a month since, the Committee, to invite competition, decided to commence modestly, and have no reason to complain of the result.

In the class for six plants in pots there were four handsome well-bloomed groups, not trained, yet very floriferous and decorative. First F. Clibborn, Esq., (gardener, Mr. P. Crowley); second G. Gough, Esq. (gardener, Mr. T. Bulfin). Next came the cut bloom section, the incurved and Japanese being separate classes. The first prize for the best twelve incurved went to Thos. Phelan, Esq., with the following varieties really well done—Empress of India, Golden Empress, Lord Wolseley, Mr. Bunn, Lady Hardinge, Jeanne d'Arc, Nil Desperandum, Golden Queen of England, Princess of Wales, Bronze Jardin des Plantes, Alfred Salter, and White Venus; set up, naming from left to right—Empress of India was of immense size, and fully 5 inches deep. Mr. Phelan's gardener is P. Halpin, but the plants received his own close supervision; Mrs. Malcomson (head gardener, Mr. J. Crehan) was a good second, having the aforementioned blooms except the Rundle family, that rarely come near the others in size, no matter how well done. Fine blooms were shown by Mr. Clibborn, but they were too far gone, and lost points in that way. There were five entries all creditable. Next came the Japanese, around the stands of which was a buzz of excitement all day, and again when illuminated in the evening. Again Mr. Phelan came easily first with large though perfect blooms that would probably take a prize at any show in the kingdom. His stand contained the following dozen typical distinct varieties, naming from the left. Top row—Mons. Astorg, Mdlle. Audiguier, Comte Germiny, J. Delaux; second row—Rubrum striatum, Lady Selborne, James Salter, and Curiosity; front row—Bouquet Fait, Golden Dragon, Simon Delaux, and Peter the Great. Great difficulty was experienced in deciding between the next three entries, Messrs. Boyd's, Clibborn's and Crehan's, the former ultimately winning by two points. He had nine new varieties of last year's introduction, but with one exception Mr. Phelan's top row plants were of great size, especially Mdlle. Audiguier and J. Delaux, in fact the whole dozen varieties seem thoroughly reliable all seasons. The exception alluded to was two immense blooms, perfect in every particular, in Mrs. Malcomson's stand of Agrements de la Nature, within a fraction of 9 inches in diameter. All the exhibitors in this class could just as readily stage two dozen distinct varieties; and for non-competition to compete the display, Mr. Phelan staged, all told, four dozen distinct varieties of cut blooms; Mr. Clibborn three, and an equal number from Mr. Boyd, without counting those sent in pots or for decorative purposes.

The next two classes, as might be expected, did not attract much attention—viz., twelve reflexed and Anemone-flowered, and a similar number of Pompons in bunches. Messrs. Boyd and Phelan, already named, divided the honours, first and second, in the order named between them. The newer introductions of the Fabian de Mediana type and three new fimbriated varieties in Mr. Boyd's stand were much admired. The first prize in the amateurs' class for a dozen "any variety" went to Mrs. Jellico, Cahir. Lastly, in this section came the disposition of a large silver medal, offered by Messrs. Saunders, Friars Walk Nurseries, Cork, for the best collection of Chrysanthemums in the show. This deservedly went to the indefatigable Hon. Secretary, Mr. Phelan. Before passing to the fruit department it may be mentioned the Show was held in the spacious ballroom of the Court house, the stands and tables being draped with scarlet cloth, and the walls festooned most artistically with white and crimson wreaths. A large central table was charmingly arranged with Palms, Cycads, Bamboos, Poinsettias, &c., down the centre; Orchids, Dracenas, Crotons, and Maidenhair Ferns, then gradually sloped down to the stands with the best taste, while from the vestibule outside sweet music was discoursed by the fine Militia band of local Artillery. The prizes in the fruit section were for "the best collections." Mrs. Malcomson (Mr. Crehan) won easily first prize with Melons, two varieties of Grapes, and large collections, two dozen varieties of Pears and Apples, each kind. Second prize went to Captain Bagwell (Mr. Cleary, gardener) for five dishes of Pears, Apples (kitchen and dessert), Nuts Medlars, &c. The other exhibitors were Mrs. Crean, Coolgreany, and the aforementioned Messrs. Boyd and Phelan. Thus commenced what, is hoped, will yet become one of the best provincial Chrysanthemum Shows. Mr. F. W. Burbidge, F.L.S. Trinity College Botanic Gardens, Dublin, was one of the Judges, but missed his train; Mr. D. Saunders, Friars Walk, Nurseries, Cork, another, was detained by press of business; and in their

unavoidable absence your correspondent had reluctantly to act alone.—
W. J. MURPHY.

ERIOBOTRYA JAPONICA (LOQUAT) FRUITING IN THE OPEN AIR IN ENGLAND.

BEING much interested in your reply to "Medicus," page 414 in a recent Journal respecting the above plant, I beg to enclose for the Editor's inspection a leaf from a plant growing against a south wall (front of the mansion here, six miles from Tunbridge), also a seed from one of the fruits which ripened in the latter part of September of this year. The plant has been in its present position for probably over fifty years. We have an old workman employed in the gardens who has been on the estate nearly forty years, and he has no recollection of its being planted.

This is the first time that the tree has been known to fruit, and possibly it would not have been observed this season had it not been accidentally observed by a lady from an upper window. The form of the fruit much resembled a small summer Pippin Apple, both in size and colour. If the above simple statement requires further authentication, I would refer to my worthy employer, who first called my attention to the beautiful shining yellow fruit peeping out from among the large dark green foliage. I noticed, when at Linton Park four or five years ago, Mr. Groom, one of dear old Robson's successors, had several fruits on a plant under glass, but I have not before seen the fruit of this country's produce, although I have been constantly gardening for the past thirty years from beyond John o' Groats southwards.—WM. CHISHOLM, *Oxon Heath Park Gardens, Tunbridge, Kent.*

[The leaf sent was very fine, 1 foot long and 5 inches broad, proving the plant to be in vigorous health.]

THE ONION FARMS OF OHIO.

AN American paper gives the following description of the most extensive Onion farms in the United States. Ohio has four remarkable "Onion beds," Berea, Perry, Kinsman, and Aurora, but those at Berea are the most noted, and at Perry the most scattering, for anyone can raise Onions in the latter place. In a general way the practices at Berea govern all the rest. Onions have been raised there as a special crop for at least twenty-five years. The cultivation has never been abandoned on any of the farms, but, on the contrary, has gradually increased, so that the original fifty acres has now spread over five times that area. The first Onion lands were located about the margin of a marshy lake, known locally as Lake Abram. In years the farm has been extended by clearing, the lake has been drained down to less than one-third of its size, adjoining swamps have been cleared out and Onions planted, and even the uplands have, by modern ideas of fertilising, been made to yield profitable crops of Onions. Along Rocky River occasional "pockets of muck" are found. One of the most noticeable of these is the farm of Dr. D. T. Gould, located among encircling hills, and so completely drained that the floods and disasters that so often overtake the owners of the low farms never trouble him, and it is on this that some of the most interesting problems relating to Onion culture have been solved and some of the mysteries cleared up, as will be shown further on.

The great Onion farm comprises nearly 200 acres. It is composed of the richest and blackest of vegetable mould, from 4 to 25 feet in thickness, and completely free from clay, and shows but little if any disposition to turn to clay. The soil packs fairly well, and sufficiently not to blow away, except on rare occasions. The water line of constant moisture does not vary much from 2 feet from the surface, and fairly dry seasons are therefore more to be desired than feared. The danger is of too much water. The discharge, or outlet of the lake, finds no fall for over two miles, and a freshet is liable to cause the lake to overflow its boundaries and submerge the Onion lands, once its natural bed; this season three inundations occurred. But the drainage and lay of the fields are all made to conform to certain rules, and the damage is not as great as one would suppose. The farm is traversed at stated distances with wide ditches, often planked like a flume, and these are again crossed and recrossed by smaller ditches and underdrains. At the foot of the low hills that surround the basin huge canal-like ditches with their inside embankments, looking very warlike, are dug going to the river, and these keep out the hillside brooks and the rainfall from the high lands, and convey it away to the streams.

The division of the land is a matter of curiosity to the visitor, whose ideas of line fences are associated with rail and wire. The farm at Berea is owned by about forty persons, but as about six acres is the largest area of crop controlled by one man, the growing of the crop is thus farmed out to hundreds of renters, who occupy from one-fourth acre up to two or three. The rental is half of the crop, one to furnish muck and fertility; the other the seed and labour. The land is rarely rented for a monetary consideration. The Onions are made to pay rent, and the owner and renter thus share all successes and failures. Onions fluctuate so in value one year with another that it is hard to say what rent amounts to, but probably one year with another 100 dollars per acre is about the sum received from the rent. These lands are not for sale; they cannot be purchased, and if they could speculators would gladly purchase them at 1000 dollars per acre as an investment.

Once these lands were supposed to be of inexhaustible fertility and would never require any artificial aid, but now well-rotted manure, ashes, bonemeal, limekiln waste, &c., are used in great quantities, and the principal office of the soil seems to be a receptacle for the fertility, and agent to change it into plant food. Less manure is used each year, and more purchased fertilisers. The adding of great quantities of manure tends to lighten the soil, and the object is to make it as compact as possible without interference with rapid working. There is already enough vegetable matter, and will be for years, and the crop better responds to concentrated manures, like bone meal, &c. Deep working is also objected to. A few years ago it was argued that deep turning would be advisable, but now no one recommends it, and surface-stirring of the soil is only practised. Spring harrows,

notably the Whipple, are held in great favour, as they stir all the soil, leave no unworked places, and do not clog. The oblique set of the teeth seem to perfectly prepare the soil, and when the roller has followed nothing seems to be desired.

CYPRIPEDIUMS IN VINERIES.

CAN any of your correspondents recommend a *Cypripedium* which will make a good companion for *C. insigne*, which does well with us? It flowered in the spring, showing two flowers on one stem, and is in bloom again this autumn with seven stems. We have only one house, which has to do duty as a vinery; it has a rockery built against the back wall and planted with Ferns, besides stages filled with Ferns in pots, *Adiantums* generally, which do well with us. Then in the autumn it is filled with *Chrysanthemums* in pots, which do fairly well. The house is 30 feet by 15 feet, is heated with a flue, and we use a little fire all winter, which keeps the house between 40° and 50°, according to the weather. The Vines start during March, and come on gently as the weather improves. Our Grapes (Black Hamburgs) always finish well and have a good flavour.

I shall be glad to see some remarks from Mr. Molyneux on *Chrysanthemum*-growing. I think he has set a good example to us young men as to what can be done by perseverance.—D. R. D.

GOODWOOD.

PLEASANTLY situated on one of the southern fringes of the famous South Downs and within four miles of Chichester is Goodwood, the charming Sussex residence of His Grace the Duke of Richmond, K.G. Goodwood does not boast a very ancient history, only dating from the early part of the last century, when the estate which previously formed part of the Manor of East Lavant came by purchase into the possession of the first Duke of Richmond, who built the greater part of the present magnificent residence. The name is, however, not altogether unknown, as it has gained a widespread celebrity on account of its famous race-course and annual races, and horticulturally for its grand specimens of Cedars.

The house is a magnificent example of the Grecian style of architecture, the massive columns supporting the portico at the principal entrance being of a very imposing character. The walls are built with small flints collected for the purpose from the neighbouring downs, and a very pretty effect is produced thereby. This noble structure occupies a grand position commanding extensive views of the surrounding country, including the seacoast from Worthing to Portsmouth, with the Isle of Wight in the distance, and is surrounded by a remarkably well-wooded and beautifully undulated park of 2000 acres. The park slopes gently southward, and as the visitor enters it from one of the southern entrances, and follows the bold sweeping course of the long and capitolly made drive, the scene before him presents one of the richest panoramas of sylvan beauty it is possible to behold. The magnificent specimens of Cedars of Lebanon and remarkable groves of *Quercus Ilex* rising terrace-like one above the other, a huge promontory of the Downs revealing its masses of chalk through the distant foliage, and the Pine-clad slopes stretching away to the verge of the horizon, recalled to our mind, as we gazed upon this scene, the lines of Milton, whose words faithfully portray its beauties as—

"A sylvan scene, and as the ranks ascend
Shade above shade, a woody theatre
Of stateliest view."

Nowhere, we are told on good authority, does the *Quercus Ilex* succeed so well as it does at Goodwood. Planted on the northern and eastern sides of the mansion, they form an excellent shelter to the latter as well as the gardens. There is a very large specimen of *Cedrus Libani* growing in the park, which has very few equals in size in the kingdom. This tree was planted in 1761, and has now attained a height of about 68 to 70 feet, and its principal branches measuring from 50 to 55 feet in length. This noble specimen was much larger in width, but time and heavy gales and snowstorms have dealt somewhat harshly with it and caused it to lose several of its large branches. Those who are interested in these fine specimens of Cedars of Lebanon will find a full page illustration of the one we have just described in that excellent and valuable work Veitch's "Manual of the Coniferae."

The principal front of the mansion opens almost immediately into the park. The ornamental grounds on this side are of very modest pretensions, being confined to a few beds within an ornamental iron fence. These beds are filled chiefly with sweet-scented flowers, such as *Heliotrope*, *Stocks*, *Mignonette*, and *Carnations*, intermixed with *Zonal Pelargoniums*, single *Petunias*, and *Salvia patens* in accordance with the wish of the Duchess. Hard by is a remarkably large and vigorous example of the Cork Oak (*Quercus Suber*) with its peculiar corrugated outer bark, and a number of other fine trees.

A very prettily designed conservatory in three divisions sweeps round in a graceful curve from the left of the principal front, and this is beautifully fitted inside and tastefully arranged with choice ornamental and flowering plants. As the family is only resident here in July and August, all the efforts of the gardeners are concentrated on the preparation of the best display during that time, and especially during the race week, when the guests amount to upwards of 200. Particularly conspicuous among the flowering plants in this structure were a large quantity of the beautiful blue and white varieties of *Campanula pyramidalis*. These are, indeed, most effective for conservatory decoration at the period we are

writing of and later on. The late Mr. Geo. Westland used to make a special feature of growing this *Campanula* for the early autumn decoration of the beautiful conservatory at Witley Court. *Bougainvillea spectabilis* was thriving and flowering splendidly in this cool structure. This beautiful climber is generally grown in too high a temperature, with the natural result—a paucity of flowers.

Situated at the back of the conservatory, and enclosed within a square hedge of Privet or Laurels, are the plant houses principally devoted to growing small foliage and flowering plants for table and house decoration. A couple of houses are more or less occupied with Orchids, many of which are very large specimens, and used a few years ago to be great objects of attraction at the leading shows at South Kensington and the Botanic, Regent's Park. Particularly noteworthy for size and healthiness were *Vandas insignis* and *cærulea*, *Aerides virens*, *Cypripedium Harrisianum*, *Dendrobium nobile*, *densiflorum*, *speciosum* and *Hilli*, *Cattleya labiata*, *Skinneri*, &c., with several species of *Oncidium*, *Anguloas*, and *Lælias*. One house is devoted to the lovely and chaste Amazon Lily (*Eucharis amazonica*), the whole of the plants being conspicuous for vigour; and we may mention, by the way, that the drying-off process is not practised here, an evident proof that an active and continued growth is the most rational method of growing these useful plants.

From the plant houses we are conducted to the lawn, which is pronounced by competent judges to rank with the finest examples of its kind in England. It is indeed a beautiful lawn, unblemished by garish parterres or beds, and its quiet beauty is greatly enhanced by the noble trees and shrubs which so artistically fringe its sides that extend for upwards of a mile, and form a vista of such exquisite beauty as only Goodwood with its rich arborescent treasures can do.

Leaving this charming lawn to our left, we pass along greensward walks beneath a canopy of foliage of gigantic Oaks, Cedars, Chestnuts, and Limes, until we come to the hermitage, an immense hollow Jell surrounded by old ruins, in which are a number of caverns, subterranean passages, rookeries and rockeries, and other features of a wildly picturesque description. One peculiar and noteworthy feature of the caverns was the fact of the floors being paved with horses' teeth, and the roofs and sides of univalves or beautiful samples of shells. Within a stone's throw of this weird-looking spot is the flower garden and arboretum, which occupies a position unequalled for beauty of surroundings. It is surrounded on all sides, except the south, by immense trees of *Quercus Ilex*, *Cedrus atlantica*, Chestnuts and Limes; towering up to an immense height behind these were lofty examples of the Scotch Fir (*Pinus sylvestris*) and Lombardy Poplars, whilst to the front were masses of *Rhododendrons*, *Azaleas*, and other shrubs, thus forming an amphitheatre of rich verdant foliage, which in addition to its great beauty forms an excellent shelter. Some very striking specimens of Conifers were thriving remarkably well here, notably *Wellingtonia* (*Sequoia*) *gigantea*, *Cryptomeria japonica*, *Cedrus Deodara*, *Pinus insignis*, and several others. There is, too, a large and lofty specimen of the Tulip Tree (*Liriodendron*), which must be very pretty when in full blossom. The beds are of simple design and few in number, and these are mostly filled with herbaceous plants, Lilies, and single Dahlias. There is one bed of Zonal Pelargoniums, and these have remained in the bed without lifting or protecting for three years, a conclusive proof of the value of the shelter afforded by the trees just mentioned. On the south side is an old wall, against which is a rustic framework of wood with a walk underneath. The sides and roof of this rustic woodwork are covered with the Traveller's Joy (*Clematis Vitalba*), and other species, such as *Jackmanni*, &c., *Jasminums* in variety, and climbing Roses, which grow in happy confusion, and form a very pretty bower, and is altogether an excellent plan for turning an otherwise unsightly wall into a very pretty object. In front of this are two long herbaceous borders divided by a walk, and in these are such showy hardy plants as *Rudbeckia Newmani*, *Pentstemons*, *Antirrhinums*, *Delphiniums*, *Statice*, *Carnations*, and *Campanulas* in variety. Continuing our stroll through avenues and groves of trees, and other pleasant features of landscape beauty, we find ourselves back to the spot whence we started on our tour round the pleasure grounds. We have yet the fruit and vegetable gardens, as well as the forcing houses, to see, and to see these we have to go a considerable distance across the park, as the latter departments are a long way apart from the former.

The kitchen garden is of an extensive character—we forget the exact dimensions, and is surrounded by high walls built in the form of a parallelogram, and here, as in the pleasure grounds, the north and eastern sides are sheltered by the thick dense growth of the *Quercus Ilex*. Just inside the entrance gates is the spacious and comfortable-looking residence of the able gardener-in-chief, Mr. Rutland. The walls are covered with a capital and well-trained lot of fruit trees. Peaches do specially well here, as also do Nectarines. *Ansdén June* is a great favourite variety of Peach here, and Lord Napier among the Nectarines. We saw the trees of the latter variety heavily laden with large and high-coloured fruit. Another wall is devoted to growing the best varieties of Pears, most of which were carrying heavy crops of fruit. The remaining walls were covered with Plums and Cherries. A few large standard Apple and Pear trees were dotted about here and there, with a miscellaneous collection of bush fruits and Strawberries.

Vegetables, as might be expected in the case of such a large establishment, are grown on a large scale here, hence immense quarters of the useful classes of Brassicas, Carrots, Parsnips, and Beet are grown. In order to keep up a supply of Shorthorn Carrots during the winter sowings are made on a south border in the end of July and beginning of August. The young plants make little roots by the end of the year, and are then fit for drawing for use. The whole of the crops were looking

in the best possible condition of health, notwithstanding the excessive drought. We omitted when describing the fruit trees to mention how freely the large Fig trees bear and ripen their fruit in the open air there. Owing to the dry weather the fruit is not so large, neither did it ripen so early in consequence this season.

The forcing department, which occupies an open position in the centre of the kitchen garden, consists of several vineries, Peach houses, Pine stoves, Melon and Cucumber houses, and pits.

Grape-growing is well understood and carried out, as the records of the various leading shows will testify. But few Grapes were hanging on the Vines at the time of our visit, as the produce of several houses are consumed during the race week. A portion of a house of Mrs. Pince remained, the bunches of which were very fine and beautifully coloured. The whole of the Vines were in splendid condition, both wood and foliage testifying by their robust and vigorous appearance that they are looked well after here. Mr. Rutland adopts a capital plan of securing early Grapes, and which is well worthy of record. In a three-quarter span-roof house there is a pit about 4 feet deep on each side of the path. Each of these pits are half filled with a capital compost, and in this young one-year-old Vines are planted about 18 inches or 2 feet apart. The second year the Vines are left the length of the roof, and are allowed to bear a crop of fruit. The remainder of the beds are filled with compost, and this secures a heavy third crop the following year. It is worked upon the same principle as is adopted in the case of pot Vines, with this exception, that the Vines will bear heavy crops for three successive seasons, whereas in the case of pot Vines it is useless to attempt growing a second crop. Young Vines are kept constantly growing on, and should any of the canes exhibit any tendency to weakness from overcropping, after the second year they are replaced by the young Vines just mentioned. After the fourth year the old Vines give way to new ones with a renewal of the compost. We omitted to mention that the house is in two divisions, which enables the Vines in one house to be renewed whilst the other is bearing. This plan is decidedly superior to growing Vines in pots for early forcing, as the returns are greater in proportion to the expenditure and labour involved. We may add that the plan has been carried out with great success here for many years past.

Pines are grown well and in quantity; especially noteworthy were some grand fruiting examples of Smooth Cayenne, Charlotte Rothschild, and the Queen. In the Melon houses were some remarkably handsome fruits of that capital variety, Dr. Hogg, in their last stage of ripening. This is a favourite variety with the family. Many readers will remember reading an account a year or so ago of a gigantic Melon raised at Goodwood from seed sent home by Major General Drury Lowe from Egypt, and exhibited by Mr. Rutland at South Kensington. Peaches early and late are grown well under glass, as also are Nectarines, these being represented by veteran trees of large proportions of those capital sorts, Royal George Peach and Elruge Nectarine. Having completed our tour through the houses we return by way of a large roserie leading up to our guide's house, which, by the way, is nearly covered on one side by a large plant of that beautiful climber, *Passiflora cærulea Newmani*. This variety, which originated not far from Goodwood, is a very superior form of *cærulea*, and deserves to be more generally grown than it is.

We completed our tour of inspection by visiting the fruit garden, which is situated at a still greater distance from the kitchen garden than the latter from the flower and pleasure grounds. Owing to the departments being situated so far apart the duty of superintending these is not an easy one. The fruit garden is situated about two miles away, and occupies the site of an ancient garden attached to the mouldering ruins of a once princely residence—Halmaker Castle, formerly the property of the Derby family, but for some years now belonging to the Duke of Richmond. But little now remains of the Castle, which occupies a commanding position, except a few of its immensely thick outer walls. There is a fine avenue of ancient Spanish Chestnuts with gnarly stems, indicative of the attainment of a hoary and venerable age. Growing up into vigorous bushes, in the floors of the ancient hall and chapel, are a number of Filberts in strange contrast with the revelry of the one and the sanctity of the other in centuries gone by. Another strange feature was the sight of seeing a crop of Potatoes growing at a high elevation on what had originally been the floor of a bedroom. The outer walls still remain up to the original level of the bedroom floor, to which level in the course of time the falling *débris* has accumulated. On this a soil has been formed by the decomposition of vegetable matter, enough, with a little addition in fact, to grow the Potatoes just mentioned. In the old gardens and a small orchard adjoining there is a good collection of the very best varieties of culinary and dessert Apples, chiefly standards. On the walls are trained good varieties of Pears and Peaches. Plums, especially Victorias, were so heavily laden with fruit that every branch had to be supported by a prop. The situation of the orchard is high and very much exposed, and the soil and subsoil very stony. Notwithstanding this Mr. Rutland states that the trees bear freely, produce fine fruit, which is always beautifully coloured; and, moreover, the trees do not exhibit that tendency to grossness of growth which is so characteristic of trees grown in low situations. Samples of Apples grown here have never failed in competition at the leading shows to secure first honours.

I need only add that my visit was rendered a most pleasant one by the hospitality of both Mr. and Mrs. Rutland.—T. W. S.

PRUNING DENDROBIUM NOBILE.

I BEG once more to trouble you with a few remarks about *Dendrobium nobile*. You will remember I said all the old growths were cut

away from the two plants I had at South Kensington on the following day after I brought them home. These two plants have now finished their growth for this season. Though one of the plants stood in a dry room in London for more than a week without any water, and in consequence lost most of its roots, it has made splendid growths; in fact, I think, rather better than they were last year. I hope next spring to get some fine flowers from these growths. As some Orchid growers are slow to believe that it is possible to make growth and flower them in one season, I should be glad if those who are still doubtful would try for themselves what they can do. If any of the Committee who saw the plants at South Kensington would care to see them now, I shall be pleased to show them to anyone who will take the trouble to come.—H. C. PRINSEP.

SIR JOSEPH DALTON HOOKER.

LAST week we announced that Sir J. D. Hooker had resigned the directorship of the Royal Gardens, Kew, and as the time is an opportune one we now present our readers with a portrait of this gentleman, accompanied by a review of his career, which proves how well he deserves the world-wide fame he has won as an accomplished botanist.

Sir J. D. Hooker is the son of Sir William Jackson Hooker, and was born at Halesworth, Suffolk, June 30th, 1817, and is therefore now sixty-eight years of age, happily still in the enjoyment of good health and apparently none the worse for the exposure and fatigue he endured in his early travels. He was educated at Glasgow, and obtained the degree of M.D. from the university of that city in 1839. Very shortly afterwards Dr. Hooker commenced his active career as assistant surgeon in the Antarctic Expedition under the command of Sir James Clark Ross, and during three years' travels in the southern seas accumulated vast stores of knowledge relative to the floras of New Zealand, Van Diemen's Land, and other islands. The information thus acquired was embodied in "The Botany of the Antarctic Voyage," published in six volumes, the first in 1847 and the last in 1860, which forms a most valuable work of reference upon all points connected with the interesting vegetation of those regions. After performing the duties of botanist to the Geological Survey of Great Britain in 1846, Dr. Hooker in the following year set out on his memorable journey to the Himalayas, where he explored the Sikkim district, experienced many dangerous adventures, and greatly enriched our knowledge of the numerous charming Rhododendrons which are found in that country. A superb work, "The Rhododendrons of the Sikkim Himalaya," published in 1849 to 1851, contains a number of beautifully executed sketches of these handsome plants, which drew much attention to them, and a large proportion of the best species have been since introduced at various times. The collection at Kew now comprises most of the leading forms, and visitors to the temperate house in the pleasure grounds have often had occasion to admire the grand flowers of *R. Aucklandi*, *R. Edgeworthi*, *R. argenteum*, and others of a similar character.

In 1841 Sir William Jackson Hooker was appointed successor to Mr. W. T. Aiton as director of the Royal Gardens, Kew, and Dr. Hooker subsequent to his return from India—namely, in 1855—was appointed assistant-director in the same establishment. A botanical tour in Syria was undertaken in 1860, the principal subject of investigation being the native Oaks, and a paper embodying the results was read before the Linnean Society soon after his return. The death of Sir W. J. Hooker in 1865 led to the appointment of his son as successor, and he has most ably carried on the work of improvement commenced by his father, having placed Kew Gardens in the foremost rank as a scientific institution.

Much attention was attracted to the Darwinian views upon "the origin of species" and cognate matters by the eloquent opening address delivered by Dr. Hooker before the "British Association" at Norwich in 1868, and of which we gave a full notice in our issue of September 10th of that year (page 189). In 1871 Dr. Hooker, accompanied by Mr. John Ball, spent some time in botanically exploring Morocco, where a large number of plants was obtained and imported to this country. The most recent expedition was that to the United States in 1877, where he spent three months with Dr. Asa Gray, whom he assisted in the botany of the United States for the Government Surveys.

Numerous honours have most worthily fallen to Sir J. D. Hooker. At the Oxford Commemoration in 1866 the honorary degree of D.C.L. was conferred upon him, and in the same year he received the degree of LL.D. from the University of Cambridge. In 1869 he was appointed Civil Companion of the Order of the Bath. The Royal Society elected him President in 1873; this post he resigned in 1878, and in the same year the University of Dublin accorded him the degree of LL.D. In 1877 he was created Knight Commander of the Star of India for the services rendered to the Indian Government. The Society of Arts in 1883 awarded Sir Joseph Hooker the Albert Medal for "the services rendered to the arts, manufactures, and commerce by promoting an accurate knowledge of the floras and economic vegetable products of the Colonies and Dependencies of the Empire." The Royal Geographical Society also in the same year awarded him their founder's medal "for his eminent services to scientific geography, extending through a long series of years and over a large portion of the globe, while engaged in voyages in the antarctic and Australian seas, and journeys to India and Himalaya, in Morocco and in the United States of America, and more especially for his long-continued researches in botanical geography, which have thrown light on the form of the land in prehistoric times, and the causes of the present distribution of the various forms of vegetable life on the earth."

Several of Sir J. D. Hooker's works have been noticed in the course of the preceding remarks, but the others must not be omitted, as they rank amongst the most important botanical works published in this country.

The "Genera Plantarum," which was commenced in 1862, and which, with the aid of Mr. Benthams, was brought to a conclusion a year or two since, is an extraordinary production, necessitating enormous labour and care. The Himalayan Journals, two vols., published in 1854, contain interesting descriptions of travels in that region, and while of scientific value also possess much popular interest, being written in a free and agreeable style. The "Student's Flora of the British Islands" first appeared in 1871, and has now become the accepted handbook for amateur botanists who study our native plants. Another very popular work is the "Primer of Botany," which has assisted some thousands in mastering the elements of modern botanical science. The "Handbook of the New Zealand Flora" and the "Flora Novæ Zealandiæ (Cryptogamia)" are highly important and exhaustive works which have added greatly to the reputation of the author. In addition to these a "Journal of a Tour in Morocco and the Great Atlas" was published, together with several papers in the Linnean Society's "Transactions," and the able lecture on "Insular Floras," which was delivered before the British Association at Nottingham. The editorship of the "Botanical Magazine" has also been entrusted to Sir J. D. Hooker for some years past, and a valuable series of plates has been published during that time, including representations of many rare and beautiful plants which have flowered at Kew.

In 1874 the "Flora of British India" was commenced, and up to the present only three volumes have been issued, as owing to Sir Joseph's numerous official duties he has not hitherto been able to devote to it the time needed by such an undertaking. Now he intends applying the leisure which his release from office will afford to the completion of this important work. It might have been supposed that after such an active career, and with such a record, Sir Joseph Hooker would be content to rest, but with him, as with all true lovers of science, work must have been his pleasure, or he could never have accomplished so much.

In the great establishment, which has been under the directorship of Sir J. D. Hooker for the past twenty years, will also be found ample testimonies to his ability and devotedness to the advancement of botanical science on a broad foundation. Of special importance are the wonderful museums containing the economic products of the vegetable kingdom, the nucleus of which collection was contributed by Sir W. J. Hooker in 1847. Since then they have been enormously increased by the efforts of the retiring director with the help of innumerable friends and correspondents in all parts of the world, until these museums have become vast storehouses representing the uses of plants as food, medicine, clothing, ornament, and for many other purposes. The importance of this department is widely recognised, and additions are constantly being made, the transference in 1878 of the India Museum collection to Kew Museum increasing the latter by 4000 specimens, which have been carefully arranged with the others in their natural orders. As an example of how greatly the collection has been extended, it may be remarked that in 1847 one room sufficed to contain the whole of it, now three large buildings are devoted to it.

Another department which owes much to the Hookers, both father and son, is the Herbarium, which as a general collection of dried plants is unrivalled in the world. It contains large numbers of specimens collected by Sir Joseph Hooker himself, besides contributions from all the principal travellers and botanists who have wandered in search of plants in both tropical and temperate climates. It has become the centre of botanical knowledge not only of Britain but of Europe, and is resorted to by all the most distinguished naturalists of the day. This alone would have rendered Kew famed.

Many improvements have been effected during Sir Joseph's directorship and through his influence, which can only be briefly noted, but prominence must be given to the wonderful gallery of floral paintings presented to the gardens by Miss Marianne North, a monument of industry and skill which could not have found a more appropriate home than at Kew. The Jodrell Laboratory for botanical research is another institution of considerable scientific importance, in which much valuable work has already been performed. The surprising collections of living plants have been extended, better housed, and better cultivated, while the correspondence with colonial botanic gardens has been enormously increased with advantage to both; large quantities of Cinchonas, Guttapercha-yielding plants, and others of economic importance having been reared at Kew and exported thence to various parts of the British empire, where valuable plantations have been formed.

These are only a few examples of the work that has been done, but they will suffice to indicate how well Sir Joseph Hooker has earned his retirement.

HARDY PLANTS AT MALPAS.

IT was getting late in June when I had a few hours' enjoyment amongst the alpine and other hardy flowers at Edge Hall, where the generous owner, Rev. C. Wolley Dod, indulges his enthusiasm for the plants he loves so well. No wonder the place had such a wealth of beauty when we understand what pains are taken to develop the culture of hardy flowers, for after seeing most of the best collections in the country I confess I never saw anything equal to the wealth of interest there was at Edge at the time of my visit. To the lover of hardy flowers the collection is essentially an educational one, because Mr. Wolley Dod subjects the merits of the majority of his plants to a crucial test. They are cultivated with zeal, at the same time keen discrimination is exercised, so that while you see the choicest gems in the highest state of cultivation, weedy plants are extremely scarce; in fact, there are few plants encouraged which may not well be included in all collections. We often

observe Mr. Wolley Dod complaining about the climatic conditions of his immediate surroundings, but regardless of these, as well as the uncanny nature of the soil, he has with much patience and labour achieved a success which is rare.

Dotted about are some charming pieces of rockwork, happily accommodating the choicest rarities in unusual health, and mostly in good masses or colonies, so that every ledge or nook is replete with interest, the mere enumeration of which would crowd out too much other useful matter from the Journal. Special attention is given to certain series of plants; for instance, *Liliums*, *Aquilegias*, Alpine *Dianthus*es, and Cam-

variety of colour and form of flower, of course consistent with the vagaries of *Columbines*. Short, medium, and long-spurred, European and New World forms have united to produce a most interesting and beautiful series of intermediates. The species *cœrulea*, *vulgaris*, *chrysanthus*, *californicus*, *canadensis*, and others have all been utilised, and the result is a progeny alike for its differentiations and extreme interest, while for the hardy flower garden we can scarcely recommend anything so heartily. We noticed the true, but scarce, *A. Skinneri* and *A. canadensis* in very strong condition. Mr. Dod thinks this is the chief factor in producing the shades of red and orange predominating in many of his seedlings.

Fig. 75.—SIR JOSEPH DALTON HOOKER, K.C.S.I., F.R.S.

panulas, to say nothing of the most charming effect produced by the Poppies. Rarely have I seen a more striking example of flower gardening than a good-sized piece of rockwork pretty thickly dotted with most floriferous patches of the different varieties of *Papaver nudicaule*, amongst which goodly numbers of *P. umbrosum* were distributed, with its deep crimson flowers in association with the yellow, which, and shades of orange-scarlet of *nudicaule*, presented a unique picture.

AQUILEGIAS.

Turning, then, to the *Columbines*, we have a striking example of the value of these flowers of all gardens, provided they are liberally treated and rigidly selected. Every season the best flowers are selected and crossed if considered necessary for seed-saving, as a fresh batch is raised every season. The young plants are put in beds of rich soil early in the season, and by the following spring they are strong enough to bloom profusely. Although they were just past their best at the time of my visit, yet there was abundance of evidence of the high pitch reached, there being every

CAMPANULAS.

Amongst the *Campanulas* was a most instructive series of forms of *C. rotundifolia*, revealing much variation both as regards size of flowers, habit, and times of flowering. One form was especially fine, producing very large bells; indeed, apart from the others close by it, we might be pardoned for regarding it as some other species. Of course this series included some other so-called distinct species from southern and middle Europe, if my memory serves me well, but there was essentially no distinction between them and our wild *C. rotundifolia*, when studied in connection with what are evidently intermediates. There were also grand masses of *C. abietina* upon a small rockery in full bloom. To me there was a mystery about this, as I failed to get it to bloom satisfactorily, and have noticed it in at least three different collections flowering only very indifferently; but here the tufts appeared to be all flower-stems. The bunches of stems were at least a foot through, well furnished with the large light blue bells, and is certainly one of the best species for the rockery. I believe it was distributed by Gusmus of Austria. The rare

little *C. Waldsteiniana* was well represented, the greyish tufts being crowded with its charming little erect flowers; also *muralis* (*Portenschlagiana*), numerous forms of *garganica*, *pulla*, *pusilla*, &c.

LILIUMS.

The Liliiums were also a most beautiful feature and remarkably well grown, although but few of them were in bloom so early in the year, yet most of them gave excellent promise of a rich display. The Caucasian *L. Szovitzianum* was well in flower in different parts of the garden, some with very large heads carrying more flowers than I have previously seen under cultivation, but this is due to the very liberal treatment it receives, for its fare is sumptuous. A good supply of rotten manure with loam and a good dusting of bone dust is given at the time of planting, which evidently agrees with this Lily. *L. giganteum* is splendidly grown. There were four specimens with large flower-stems, and it is likely the largest would be 8 feet or more high and well furnished. It is a noble-looking plant even when not in flower, and is certainly quite hardy. It suffers most in early spring, when its tender foliage is frequently injured by frost; slight protection at that season meets its wants and it richly merits such attention. *L. Martagon album* and *dalmaticum* were showing well, also *Humboldtii*, the forms of *pardalinum*, and many others. The occupants of the Lily house looked exceedingly healthy and strong, and no doubt later in the season were well worth seeing. Some clumps of Christmas Roses in this house were well furnished, very large and healthy foliage. The masses of the Californian Lilies, which I took to be *pardalinum*, and perhaps some of its numerous forms, as well as *superbum* from the Eastern States were represented in strong masses in the bog bed, which is evidently the best place to grow, although as far as I remember this bed was not particularly wet and boggy. Perhaps it would be better to call it a peat bed maintained in a pretty moist condition.

ALPINE PINKS.

A word as to the charming series of Alpine Pinks represented in gardens and nurseries under the names of *D. alpinus*, *neglectus*, and *glacialis*. They were planted side by side, seedlings raised and flowered together, and certainly there was a striking resemblance between what are generally understood to be distinct species. The most striking difference at any time would appear to be in the foliage and the floriferousness; for instance, the foliage of *alpinus* is different to what is known as *glacialis* and *neglectus*, while both these are much more tufted in growth and free-flowering than *alpinus*; but such a series of seedlings as were in flower at Edge is certainly very convincing that at most only one species can be recognised, and that is likely to be *D. alpinus*. According to Mr. Wolley Dod's experience, these charming little Pinks are best raised from seed each season, as they are so liable to go off after flowering; but I must say that in this particular I have found *glacialis* and *neglectus* greater sinners than *alpinus*, which under favourable conditions grows freely into a large tuft and may be pretty easily increased by means of cuttings, which root freely in a cold frame.

ALPINE PLANTS.

The notes made of other meritorious alpinos upon the numerous rockeries are copious, but it will only be necessary to mention a few of the best for general cultivation—kinds, in fact, which every lover of alpinos may well covet. *Oethionema grandiflora* was crowded with flowers and formed a most conspicuous feature. The rare *Arnica montana* was quite at home, although rather a fastidious subject to establish. *Coronilla iberica* formed broad sheets of elegant foliage and golden yellow flowers. *Lychnis Lagasce* is a bright little species crowded with rosy pink flowers. A large number of the choicest encrusted *Saxifragas* are accommodated on small rockeries at the ends of the greenhouses, where there are some unusually fine examples of *S. longifolia*. *S. Macnabiana* was very fine upon another rockery; this is a beautiful variety, the flowers being crowded and copiously spotted it should find a home in all collections. The rare *Geranium argenteum* forms good tufts of its silky white foliage and blossoms well; it is only at Mr. Whitehead's of Bickley that I have seen it equal to those at Edge. The yellow *Dryas Drummondii* and the Arctic Bramble (*Rubus arcticus*) are quite at home, the former especially forming large masses. *Veronica pinguifolia* crowded with white flowers and glaucous foliage, convinced one that it is one of the best alpine shrubs we possess. The Himalayan *Cyananthus lobatus* was charming. The fleshy rootstocks are happy under a ledge, from which the pretty shoots are sent out bearing the blue funnel-shaped flowers; this alpine is much too seldom seen. *Onosma taurica*, *Linaria anticaria*, *Erodium Reichardi*, and a host of others were clad in their best dress, and constituted really a feast for those inclined to fancy them.

CHOICE HARDY PLANTS.

Other plants worthy of mention in the borders at the foot of and upon the walls are the "Horned Poppy" of California, *Romneya Coulteri*, which was in excellent health, showing flowers, and later in the year I saw flowers from the same plant exhibited at a local show; this is a plant well worthy much trouble to cultivate, although much is not required. *Primula sikkimensis* major was most conspicuous at the foot of a wall, with tall stout stems supporting very large umbels of primrose yellow flowers, so much superior to what one is accustomed to see that the form well deserves its majority. Harper Crewe's *Doronicum* is now well known; it is an invaluable plant for borders, especially the freely divided and replanted. *Armeria cephalotes* in several shades were very conspicuous. *Rosa rugosa* and its white variety are very showy shrubs both for rockeries and borders. *Erigeron aurantiacum* was splendid in a small bed, the flowers being very

large and highly coloured, it is really a good plant. The forms of *Lychnis viscaria*, both double and single, were effective; while a very different plant was found in *Ligularia macrophylla*, with massive glaucous foliage and tall panicles of yellow flowers, an unique plant. The Blue Poppy, *Meconopsis Wallichii*, was interesting but not over-attractive, nevertheless desirable. The Madeira Orchis *foliosa* is quite at home in the peat bed, while *Cypripedium calceolus*, *candidum*, and *spectabilis* were attractive at the foot of a wall; other species were, I think, past. *Ranunculus bullatus* fl.-pl. is an excellent double Crowsfoot, dwarf in habit, with large yellow flowers. *Allium neapolitanum*, *Pentstemon glaber*, *Cheiranthus Marshalli*, *Hieracium villosum*, *Chrysobactron Hookeri*, were vigorous and most effective, while *Asphodelus ramosus* as here represented, must be regarded as a very effective and desirable plant.

I am reminded in penning these remarks that a short contribution was published in the Journal a little over three years since upon the same collection, and as I had not visited the place between the time when those notes were made and last June, I was enabled to recognise what a marked improvement has been made in every way. Mr. Wolley Dod is indefatigable, and where three years since there was a good-sized kitchen garden I think it was only represented by a solitary Cauliflower, but there is ground beyond for vegetables, and long may the collection of hardy flowers be a source of enjoyment to its present owner. This rambling sketch I know is most inadequate, and conveys but a poor idea of its richness.—J. T. R.

THE LIVERPOOL SHOW.

NOVEMBER 24TH AND 25TH.

THE above Show was held in St. George's Hall, and proved equal in merit to those previously held by the Society. There was a slight falling off in the number and quality of the stove and greenhouse plants as compared with the exhibits of the past few years, but this is undoubtedly due to Mr. W. Mease having discontinued exhibiting. It would, however, perhaps be as well if Crotons and such tender stove plants were not exhibited at this season of the year, but provision made in the schedule for groups of *Chrysanthemums* instead. A little more provision for Palms would also be an advantage, and if arranged down the centre of the tables running the whole length of the hall the appearance of the exhibition would be materially improved, for the Exhibition just held had a flat appearance and was less beautiful in this respect than some previously held by this well-managed Society. The Show was a great success as far as the exhibits were concerned, but this cannot be said of the finances, as the first day was most unfavourable for visitors, being dark and very wet. The second was very little better in this respect, and, unfortunately, the Liverpool elections were held on this day. The anticipations of some that this would prove an advantage to the Society were not realised, for the opposite was the result.

CHRYSANTHEMUMS.

Cut Blooms.—These were more numerous than we have before seen them at this Society's Show, for the prizes offered were well contested in every class. The Japanese blooms throughout were remarkably fine, but the incurved were scarcely equal to those generally staged by the Liverpool growers. This may be accounted for by Messrs. Lindsay, Mease, and other leading exhibitors showing at Hull and other places this year. The blooms on the whole, however, were very creditable to the exhibitors. In the class for eighteen incurved and the same number of Japanese, distinct varieties, four collections were staged. The prizewinners in the order named were Mr. J. Jellico, gardener to F. H. Gossage, Esq., Camp Hill, Woolton; Mr. F. Roberts, gardener to W. D. Holt, Esq., Landsfield Park, West Derby; and Mr. T. Leadbetter, gardener to R. N. Dale, Esq., Bromborough Hall. The blooms of Japanese in the first and second collections were very close, but Mr. Jellico took the lead with his incurved blooms, which were larger in size than those of Mr. Roberts, while in freshness and colour they were about equal; Mr. Jellico, however, well won the silver cup given by Messrs. J. Williams & Co., 62, Mount Pleasant. The best of the incurved blooms were Empress of India, Golden Empress, Queen of England, John Salter, Lord Alcester, Jeanne d'Arc, Refulgence, Mr. Bunn, White Beverley, Lord Wolseley, Emily Dale, Princess of Wales, Barbara, Mrs. Heale, Jardin des Plantes, Cherub, Sir Stafford Carey, and Princess Beatrice; Japanese—Soliel Levant, Japonaise, Belle Paule, Comte de Germiny, Sarnia, Golden Dragon, Fair Maid of Guernsey, Mdle. Lacroix, Meg Merilees, F. A. Davies, Boule d'Or, Criterion, Elaine, Balmoreau, Madame C. Audiguer, Peter the Great, and Mons. J. Laing.

For twenty-four incurved, Mr. J. Jellico was again first with a capital stand of blooms, and noticeable amongst them were Empress of India, John Salter, Lord Alcester (very fine), Lord Wolseley, Golden Empress, Refulgence, Princess of Teck, Mrs. Heale, and Jardin des Plantes. Mr. Leadbetter was a good second, having very fine flowers of Lady Hardinge, Alfred Salter, and Princess of Wales. Only two collections were staged in this class. Four competitors entered the class for eighteen blooms, and Mr. J. Martin, gardener to Mrs. W. G. Bateson, was the successful exhibitor. This collection contained remarkably good blooms of Jeanne d'Arc, Queen of England, and Alfred Salter. Mr. A. R. Cox, gardener to W. H. Watts, Esq., Elm Hall, Wavertree, was a good second, the bloom of Lord Alcester and Princess Beatrice in this stand being especially fine. Mr. E. Broadeys, gardener to W. H. Jones, Esq., The Grange, Hooton, was placed third. For twelve blooms four collections were again staged, and the whole of the exhibits were praiseworthy. Mr. J. Wilson, gardener to J. E. Reynolds, Esq., Landsfield Park, West Derby, gained the premier position, and staged grand blooms of Lord Alcester, Empress of India and Golden Empress, both very large; Mrs. W. Shipman and John Salter were also very good. Messrs. T. Leadbetter and A. R. Cox were second and third respectively. In the corresponding class for twelve blooms the competition was keen, and several collections were staged for the three prizes offered. Mr. C. Osborne, gardener to W. S. Taylor, Esq., Ivy House, Allerton, took the lead, followed by Mr. F. Roberts with smaller but slightly fresher flowers. Mr. C. Gittins, gardener to W. W. Brocklebank,

Esq., Bromborough, third with rather flat blooms. The principal winner for six blooms was Mr. W. Riding, gardener to W. W. Sandbrook, Esq.

For twenty-four Japanese varieties, distinct, Mr. A. R. Cox was deservedly placed first with a magnificent collection of bright, fresh, large blooms. Mr. J. Martin was placed second and Mr. F. Roberts third with rather small but very fresh blooms. The premier collection comprised the following:—Belle Paule, Curiosity, Red Gannet, Peter the Great, Japonaise, Fair Maid of Guernsey, Madame C. Audiguier, Mons. Astorg, Balmoreau, Duchess of Albany, Daimio, Boule d'Or, Baron de Prailly, Criterion, F. A. Davies, Elaine, Comte de Germiny, Mons. Tarin, Chang, Mons. Burnet, Golden Dragon, Fernand Feral, and Meg Merrilees. Four collections were staged in this class. For eighteen blooms five competitors staged, and the whole were highly commendable, as the various collections scarcely contained a poor flower. Mr. J. Wilson took the lead and staged wonderful flowers of Criterion, Golden Dragon, F. A. Davies, Mons. J. Laing, Baron de Prailly, and Boule d'Or. Mr. J. Jellico was placed second, and had very fine Meg Merrilees and Triomphe de la Rue des Châlets, the remaining blooms being rather smaller than the first-prize collection. For twelve blooms three boxes only were staged, the prizetakers being in the order named—Mr. C. Osborne, Mr. E. Broadeys, and Mr. E. Curson, gardener to E. Meycock, Esq., Egerton Park, Rock Ferry.

The prizewinners for six reflexed blooms were Messrs. W. Wilson and J. Jellico, the former staging grand flowers of King of the Crimsons, Lilac and Golden Christine, Dr. Sharp, Mrs. Forsyth, and Chevalier Domage. Four collections were staged for the prizes offered for six Anemone-flowered varieties. Mr. W. Wilson was again first with fine examples of Bijou, Acquisition, Gluck, Lady Margaret, and Fleur de Marie; Mr. A. R. Cox second, and Mr. C. Watson, gardener to F. Tobin, Esq., Mersey Road, Aigburth, third. The remaining two small classes provided in the schedule were well filled but call for no special remark.

Chrysanthemums in Pots.—These were as numerous as usual, but the closely trained specimens that are generally a feature were not on the whole quite equal to the usual excellent condition in which these plants are shown. The classes provided for bushes or untrained specimens were certainly better than any we have seen in St. George's Hall before, but there is still room for great improvement. For six large-flowering trained plants, Mr. J. Hughes, gardener to H. McIver, Esq., Allerton, was well to the fore with good plants, well flowered, of Jardin des Plantes, George Glenney, Mrs. Shipman, Empress of India, Lady Hardinge, and John Salter. Mr. C. Finnigan, Palace Gardens, New Brighton, second with well-grown specimens, but considerably smaller blooms. Mr. W. Bustard, gardener to J. Lewis, Esq., Aigburth, was third, four collections being staged. For three plants Mr. T. Jones, gardener to W. C. Clarke, Esq., was first; Mr. J. Harrison, gardener to G. Pilkington, Esq., Woolton, second; and Mr. C. Finnigan third. For one plant Mr. J. Hughes took the lead, followed by Messrs. T. Jones and C. Finnigan. For six Pompons trained Mr. C. Finnigan took the lead with well-grown, profusely flowered plants of Lilac, White, and Golden Cedo Nulli, Mr. Astie, Mrs. Wheeler, and St. Michael. Mr. J. Hughes was placed second with rather smaller plants, which were remarkably fresh, but scarcely in full bloom, Mr. W. Bustard the remaining award. With three plants the successful competitors were Messrs. C. Finnigan, T. Blackmore, gardener to Major Pemberton, Fairfield, and J. Hughes, all staging creditable plants. Mr. Hughes took the lead with one plant, followed by Messrs. C. Finnigan and T. Blackmore. Eight exhibitors staged for the prizes offered in this class. Mr. E. Green, gardener to J. Woolright, Esq., Mossley Hill, was first in the class for one standard as well as in the corresponding class for one pyramid.

PLANTS.

Stove and Greenhouse Plants.—Mr. A. R. Cox won premier honours for six plants with good large plants of *Latania borbonica*, *Dicksonia antarctica*, and *Croton Queen Victoria* well coloured; *Ixora coccinea*, a good plant fairly well flowered; *Erica hyemalis*, 5 feet through, very fine; and a large plant of *Epacris* not named. Mr. J. Jellico was placed second with a grand well-flowered example of *Rhododendron Princess Royal*, *Cycas revoluta*, *Croton Hawkeri*, a good plant, but the whole of the foliage drooping, *Centropogon Lucyanus* fairly flowered, a good pot of *Calanthe Veitchii*, and a well-grown plant of *Latania borbonica*. Mr. A. Crosbie, gardener to B. Hall, Esq., Dudlow House, was awarded the remaining prize. For four plants the same competitor was again placed first, having a grand plant of *Cypripedium insigne* with over twenty flowers fully expanded, a large plant of *Ixora Dixiana* in good condition for this season of the year, and *Croton Disraeli* very good. Mr. R. Cubbon, gardener to Mrs. Alison Johnson, Woolton, was second, having good *Eucharis amazonica*, carrying nearly twenty spikes, and two good *Crotons Weismanni* and *C. interruptus*. Mr. A. Crosbie was placed third, having also a good *Eucharis* and *Cocos Weddelliana*.

Table Plants.—Good numbers of these were staged, and no less than twelve competitors arranged plants for the three prizes given for six plants. Those exhibited were of small size and in admirable condition, for there was not a faulty or an unsuitable plant amongst the exhibits. The plants were arranged down one of the central tables, nearly the whole length of the hall, in one row down the centre. Mr. J. Agnew, gardener to Mrs. Watts, was deservedly placed first with beautiful little plants of *Dracena gracilis*, *D. Sydneyi*, *Pandanus Veitchii*, *Cocos Weddelliana*, *Croton interruptus aureus*, and *C. Rodeckianus*. Mr. T. Fleetwood, gardener to T. H. Harrison, Esq., Holmfield, was a good second, and Mr. J. Hurst, gardener to W. B. Bowering, Esq., third.

Ferns.—The classes devoted to Ferns were well filled, and the plants staged by the various exhibitors were freely developed specimens. For four stove and greenhouse kinds Mr. R. Cubbon was deservedly placed first with grand plants, about 5 or 6 feet in diameter, of *Microlepia hirta cristata*, *Dicksonia antarctica*, *Davallia Mooreana*, and *Adiantum trapeziforme*. Mr. T. Gowan, gardener to J. Cunningham, Esq., was second with *Adiantum farleyense*, *A. Veitchii* very fine, *Gleichenia spelunca*, and *Gymnogramma argyrophyllum*. Mr. A. R. Cox was third, and his collection of plants was also very good. For one Tree Fern Mr. R. Cubbon was again first with a grand example of *Dicksonia antarctica*; second Mr. J. Lowndes, gardener to S. S. Parker, Esq., Aigburth, who staged the same variety.

Palms and Cycads.—Two classes only were provided for these plants, and in the class for three Mr. R. Cubbon was well to the front with *Cycas*

revoluta, *Arecalutescens*, and *Seaforthia elegans*, all being clean, well-grown, fair-sized specimens. Mr. J. Vaughan, gardener to R. C. Callart, Esq., The Hollies, Aigburth, was placed second, and Mr. C. Finnigan third. For one plant Mr. R. Cubbon was the only exhibitor, and was awarded the first prize offered.

Primulas.—There were not numerous, but were well grown and very creditable to the exhibitors. For six plants, Mr. T. Foster, gardener to J. Braucker, Esq., Wavertree, was first, while Mr. Agnew was placed second with larger but not such well-bloomed plants as those in the leading collection. Mr. E. Green was the remaining prizetaker.

Mignonette and Epiphyllums.—The first was not staged in large numbers but the exhibits were good. For one standard Mr. W. Wilson was placed first; second, Mr. J. Lewis; and third, Mr. J. Hurst. *Epiphyllums* were very good and well bloomed, but their appearance was destroyed by the manner of staking adopted. Some of the plants, which were standards, had nearly twenty stakes in them to support their heads. Nothing could have looked more unsightly than these down the centre of the fruit tables, for the whole of the stakes were seen.

Pelargoniums, Cyclamens, and Poinsettias.—Only one exhibitor staged in this class for six plants. The plants were well grown and profusely flowered, considering the season of the year. Mr. W. Wilson was awarded the first prize. Only one exhibitor staged in the class for *Cyclamens*, which need no further comment. *Poinsettias* were very good, and Mr. A. Crosbie took the lead for six plants possessing large well-developed heads, with foliage down to the base.

Orchids.—There was a slight falling off in the number of these plants exhibited, which no doubt is due to Mr. W. Mease retiring from the field as an exhibitor and the dispersion of the collection belonging to the late T. S. Walker, Esq. The prizes offered, however, were well contested, but the exhibits were not so numerous as previously. For three plants Mr. T. North, gardener to E. Harvey, Esq., Aigburth, took the lead with a fine example of *Odontoglossum Rossi majus* with twenty or more flowers, a large pan of *Cypripedium Spicerianum*, and *Odontoglossum grande* with three fine spikes. Mr. W. Moss, gardener to W. Holland, Esq., Aigburth, was a good second with *Odontoglossum Alexandrae* with three spikes, *Burlingtonia fragrans*, and *Cymbidium Mastersiana*. Mr. E. Green was a very good third. For one plant Mr. T. Worth was again first with *Laelia elegans picta*; Mr. Moss followed with *Cypripedium Sedeni* with about ten spikes, and Mr. A. R. Cox third with *Oncidium varicosum*. Seven or eight competitors staged for the prizes offered in this class. For one *Cypripedium* Mr. Moss was placed first with a large pan of *C. insigne* with about thirty flowers, Mr. A. R. Cox, second with a good plant of the same variety, and Mr. C. Cople, gardener to Stanley Rogerson, Esq., St. Michael's Hamlet, third. For two *Calanthes* Mr. W. Moss was first, and the same exhibitor was also successful for one plant.

Bouquets.—Those shown were on the whole light, shapely, and composed of very choice flowers. For one (open class) Miss M. A. Cooke, Southport, was first, and Mr. G. Downes, Lodge Lane, second. In the corresponding class for one Mr. A. Crosbie was followed by Mr. Watts, and Mr. J. Fairhurst, gardener to P. H. Blessig, Esq., Allerton. For one epergne or vase Mr. J. Lewis was first and Mr. C. Cople second.

FRUIT.

On the whole the display of fruit was not only more numerous than on previous occasions, but the quality throughout was superior. The exhibition of fruit alone was considered by those capable of judging to have been the finest show of fruit that has been brought together this autumn. For twelve distinct dishes Mr. J. H. Goodacre, gardener to the Earl of Harrington, Elvaston Castle, Derby, gained the premier position with fair Muscat of Alexandria Grapes, Alicante, Gros Colman, good in bunch, berry, and colour, and a very fine example of Mrs. Pearson Grape, a small Hero of Lockinge Melon. Pears Beurré Clairgeau, Marie Louise, and Duchesse d'Angoulême were large. Apples King of the Pippins, Winter Pearmain, and Queen Charlotte were also large and well coloured. Mr. J. Bennett, gardener to Hon. C. H. Wynne, North Wales, was second with good Alicante and Gros Colman Grapes. The bunches staged of Foster's Seedling and Syrian were small in the berry; Cox's Pomona Apple and Urbaniste Pears were very good. Mr. W. Hannagan, gardener to R. C. Naylor, Esq., Hooton Hall, Cheshire, was third, and staged good Alicante and Gros Colman Grapes. For six dishes Mr. Goodacre was again first with very fine examples of Muscat of Alexandria and Gros Colman Grapes, the latter being well coloured with very large berries, Beurré Diel and Marie Louise Pears, a fine dish of Blenheim Pippin Apples, and a small Melon. Mr. Hannagan was a close second, and staged remarkably fine fruits of Marie Louise and Doyenné du Comice Pears. Mr. J. Hurst gained the remaining prize. Eight collections were staged in this class.

Grapes.—For two bunches of black Grapes (Muscat flavoured) five exhibitors competed for the prizes. Mr. J. Hollingsworth, gardener to F. Campbell, Esq., Woodseat, gained the premier position with good bunches of Mrs. Pince, perfect in colour and large in both bunch and berry. Mr. J. Barker, gardener to Alderman Raynes, Rock Ferry, was placed second with Madresfield Court, perfect in colour and size of berry, but the bunches were rather small. Mr. Goodacre secured the remaining award with bunches a little less, but in other respects equally good. In the corresponding class for two bunches (without Muscat flavour) no less than sixteen exhibitors staged, and there was not a faulty exhibit in the whole. Mr. A. Collins, gardener to Samuel Smith, Esq., Prince's Park, gained the premier award with very large well-coloured bunches of Gros Guillaume. Mr. J. Hollingsworth was placed second with smaller but perfectly shaped well-coloured examples of the same variety; Mr. Goodacre third with Gros Colman, the two finest bunches of this variety in the Exhibition, the bunches being large, the colour good, and the berries of great size. Mr. T. Bradshaw, gardener to W. Watson, Esq., Spital, was awarded an extra prize for two large perfectly finished bunches of Alicante. For two bunches of Black Hamburgs there were only three competitors, but the fruit was in good condition, considering the season of the year, for this variety. Messrs. Goodacre, J. Barker, and T. Fleetwood were the prizetakers.

For two bunches of Muscat of Alexandria Mr. G. Middleton, gardener to R. Pilkington, Esq., Rainford Hall, was well ahead with the two finest bunches of this variety in the Show, the bunches in question being large

in size with large even berries perfectly coloured. Mr. J. Bounds, gardener to A. L. Jones, Esq., Aigburth, and Mr. T. Elsworthy, gardener to A. R. Gladstone, Esq., Court Hey, were placed second and third in the order named. There were six exhibitors of two bunches of any other variety of white Grapes. Mr. J. Hollingsworth was first with clean large bunches of Golden Queen. Mr. J. Wallis, gardener to Rev. W. Sneyd, Keele Hall, Staffordsbri e, was second with the same variety, and Mr. Goodacre third, also showing the same kind. All the competitors in this class staged Golden Queen, and the majority were of a dirty colour. For four bunches Mr. Hollingsworth took the lead with grand bunches of Mrs. Pince, Trebbiano, Alicante, and Golden Queen; Mr. T. Elsworthy being placed second with Golden Queen, Alicante, Alnwick Seedling very fine, and Muscat of Alexandria, Mr. Goodacre being third. Thirty-two bunches were staged for the prizes offered. Mr. J. Bennett was the only exhibitor in the two classes for Pines, and staged some large good fruits, for which he was awarded the two first prizes.

Pears.—These were not only numerous but the exhibits throughout were of the finest quality, being both large in size and well coloured. For eight dishes of dessert kinds, distinct, Rev. L. Garnett, Christleton Rectory, Chester, was well to the front with remarkable examples of Gansel's Bergamot, Pitmaston Duchess very fine, Doyenné du Comice very large, Beurré Bosc, General Todtleben, Brown Beurré, Maréchal de Cour, and Marie Louise. Mr. Goodacre was a capital second, who staged Catshead Bergamot, Pitmaston Duchesse Duchesse d'Angoulême, and other kinds as named above. Mr. Hannagan was third, and in addition to those named above this collection contained a very fine dish of Hacon's Incomparable. No less than fifty-six dishes of fruit were staged in this class. For four dishes the competition was equally good, and as many exhibitors staged collections. Mr. T. Weeden, gardener to T. Case Morris, Esq., Beechwood, Aigburth, gained the premier position with grand dishes of Beurré Diel, Pitmaston Duchesse extra large, Glou Morceau, and Doyenné du Comice. Mr. J. Lowndes was second, and Mr. Hannagan third, both showing remarkably well. For one dish the Rev. L. Garnett was placed first with a splendid dish of Doyenné du Comice; second, Mr. N. E. Owen, gardener to Viscount Combermere, Salop, with Marie Louise; and Mr. J. Davies, gardener to Rev. R. Arkwright third. Twelve dishes were staged. About the same quantity was staged for one dish of stewing kinds. Mr. T. Weeden was well first with Pitmaston Duchess, probably three times larger than any other fruit of this variety in the Exhibition. The fruits were wonderfully fine, and said to have been grown on a small plant in a pot. Mr. J. Davies second with Catillac, and Mr. Hannagan third with the same variety.

Apples.—These were large and much better coloured than we have previously seen exhibited at this Society's exhibition. Eight collections were staged in the class for six dishes of dessert kinds. Mr. F. Miller, gardener to J. F. Friend, Esq., Moorgate, was well first with superbly coloured large fruit of Pearn's Pippin, Scarlet Pearmain, King of the Pippins, Ribston Pippin, Cornish Aromatic, and Blenheim Pippin. Mr. Goodacre was a good second, and staged very fine dishes of Blenheim Nonesuch, King of the Pippins, Winter Pearmain, Cox's Orange Pippin, and Adam's Pearmain. Mr. J. Davies was placed third with similar varieties. For three dishes the successful exhibitors were Mr. A. Eaton, gardener to H. Robinson, Esq.; Mr. R. Brownhill, gardener to R. Hargraves, Esq., Ravenswood, Rock Ferry; and Mr. J. Lowndes. Eight collections were staged in this class. In the class for one dish nine exhibitors staged. Rev. L. Garnett took the lead with Cox's Orange Pippin, Messrs. E. Owen and J. Barker second and third. For eight dishes of kitchen varieties seventy-two dishes were staged. Mr. F. Miller was well first with Mère de Ménage, Waltham Abbey Seedling, Annie Elizabeth, Alexandra, Blenheim Pippin, Peasgood's Nonesuch, and Small's Admirable; all were large and well-coloured examples. Mr. Goodacre was a close second and Mr. W. Edwards, Thinghill, Hereford, third. For four dishes eight collections were staged, the successful competitors being Messrs. L. D. Turner, T. Weeden, and J. Kelly, gardener to R. Singlehurst, Esq., Aigburth. For one dish Mr. Edwards, Hereford, was well first, Mr. F. Miller second, and Mr. J. Davies third.

Vegetables were not very largely shown, as only two classes were provided for them. For a collection of six varieties Mr. Goodacre took the lead with grand samples, followed by Mr. Hannagan and Mr. N. E. Owen. The same exhibitor was again first for one dish of Tomatoes, Dedbam Favourite; Mr. J. Smeatham, gardener to F. D. Nuttall, Esq., St. Helens, second, and Mr. J. Bounds third.

Miscellaneous Exhibits.—These added materially to the beauty of the Exhibition. Messrs. R. P. Ker & Sons, Aigburth, contributed a beautiful bank of Cyclamens, which were very effective and much admired, for which a first-class certificate was awarded. A similar award was made to the Liverpool Horticultural Company (John Cowan) for an assortment of small decorative flowering and foliage plants. Certificates of merit were also awarded to Messrs. James Dickson & Sons, Newton Nurseries, Chester, for a collection of eighty varieties of Apples and about thirty varieties of Pears; Messrs. R. Smith & Co., Worcester; Messrs. F. & A. Dickson and Sons, The Upton Nursery, Chester; and Mr. C. Ryland, Aughton, Ormskirk. The collections from all were large and very praiseworthy. Messrs. Blake and Mackenzie exhibited a quantity of their plant and cut flower boxes. Mr. E. Sydney contributed a large quantity of vases and other similar articles made of slag ware. Mr. J. P. Bethell exhibited a large quantity of their unique folding flower boxes.

The arrangements of this very fine Exhibition were of a very complete and satisfactory character, and the highest credit is due to Mr. Bridge, the able Secretary, as well as the whole of the working Committee.

ROYAL CALEDONIAN HORTICULTURAL SOCIETY'S

WINTER SHOW.—NOVEMBER 25TH AND 26TH.

It was a happy thought to get up an Apple and Pear Congress in connection with the Winter Show this year, for had it not been for these fruits the Show must have been a failure. There were hardly any pot plants of merit; the Chrysanthemums in pots were of indifferent quality, and though there were some blooms of these of good size shown the competition was of the poorest description. Vegetables and hardy fruits were the only articles which brought out any competition.

For a table of plants, Chrysanthemums and others, 40 feet by 10 feet, Messrs. Ireland and Thomson took first prize, the centre of the group being a bold and effective mass of naturally grown Chrysanthemums with a broad edging of stove and greenhouse plants round the central group. Messrs. Methven and Sons were second. For a table of the same kind of plants confined to gardeners, and 20 feet by 5 feet, Mr. Grossart, gardener to Mr. Buchanan, Oswald Road, was first, and Mr. Smith, Restalrig, second. Stove and greenhouse plants were very poor, though Mr. Scott, gardener to Lord Elphinstone, Carberry Tower, showed six good foliage plants. Mr. Niel Fraser, Murrayfield, in the class for six exotic Ferns, had good specimens of *Gymnogramma javanica*, a distinct species, with little in its general appearance to suggest the family to which it belongs. A very fine *Goniophlebium appendiculatum*, a *Davallia dissecta*, and *Todea intermedia* were the best of the other kinds. Some good *Adiantums* in variety were also shown. Mr. Grossart was the only exhibitor of two Orchids, getting for these first prize, and staging a fine plant of *Lælia autumnalis atro-rubens* with five strong spikes, and *Vanda carulea* with one spike. A large number of prizes were offered for Chrysanthemums in pots, but the plants staged were of the poorest description. Some of the nurserymen sent fine groups of *Coniferae* and hardy shrubs suitable for winter decoration, and for these Messrs. Ireland and Thomson took first prize with fine plants, Messrs. Methven and Sons being second with an equally effective but plants of a smaller size. The rest of the prizes for plants brought out a poor competition.

Of the Chrysanthemum blooms, the best were those which follow:—Twenty incurred (nurserymen), first to Mr. T. B. Morton, Mowden Bridge Nursery, Darlington, his best blooms being Lord Alcester, Alfred Salter, John Salter, Princess of Wales, Beauty, and Prince Alfred. Second Messrs. Ireland and Thomson. Twenty Japanese—First Messrs. Ireland & Thomson, who had among others very fine examples of Elaine, Criterion, Fair Maid of Guernsey, Comte de Germiny, Mad. C. Audiguier, F. A. Davis, La Nympe, Mad. A. Roze, Curiosity, and Henri Jacotot. Mr. Morton was a close second. For ten incurred, ten Japanese, and ten reflexed Mr. Morton was first—of the latter Cullingfordi was very fine—also first for ten Anemones, among which the Japanese varieties, Sœur Dorothee Souille, Fabian de Mediana, and Marquise de Telleville were good.

In the gardeners' classes Mr. Forbes, gardener to J. S. Morgan, Esq., Dover House, Roehampton, was first with good, though rather aged blooms; Mr. Carruthers, Corstophine, second, with much looser blooms. For twelve Japanese Mr. Carruthers was first, his blooms having the colours blanched through forcing, Mr. Forbes being second with much finer blooms. Mr. Forbes was also first for twelve incurred and ten Japanese, and for six Anemone and six reflexed, and for six sent out since 1882, with F. A. Davies, Jeanne d'Arc, Mr. J. Laing, Lord Wolseley, Lord Alcester, and Duchess of Albany. Some pretty bouquets were shown, and Messrs. Todd & Co., and Messrs. Methven & Sons, showed beautiful examples of wreaths, &c.

There were only two collections of six sorts fruit staged, Mr. McIndoe, Hutton Hall, Gnisborough, being first with a Pine Apple, Trebbiano, and Barbarossa Grapes, very fine Beurré Diel Pears, Blenheim Pippin Apples, and Oranges. Mr. McIntyre, The Glen, Innerleithen, had the other collection. Mr. Hunter, Lambton Gardens, Durham, and Mr. McIndoe were the fortunate exhibitors of Pine Apples. For eight bunches Grapes four exhibitors staged, Mr. Murray, Park Hall, Falkirk, being easily first with extra large and fine bunches of Gros Colman, Mrs. Pince, Syrian, Gros Guillaume, Lady Downe's, and fine Golden Queen. Mr. McHattie, gardener to the Marquis of Lothian, Newbattle Abbey, Dalkeith, second. In the class of four bunches Mr. Murray was again first with Lady Downe's, Gros Colman, Mrs. Pince, and Alicante, all fine. Mr. D. Howie, gardener to Rev. Mr. Bruce, Donimale, second with equally good though small bunches. Mr. Murray, with two extra good Black Hamburgs, was first in that class, Mr. Mattheson, gardener to W. Tod, Esq., Glenesk, Musselburgh, second. Mr. McKelvie, gardener to the Duchess of Roxburgh, Broxmouth, Dunbar, was first for two bunches of Muscat of Alexandria, very fine; and Mr. Johnston, gardener to Earl of Strathmore, Glamis, second, also with good fruits. For one bunch of same Grape Mr. G. Greig, gardener, Craigend Park, was first. Mr. Borthwick, gardener to Sir G. Montgomery, Stobo Castle, Peebles, first for one bunch Black Hamburg rather shrivelled. For one bunch of Alicante Mr. Niell, gardener to F. Allen, Esq., Peelwallis, Ayton, was first with a very fine example. For one bunch Gros Colman Mr. Murray, gardener to T. L. Learmonth, Esq., Parkhall, Falkirk, was first with a remarkably fine example. From Mr. Murray, gardener to Marquis of Ailsa, came the finest Alnwick Seedling. Mr. Brunton, gardener to Sir A. Kinloch, Bart., Gilmerton, Drem, had the best flavoured black, Muscat Hamburg; Mr. McIndoe the best flavoured white, Muscat of Alexandria. Mr. Niell, Ayton, had the finest bloomed bunch, Alicante. The best bunch of any other black Grape than those named in schedule was an extra fine example of Mrs. Pince from Mr. Jeffrey, gardener to A. Pringle, Esq., Craigcleuch, Langholm.

Pears, though not numerous, were generally of fine quality, most of them being evidently the produce of trees grown in glass structures. For a collection of twenty or more sorts Mr. Hunter, gardener to the Earl of Durham Lambton Gardens, was first with among other grand examples of Beurre Diel, Napoleon, Duchesse d'Angoulême, Pitmaston Duchess, General Todtleben, Marie Louise, Drondeau, Dr. Delafosse, and Marie Benoist. Mr. McIndoe second with a much larger number of sorts, but the fruits much smaller. The same exhibitors were first and second respectively for twelve sorts of Pears; Mr. Murray, Parkhall, first for six sorts; and for two sorts Mr. McIndoe first and Mr. Black, Smeaton Gardens, Preston Kirk, second with fine fruit from wall cordons.

The prizes for Apples were very keenly contested, examples from orchard houses, wall trees, espaliers, cordons, and bushes being presented. For a collection of thirty or more varieties, Mr. McKenzie, gardener to F. S. W. Cornwallis, Esq., Linton Park, Maidstone, was first, showing among other fine examples of stove Apples, Peasgood's Nonsuch, Mère de Ménage, Alexander, Gloria Mundi, Cobbet's Pearmain, and Waltham Abbey Seedling. Mr. Galloway, gardener to the Earl Minto, Minto, Hawick, second with a very even lot, grown on wall trees, and extra well finished for Scotch Apples, Ravelston Pippin, Striped Beaufin, Ribston, Blenheim, King of Pippins, and Adams' Pearmain were the best. For twelve sorts Mr. McIndoe was first, his best being Gasgoigne's Seedling, Mère de Ménage, and Waltham Abbey Seedling. Mr. Potter, Seacliff, North Berwick, second. For six sorts Mr. Brunton was first. Among other single dishes the following were good—

viz., Blenheim Orange, Mr. McIntyre, gardener to Mrs. Pease, Woodside, Darlington, being first; Stirling Castle, first Mr. Lamont, Kennet House; Golden Noble, first Mr. D. Logan, Coldstream; Lord Suffield, first Mr. Potter; Warner's King, first Mr. McKelvie, who also had first for King of the Pippins. The heaviest Apples being Gloria Mundi from Mr. McKenzie, Linton Park.

Vegetables were a very good show. For twelve varieties (market gardeners) Mr. Logan, Coldstream, was first with a fair lot. Mr. Potter, Seacliff, being first in the gardeners' class with good Celery, Tomatoes, fine Brussels Sprouts, and Veitch's Protecting Autumn Broccoli. For twelve Tomatoes Mr. Gordon, Niddrie House, was first. Mr. Potter had extra fine Brussels Sprouts; Cauliflowers, Onions, and Leeks were very fine. Mr. Cockburn, Stenton, East Lothian, showed a very fine dwarf strain of Parsley, and Mr. Donaldson, Keith Hall, had the best Potatoes.

Among miscellaneous exhibits was a basket of rare and beautiful flowers from Dr. Paterson, Bridge of Allan; basket of Grapes from Mr. Thomson, Clovenfords; examples of variously trained Apple trees from Messrs. Dickson & Co.; and a table of fine plants from Messrs. Laird & Sons, Pinkhill.

APPLE AND PEAR "CONGRESS."

The Apple and Pear "Congress," as already stated, saved the Show from being a failure. The whole of the northern half of the Waverley Market, and the west end of that building was set apart for these fruits. Four tables, each over a hundred yards in length, besides several smaller tables, were filled entirely with the fruit sent for the Congress. About 12,000 dishes of fruit were staged, and all parts of the United Kingdom and Ireland were represented in addition to a few dishes from Switzerland and a good collection from Nova Scotia. The British Apples came from such diverse quarters as the Orkney Islands, the Isle of Mull, Caithness, &c., in the north of Scotland, and Surrey and Kent in the south of England. Taking the Scotch Apples first, the county which staged the largest number of dishes was the home one, Midlothian, 1350 being set up by seventeen exhibitors, several of whom were nurserymen. Roxburghshire came next with 750 dishes, East Lothian with 660, and Lanark with 510. As a whole the finest fruit came from East Lothian, Roxburghshire, and Berwickshire, though there were individual cases in other counties, even the far north, where good fruit was to be found. Judging from the fruit staged the number of sorts which are relied on are not numerous, a few well-known sorts being found in most of the collections. One of the most common is the Old Catshead; Warner's King, Keswick Codlin, and Lord Suffield are also very common sorts, and in most districts these grow to a good size. In fact Catshead from Orkney was quite as large as it is to be found in the south of Scotland, though of course very green.

Aberdeen.—There were twelve exhibitors from this county and about 340 dishes were staged some of the fruit was very good, while others was extremely green, hard, and small. Messrs. Cocker & Sons, Aberdeen, staged eighty-four sorts Apples, Tower of Glamis, Stirling Castle, Worcester Pearmain, and Wellington being very good. Mr. Donaldson, gardener to Earl of Kintore, Inverury, had sixty-three dishes Apples and nine of Pears, the latter small and green, the Apples good, Warner's King, Red Astrachan, and Kentish Fillbasket very good. Mr. Harris, Kincardine, O'Neil, in his twenty-four sorts had good Dutch Codlin, Cellini, Golden Spire, and Fulwood, in addition to sorts already named. Other exhibitors were Mr. Forrest, Haddo House, Messrs. W. Smith & Sons (150 dishes), Mr. Harper, Monalten Gardens, Mr. P. Glennie, Bielack, Mr. R. Pirie, Castle Newe, Mr. Farquhar, Fyvie Castle, Mr. Smith Duncacht, Mr. J. Hardy, Aboyne, Mr. Stephen, Crathes Castle, and Mr. Kilgour, Edge Hill.

Ayrshire.—Five exhibitors, 266 dishes. Mr. A. Bogie, Auchans House, 170 sorts though small well coloured, some good examples from wall or from pot culture; Mr. Gilchrist, Hurlford, thirty dishes well coloured; Mr. Wilson, Auchincrim, Ayr, forty-two dishes, including a fine dish of Duchesse d'Angoulême Pears; Mr. Gallacher, Kilkerran, Maybole, nine dishes of very good fruit, Pott's Seedling and Ecklinville, fine; Mr. McKinnon, Dumfries House, fifteen dishes.

Argyleshire.—Mr. Grierson, Torleisk Gardens, Tobermory, Isle of Mull, had seventeen dishes, Alexander, Lord Suffield, and Cox's Pomona from a south wall being very fine indeed, and Thorle Pippin and Dumelow's Seedling from standard, good.

Berwickshire.—Eight exhibits came from this county, some very good fruit being staged. Mr. Fowler, Mertoun House, St. Boswells, showed fifty-six sorts of Apples and eighteen of Pears; of the latter Beurré Diel, Marie Louise, and St. Lawrence were fine, Peasgood's Nonsuch, Paradise Pippin, Worcester Pearmain, and Lord Suffield among the Apples very fine. Mr. McIntosh, Paxton House, Berwick, staged 110 dishes, not of a large size of fruit but well coloured. Mr. Cairns of The Hirsell; Mr. Renton, Lees; and Mr. Hogg, Hope Park, Coldstream, each staged very large collections of fine fruit. The latter had very fine Conseiller de la Cour and Beurré Clairgeau Pears; and among the Apples in these collections were White Melrose, Cox's Pomona, Court Pendu Plat, and Manx Codlin. Mr. Robertson, Cowden Knowes, Earlston, forty dishes of rather small fruits.

Banffshire.—Mr. Berry, Cullen House, Cullen, staged 100 dishes, eighteen of which were Pears; the Apples were small though well coloured.

Caithnesshire.—Mr. D. Munro, Keiss Castle, Wick, showed thirty sorts mostly small, Catshead large.

Clackmannan.—Mr. J. Lamont, Kennet House, had fifty sorts of good size though wanting in colour.

Dumbartonshire.—Mr. Mitchell, Camis Eskan, had thirty dishes, mostly small and very green.

Dumfriesshire.—Messrs. Thomas Kennedy & Co., Dumfries, 100 dishes of very good fruits, Gloria Mundi, Mère de Ménage, Golden Spire, Lord Derby, Catshead, Hollandbury, and Tower of Glamis the best. Mr. J. Hamilton, Dorncliff, Moffat, twenty dishes of very small fruits.

East Lothian.—Eight exhibitors. Most of the fruit shown was of a good size, and some of it well coloured. Mr. Black, gardener, Smeaton House, Prestonkirk, showed sixty-three dishes, Newtown Pippin and Irish Peach fine. Mr. Brotherston, Earl of Haddington, Tynninghame, had eighty-four dishes, Warner's King, Ecklinville, Mère de Ménage, Cox's Pomona, being good. Mr. Brunton, gardener to Sir A. Kinloch, Bart., Gilmerton, Drem, had twenty-two dishes Pears and 110 Apples, fruit fine. Stone's Apple Old

English Codlin, and Cellini firm. Mr. Dow, gardener to Sir D. Baird, Newbyth, had sixteen dishes Pears, sixty-one Apples; the Pears very fine, especially Moorfowl Egg, Beurré Diel, Beurré d'Amanlis, and Hacon's Incomparable. Mr. Garrett, gardener to J. B. Balfour, Esq., Whittinghame, showed eighty dishes of Apples, the fruit of good size, but wanting in colour, Golden Noble fine. Mr. G. Potter, Seacliff, North Berwick, had sixty-seven dishes, good colour, fine fruit. Mr. Morrison, gardener to Miss Hamilton, Archerfield, Drem, had thirty dishes Pears and 110 Apples. These were generally small. Mr. McKelvie, Broxmouth, Dunbar, contributed thirty-six sorts, good highly coloured. First Warner's King and Greenup's Pippin especially fine.

Fife.—Five collections, 240 dishes, five exhibitors, fruit generally good size and well coloured. Mr. Grant, Cambo House, Crail, had sixty-two dishes. Mr. Henderson, Balbirnie, Markinch, showed sixty-four of rather smallish fruits. Mr. Williamson, gardener to J. H. Riggs, Esq., Tarvet House, Cupar, had seventy-two dishes, very good. Mr. Tait, gardener to Sir T. Coutts Lindsay, Bart., Balcarres, fifty dishes of good well-coloured fruits.

Forfar.—Three exhibitors, 410 dishes. Messrs. Laird and Sinclair had 350 dishes, some of which were very good. Mr. D. D. Anderson, Green-bourne, Monifieth, contributed eighty dishes, and Mr. Johnston, Glamis Castle, Glamis, eighty dishes of small and green fruits.

Lanarkshire.—510 dishes, ten exhibitors. Mr. Gorrie, gardener to W. H. Hoyer, Esq., Mauldslee, Carluke, had 285 dishes small but highly coloured fruits. Mr. King, Dalzell Gardens, Motherwell, had fifty dishes, also small and some well coloured, the others were generally poor and wanting in colour.

Midlothian.—Seventeen exhibitors, 1350 dishes. Mr. Dunn, gardener to Duke of Buccleuch, Dalkeith, staged seventy dishes of Pears and 260 of Apples, the fruit being generally of a small size and rather greenish. Sixty dishes were from dwarf bush, two years planted, the other four old standards, the latter much the best fruit. Yorkshire Beauty, Lord Suffield, and Alfriston were most noticeable in this collection, to which we may have an opportunity to refer again. The fruit in most of the other collections was also small in size and wanting in colour. Mr. Smith, gardener to Earl of Stair, Oxenford, and Mr. Gray, gardener to Sir J. Don Wauchope, Bart., Edmonston, having some good fruit in their collections. Messrs. Dickson and Co., Waterloo Place, staged 150 dishes from the Silverton Nurseries, some good examples being among these, Greenup's Pippin, Lord Suffield, Warner's King, Ecklinville (five seedlings) being among the best.

Morayshire.—Messrs. R. & A. Morrison, Elgin, staged a good collection of highly coloured fruit, Peasgood's Nonsuch being very fine; and Mr. Chrystal, gardener to Sir W. Gordon-Cumming, Bart., Altyre, Forres, had fifty dishes of fairly good fruits.

Nairnshire.—Two collections came from this northern county, but the fruit was rather small.

Orkney.—Mr. J. McDonald, gardener, Balfour Castle, sent twenty-one dishes, which were mostly small and very green.

Peeblesshire.—From the hilly county three exhibitors forwarded small collections, the best being from Sir C. Tennant, Bart., The Glen, Innerleithen. Those from Mr. Borthwick, Stobo Castle, Peebles, and from Mr. McFarlane, King's Meadow, were smaller and very green. Stirling Castle was fine from the last-named exhibitor.

Perthshire.—There were ten exhibitors from this county, who sent about 440 dishes. Much of the fruit was very small and greenish, but good examples were present in some of the collections. Mr. Robertson, Fern Bank House, Errol, staged 100 dishes, some of which were very good. Mr. Browning, The Gardens, Dupplin, Perth, had fifty dishes, very good, Lord Suffield being fine. Mr. Brown, Abercainey, had thirty dishes, and Mr. W. Bisset, gardener to Sir R. Moncrieff, Bart., Bridge of Earn, fifty dishes.

Renfrew.—Mr. Maxwell, gardener to Mrs. Clarke, Ralston House, sent thirty dishes, but the fruit was small and green.

Roxburghshire.—Seven hundred and fifty dishes came from this county, sent by seven exhibitors. Some of the fruit was very good. The best came from Mr. Dalrymple-Elliston, St. Boswells, the fruit evidently having been the produce of orchard house culture. There were forty-seven dishes of Pears and thirty-three of Apples in this collection. Of the former Uvedale's St. Germain, Bergamotte Esperen, Beurré d'Anjou, Passe Colmar, Beurré Diel, Doyenné du Comice, Nouvelle Fulvie, and Glou Morcean were especially fine; and of the latter Warner's King, Alfriston, Reinette du Canada, Rossignol, and Peasgood's Nonsuch. Mr. Kerr, Sunlaws, Kelso, showed forty-three dishes, many of which were good. The best were Catshead, Alfriston, Mère de Ménage, Dumelow's Seedling, Gravenstein, and Worcester Pearmain. Messrs. Stuart & Mein, Kelso, showed 210 dishes, a good and representative collection, mostly grown on nursery trees. Messrs. Laing and Mather, Kelso, had 150 sorts of Apples and eighteen Pears, which had been sent from local gardeners through them. There was much fairly good fruit, Golden Noble, Gravenstein, Maltster, Manx Codlin, Ecklinville, and Warner's King being most noticed. Messrs. Ormiston & Renwick, Melrose, sent 200 dishes very good, examples of White Melrose, Manx Codlin, The Queen, and Cox's Pomona being noticeable. Mr. Thomson, Eildon Hall, sent twenty-four dishes of good fruit.

Ross-shire.—Mr. Munro, gardener to A. Matheson, Esq., Duncraig, Stornoway, had 100 dishes, thirty of which were Pears of poor quality, and the Apples very green. Mr. Simpson, gardener to K. S. Mackenzie, Esq., Brahan Castle, Conon Bridge, fourteen Pears and sixteen Apples, not large, but many well coloured.

Stirlingshire.—Four hundred and two dishes came from this county sent by four exhibitors. Messrs. Drummond & Sons, Stirling, sent 186 dishes, seventy-eight of which were Pears. The fruit was mostly green, but some of good size, the best sorts being Warner's King, Catshead, Stirling Castle, Blenheim Pippin, Lord Suffield, and Yorkshire Greening. Mr. Souza, Touch, sent 110 dishes, eighteen of which were Pears, all small and mostly green. Mr. Carnegie, Leckie House, Stirling, sent twenty-three dishes of Apples and nine dishes of good Pears. The others were very poor.

Selkirkshire.—Mr. Anderson, Broadmeadows, forty dishes of fairly good Apples; Catshead, Stirling Castle, and Lord Suffield the best.

Sutherlandshire.—Mr. Melville, Dunrobin Castle, sent twenty dishes, and Mr. Urquhart, Skibo Castle, Dornoch, thirty dishes, very small and green; Catshead large.

Wigtonshire.—Mr. P. Lemon, gardener to J. F. Hathorn, Esq., Castle Wigg, Whithorn, had thirty-one dishes of green and small fruit.

ENGLAND.—The English Apples were largely shown on the tables, a large number of these being undistinguishable from the average Scotch as to size and quality. This of course refers to those from the north of England, as the large collection from Little & Ballantyne, Carlisle, and others. Kent sent the finest collection in the Show, that of Messrs. G. Bunyard & Sons, Maidstone; while the best from gardens was that of Mr. Smith, gardener to the Earl of Rosebery, Mentmore, Bucks. As with the Scotch counties, we shall take these in their alphabetical order.

Buckinghamshire.—As above noted, Mr. Smith forwarded the finest collection shown by gardeners, and consisted of 180 dishes of Apples, several of which were duplicates. The fruit was of good size and well coloured, the more remarkable being Blenheim Pippin, Bess Pool, Ecklinville, Warner's King, Gloria Mundi, Waltham Abbey Seedling, Cox's Pomona, Hanwell Souring, Alfriston, Golden Spire, Peasgood's Nonsuch, and Lady Henniker. Mr. G. T. Miles, gardener to Lord Carrington, Wycombe Abbey, sent twenty-six dishes Pears and thirty-four of Apples. Of the former, Beurré Diel and Glou Morceau were good, and of the latter, Dumelow's Seedling, Warner's King, Golden Noble, and Mère de Ménage.

Cumberland.—Messrs. Little & Ballantyne, Carlisle, set up 560 dishes, mainly from the gardens of this county. Much of the fruit was small and green, though much of it, on the other hand, was good. Lord Suffield, Brabant Bellefleur, Melon, Warner's King, Gloria Mundi, and Bank Apple were among the best sorts.

Durham.—Mr. Hunter, gardener to Earl of Durham, Lambton, sent fifty dishes of very green fruit, though generally of good size, Lord Suffield and Lord Derby the best.

Herefordshire.—From Mr. Watkins, Pomona Farm, Withington, came 210 dishes and eighty of the cider kinds, which attracted much attention from their beautiful colouring. The other sorts were also very highly coloured. Tom Putt, Mère de Ménage, Calville Rouge, Royal Codlin, Greaves' Pippin, Yorkshire Beauty, and Flanders Pippin were the most noticeable in this lot.

Kent.—Messrs. G. Bunyard & Son, Maidstone, showed 300 dishes, the finest samples being Cox's Orange, Gascoigne's Seedling, Dutch Mignonne, Lady Henniker, Cox's Pomona, New Hawthornden, Melon, Wellington, Warner's King, Peasgood's Nonsuch, Lord Derby, Mère de Ménage, Annie Elizabeth, Bleuheim Pippin, Hoary Morning, Gloria Mundi, Alexander, Worcester Pearmain, Reinette Van Mons, Nanny, Cornish Aromatic, Stirling Castle, Golden Noble, Duchess of Gloucester, &c., very fine. Pears—Beurré Rance, Beurré Diel, Doyenné de Comice, Durondeau, Marie Benoist, &c. Mr. McLean, gardener to Jas. Whatman, Esq., Vinters Park, Maidstone, had forty dishes, of which the best were Stone Pippin, Blenheim Pippin, Warner's King, &c. Mr. R. Young, 52, High Street, Sittingbourne, thirty dishes of fairly good Apples and a few Pears. Mr. Killick, Langley, a few dishes of fine fruit, including Stevens' Seedling, Tower of Glamis, King of the Pippins, and Blenheim Pippin.

Rutland.—Mr. Ingram, Belvoir Gardens, showed thirty-seven dishes of Pears, of which the following were fine:—Beurré d'Anjou, Beurré Clairgeau, General Todtleben, Pitmaston Duchess, and Hayshe's Bergamot; and fifty-eight dishes of Apples, of which Lord Lennox, Flower of Kent, Cox's Pomona, Peasgood's Nonsuch, Golden Noble, Lord Derby, Warner's King, and Blenheim Pippin were very fine.

Leicester.—Messrs. Harrison & Sons, Leicester, sent a good collection, Lord Melbourne being the most noticeable kind.

Middlesex.—Messrs. Veitch & Sons, Fulham Nurseries, London, sent a fine collection consisting of 145 sorts of Apples and seventy-four sorts of Pears. Some of the finest examples of Apples were Bismarck, King of the Pippins, Gloria Mundi, Mère de Ménage, Warner's King, Barker's Seedling, Hollandbury, Sandringham, Flower of Kent, Stirling Castle, Beauman's Red Reinette. Of Pears, Duchesse d'Angoulême, Beurré Diel, Hayshe's Prince Consort and Victoria, Beurré Clairgeau, Knight's Monarch, Glou Morceau, and Forelle were best. Mr. Barron, the Royal Horticultural Society's Gardens, Chiswick, sent 100 sorts Apples and 100 of Pears; of the latter were grand examples of Duchesse d'Angoulême, Passe Crassane, Triomphe de Jodoigne, Beurré Bachelier, Marie Benoist, Beurré d'Anjou, Maréchal de Cour, and Maréchal Vaillant; and of Apples, Stone Apple, Alexander, Small's Admirable, Mrs. Barron, Golden Noble, Beauman's Red Winter Reinette.

Norfolk.—Mr. S. Castle, West Lynn, King's Lynn, sent forty-five dishes, some of these being very good, notably so Warner's King, Mère de Ménage, Yorkshire Beauty, Norfolk Beaufu, and Hawthornden.

Northumberland.—There were four exhibitors from this county. Mr. Inglis, gardener to Lord Grey, Howick, had 110 dishes Apples and 200 Pears. Of the latter very good dishes of Hacon's Incomparable, Beurré Diel, and Duchesse d'Angoulême from cordons. Some of the Apples were very small. Amongst the best were Catshead, Gravenstein, Mère de Ménage, Costard, Red Autumn Calville, Yorkshire Beauty, Warner's King, and Alfriston. Mr. Harris, gardener to the Duke of Northumberland, Alnwick Castle, sent thirty-two dishes Pears and 114 of Apples. Of the former Souvenir du Congrès, Beurre Superfin, Marie Louise, and Josephine de Malines were good. Mr. McAdam, Haggerstone Castle, sent sixty-eight dishes, some of the fruit being good, but much of it small; and from Mr. Berrie, gardener to the Earl of Tankerville, Chillingham Castle, eighteen dishes of well-coloured good examples.

Shropshire.—Mr. Jessels, Aquicote House, Newport, sent twenty dishes of rather poor fruits, and from Mr. Sherwood, gardener to J. C. B. Boroughs, Esq., Chetwynd Park, Newport, sixty-four dishes of Apples and forty-one of Pears, all of which were rather small in size.

Surrey.—Mr. Burnett, The Deepdene, Dorking, sent eighty-six dishes of Apples and thirty of Pears. Of the former very good examples of Hornead Pearmain, Cox's Pomona, and Hollandbury, and of the latter Beurré Bosc was of large size.

Sussex.—Mr. Rust, gardener to the Marquis of Abergavenny, Eridge Castle, had 100 dishes of Apples and twenty of Pears, generally of poor quality for the south of England.

Worcester.—From Mr. Ritchie, Eardenton, Gardens, Worcester, 120 dishes of Apples, and thirty of Pears. The Apples being mostly small, though well coloured.

Yorkshire.—Mr. Tindal, gardener to Sir Joseph Copley, Bart., Sporthorough Hall, Doncaster, sent about thirty dishes of Pears and a few fairly good Apples. Mr. McIndoe, Hutton Hall, Guisborough, twenty-one dishes of green Apples.

WALES was poorly represented, only three collections having been forwarded.

Denbigh.—Mr. Loundan, The Quinta, Chirk, sent 100 dishes of good fruits, the finest being New Hawthornden, Ecklinville, Warner's King, Gloria Mundi, Peasgood's Nonsuch, and Stirling Castle.

IRELAND.—Half a dozen exhibitors hailed from Ireland, some of the fruit being good, and much of it small and green.

Antrim.—Mr. C. Warwick, gardener to Lord O'Neil, Shanes Castle, Antrim, sent seventy-two dishes of generally small, though some of it fairly good, fruits.

Co. Down.—Messrs. Rogers, McClellan, & Co., Newry, sent forty dishes of good well-coloured fruits, English Codlin, Warner's King, and Catshead being best. Mr. Blackburn, Abbotstown Gardens, Castlerock, also sent a collection.

Galway.—Mr. Cobham, Garbally Gardens, Ballinasloe, sent sixty dishes, of which Alfriston, Peasgood's Nonsuch, and Cox's Orange were good.

Mayo.—Mr. R. Farrell, Westport, sent thirty dishes of good well-coloured fruit.

Sligo.—Thirty-five dishes of poor fruit came from this county.

Wexford.—Mr. Turner, Courtown, Gorey, had seventy dishes of good fruit, some of the best were Dumelow's Seedling, Cox's Pomona, Golden Noble, and Blenheim Pippin.

Wicklow.—One collection of ninety-six dishes came from this county, wanting in size and colour of fruit.

SWITZERLAND.—Herr Strasse, Insbruck, Tyrol, showed eight dishes of beautiful clear-coloured fruit, though not of great size.

NOVA SCOTIA.—From here came 110 sorts, many of these were very remarkable for size. Some of the finest were Esopus Spitzenberg, Hoary Morning, Waggoner, Harris, Biglow, Mother, Blenheim Pippin, extra; Fox Pippin, Gloria Mundi, Calashen, Fameuse, Rymer, Gravenstein, Maiden's Blush, King of Tompkins County, extra; Golden Russet, and Kaig's Spitzenberg.

HARDY FRUIT GARDEN.

Winter Pruning.—For many years it has been a settled plan with us to try and get the winter pruning of fruit trees as forward as possible before Christmas. Pears, Plums, and Cherries are usually done first, then come the Apples, bush fruit, and, lastly, wall trees generally. The only thing left late in the season is the pruning of Nuts and Filberts, all which are left till pollen is so plentiful in the catkins that the impregnation of the female blossom is insured. When the pruning is left till January cold weather not unfrequently sets in with such severity that the work is hindered, and there is some risk of spring being upon us before it is done. Therefore let no opportunity be lost of pushing on the work. Thin all crowded spur and branch growth, for without free admission of air and light among the branches the trees cannot continue healthy nor the fruit become fully developed. Often have we gone over our favorite trees again and again before we became fully satisfied with our work. Our object in pruning, too, is not only to render a tree fruitful, but to insure so far as we can the production of really fine fruit. No doubt fruit-thinning contributes materially to this, but we prefer first of all to keep lateral growth thin, and also to thin the fruit when necessary. Avoid excessive pruning of Cherry trees; they are always liable to suffer so much from severe pruning that trees so treated often die. We have lost many trees from this cause, the sorts which have suffered most being Morello, Kentish, Early Purple Gean, Duchesse de Palluan, Early Rivers, and Transparent.

Lateral growth shortened to 6 or 8 inches in August must now be pruned to two or three buds. Do not prune with a long oblique cut, but rather with a short one, taking especial care that the bottom part of the cut is above the bud, in order that there may be plenty of tissue around the base of the bud to insure a full free flow of sap to it when growth begins. Making one side of the cut below the bud is a common error, a piece of slovenly careless practice to be avoided. See that the growth of all young trees is shortened sufficiently to insure a free lateral growth, and take care that the lower branches of pyramids and palmette verriers have a sufficient start to insure robust growth before the upper branches make much progress. Do not prune the shoots of Fig trees now; thin them, if necessary, leaving enough to be tied in thickly. It is from the buds near the tips of the branches that we shall obtain the fruit crop next year.

Stake and tie securely espaliers and other trees requiring supports; also examine the supports and fastenings of newly planted trees occasionally, and see that no roots or stems become loosened in the soil.

Of bush fruits prune away the old wood of Raspberries and Blackberries, and tie in new growths for next year's crop. Raspberries are shortened to about 4 feet, it is quite immaterial whether Blackberries are shortened or not; but it is important to have new growth for fruiting and not old spurred growth. Thin out Black Currant wood, cutting old crowded growth clean down to the ground. Red and White Currants and Gooseberries may also be pruned now, and the bushes should then be

syringed well with a liquor of softsoap dissolved in hot water, and a mixture of lime and soot. See that the branches are well coated with it to keep the buds safe from the ravages of birds. Let the annual surface dressing of the whole of the soil among the bushes and Raspberries follow at once. Old hotbeds or half-decayed stable or cowhouse manure answers admirably for this purpose. There must be no digging among bushes, only the surface dressing of dung, which serves both to keep the bushes healthy and vigorous and to keep down caterpillars in summer.

FRUIT FORCING.

VINES.—*Early-forced Vines.*—When the buds in the early house that was closed last month show signs of swelling, the inside borders should receive another supply of water in the case of vigorous young Vines, and liquid manure where they are old and require stimulating, applying it at a temperature of 80° to 90°. Some good fermenting leaves and short stable manure laid in heaps or ridges on the inside borders will help the surface roots, giving heat and genial moisture to the atmosphere, and so reduce the necessity for strong fires and incessant syringing. Young canes that have not been forced early will require bending down to a horizontal position to insure an even break down to the base, but old Vines that have been some years may be tied down to the trellis immediately they are pruned. The dormant parts should be syringed three or four times a day until growth begins. Turn the fermenting materials over at short intervals, adding fresh material as necessary from the reserve ground to prevent the temperature falling below 75°—i.e., in the materials. Give a little air every day, allowing an advance to 70° or 75°, with gleams of sunshine, and the night ranging between 55° and 60° for the present. When the Vines are fairly moving all the buds show signs of breaking, remove the litter or fern from the outside border and cover with dry warm leaves to a depth of 18 inches, making them very firm, and place old lights or shutters over all, with a sharp pitch to the front for throwing off snow and rain.

Early Vines in Pots.—Pay attention to the fermenting material in pits containing these, and if every pot is stood on a pedestal built up from the bottom of the pit frequent additions may be made as the heat declines, the whole mass may be turned over without displacing them, and root-action will be steadier and less liable to a check when the pots are only partially covered or surrounded by the plunging material. Disbud and increase the temperature to 70° or 75° by day when fine, but do not allow the temperature to exceed 60° (and a few degrees lower will be better when the weather is severe) at night.

Late Houses.—The attention of growers of late-keeping Grapes cannot too often be directed to the importance of starting the Vines and helping them forward with fire heat in the spring rather than trusting to solar heat in summer, and having to fire hard in late summer and autumn to get the fruit and wood ripe, or apparently so, by November. In fine seasons this answers very well, but in ordinary seasons it is not safe, as the foliage hangs late and is liberated by a rapid depression of temperature. This sudden check, though it brings the leaves down, is not ripening, and the Grapes rarely retain their colour and freshness until the time arrives for cutting in January, and when Grapes begin shrinking on the Vines it is useless trying to keep them until May. All Grapes intended for keeping fresh and sound for some months after they are cut should now be hanging on leafless Vines that completed the year's functions by the close of November. Where the Grapes are in this condition keep the temperature steady at night at 40° to 45°, with just sufficient fire heat to dispel damp and to protect from frost. For Muscats the temperature must range a little higher, or about 50° by day, the chief thing being to prevent the deposition of moisture upon these and other thin-skinned Grapes; but fire heat, even with these, must be used sparingly, as they soon shrivel in a warm over-dry atmosphere. In damp weather, the outside atmosphere being charged with moisture, the house should be kept close, dry, and cool; and in clear weather, the nights being frosty, some fishing nets or, better still, canvas drawn over the lights, will prevent radiation and lessen the need of fire heat and reduce its parching influence to a minimum, whilst the subdued light in the daytime will help the Grapes retain colour and secure a greater equalisation of temperature.

Where late autumn vineries are required for plants the bunches, if any remain upon the Vines, may be cut and taken to the Grape room, the latter being cleansed, warmed, and ventilated. The bottles ought to be clean and filled with clear sweet rain water a few days before they are wanted, otherwise fire heat will have to be used to expel damp after the Grapes are introduced, and an excess of fire heat is quite as unfavourable to long perfect keeping as an excess of moisture. A piece or pieces of charcoal placed in each bottle is advisable. The Vines being free of leaves, each bunch should be cut to the pruning bud, and all the shoots beyond the bunches left intact to prevent loss of moisture from the berries when the atmosphere is dry. The Grape room ought to have thick or hollow walls, and dry with perfect ventilation and sufficient heating power to keep the air dry and the temperature steady at 45°. When the Grapes are cut, and before the winter occupants are taken in, all work in connection with the roots should have attention, and the pruning attended to, and the house put into thorough order ready for a fresh start when the proper time arrives. It is a pity that Vines should be made to act second to bedding plants, even at their resting period, for our experience points to the necessity of a complete season of rest for the Vines with full exposure to the atmosphere of a well-ventilated empty house. Select well-ripened prunings from these mid-season Vines for future stock, and lay them in the open air.

PINES.—During the next two months we may expect mucky sunless

weather, with long cold nights, constituting a condition not favourable to ventilation, though it may be advanced under favourable conditions, but such is not advisably enforced, nor is it judicious. A slow rate of progress should therefore be aimed at, lowering the temperature to its minimum in each compartment, that for the fruiting house being kept at 65° to 70°; 60° to 65° in the succession houses, and 55° to 60° in compartments where suckers are located. The atmosphere of the fruiting house will, in order to make the best of the fruit, require to be of an invigorating nature, and need unremitting attention. Sprinkling the pathways, and moistening other available surfaces in the house as they become dry, must be strictly accorded, and in proportion to the fire heat applied and the aridity that prevails so must the syringing of the plants be regulated. In light airy houses the plants will need dewing at least once a day, and on bright ones twice. This may be done so long as the water in the axils of the leaves are not surcharged to an extent that will affect the state of the soil around the collar of the plants—a condition that must be avoided. The plants should be examined once a week, and those that really require moisture should be given an abundant supply of tepid weak liquid manure. Plants in fermenting beds will not require nearly so much water as those subjected to bottom heat from hot-water pipes, but they must be seen to as advised and their requirements promptly met. Successional houses and nursing pits having less heat will have a more equable state of moisture, which it should be the object to maintain, employing no more fire heat than is absolutely necessary, employing night coverings as the best means of dispensing with fire heat, and securing an atmosphere favourable to the steady progress of the plants. Let the plants have the full benefit of light and sun, closing early.

PLANT HOUSES.

Poinsettias.—The brilliant scarlet bracts of these plants are more serviceable for various forms of decoration after Christmas than they are before. Perhaps the worst month in the year for flowers is January, and if grown specially for that period they will prove invaluable. If they have enjoyed an intermediate temperature only since they were removed from the cold frames they will now be dwarf and sturdy, with bold leathery foliage down to their base. The bracts will have commenced forming, and if the plants are required previous to the time indicated they should be brought forward in a temperature of 60° to 65°. The plants should be arranged close to the glass, for light and heat are essential to develop large well-coloured bracts. If the plants are not wanted they should be allowed to remain in their present position, where they will steadily unfold fair-sized heads. It is much better to sacrifice a little in the size of the heads than to have them in full beauty at a time when scarlet is plentiful. If the plants are to be employed for conservatory or other comparatively cool structure they must be carefully prepared for the purpose. If they are forced in heat and removed directly from a close moist structure to a cool one their foliage is certain to suffer, and then half the real beauty of the plants is destroyed. When grown in strong heat it is important that they be hardened judiciously for decoration in a cool house, or they will not last half the time they are capable of doing. When grown in an intermediate house they can be removed to the conservatory without preparation, for no check will be occasioned by the slight difference in the temperature. Weak stimulants should be given every time water is needed.

Euphorbia jacquiniæflora and *Centropogon Lucianus*.—These should still be grown in an intermediate house, for they are not yet wanted either for the stove or the conservatory. These two plants are invaluable for either position, and will be found of great service after Christmas. Both structures are now very gay, the former with *Plumbago rosea* and *Begonias* of various kinds, while plenty of scarlet can be maintained in the latter by *Zonal Pelargoniums*, which at this season are indispensable. All plants of this description that can be retarded for use at that period should be, for care in this respect renders the forcing of greenhouse and hardy plants easy and certain. However, if previous directions have not been carried out, and these plants must be brought into bloom, the same care must be exercised in hardening them before placing them in the conservatory as advised for *Poinsettias*.

Eranthemum pulchellum.—For the supply of blue flowers for the stove, intermediate, or warm conservatory few plants equal this old inhabitant of our plant houses. Its flowers, which are produced successionally, are not of much service for cutting, but they are indispensable for associating with other flowering plants in pots at this season. There is generally at this time of the year a scarcity of blue flowers, and therefore this old plant should be grown, for plants in various sized pots from 5 to 10-inch when well bloomed are very effective amongst others. Those grown for this purpose should be brought forward in succession, and a supply of blue flowers can thus be maintained until *Hyacinths* are plentiful.

Begonias.—Such kinds as *B. manicata* and *B. horacleifolia* will bear cooler treatment than many suppose, for our plants have remained in perfectly good condition in a cool house in which the atmosphere has been kept dry. They will now be given a temperature of 50°, while a portion will be removed into a higher temperature to bring them into flower. If they are all given the same temperature they come into flower at one time, and are therefore not so useful. When these plants are in flower they are invaluable for the conservatory where light effective arrangements are required, for the plants can be so arranged that the flowers rise above many other plants. The first named is the lightest in appearance, but it is not so telling as the larger pink flowers of the latter, which also lasts in perfection a greater length of time. In whatever structure these plants

are placed the atmosphere must be kept rather dry or the foliage will decay. Such sorts as *B. weltoniensis*, *B. Dregei*, *B. parviflora*, and others that have been resting in a cool place, may now be started into growth for flowering early in the season. These will soon commence advancing if watered and placed in a temperature of 50° to 55°. Then they should be turned out of their pots, the old soil shaken from their roots, and the plants placed into the pots in which they are intended to flower. They do well in a compost of fibry loam, leaf mould, and manure; the latter should be passed through a sieve, a liberal dash of coarse sand added.

THE FLOWER GARDEN AND PLEASURE GROUND.

Fallen Leaves and Leaf Soil.—The leaves have fallen somewhat earlier than usual, the whole of them in most localities being off the trees, this much simplifying the work of putting the lawns, beds, and borders in good order for the winter. It is useless to clear the lawns and borders without also doing something to prevent the leaves in the shrubberies from being driven on to them again whenever a strong wind prevails. Where they can safely be allowed to remain they will decay and benefit the shrubs, but otherwise they must either be lightly dug in or collected and converted into leaf soil. Some are in the habit of burying great heaps of leaves in any convenient hole, but unless these holes are emptied occasionally, and the well-decayed contents utilised, the practice must be considered a wasteful one. Good leaf soil is almost invaluable to the flower gardener, no material added freely to a compost better suiting delicate seedlings, newly struck cuttings, as well as strong plants; while if it is freely stirred into the surface of the beds intended to be planted more especially with *Violas*, *Verbenas*, and *Begonias*, it will induce a free growth, and not readily permit the moisture of the beds to evaporate. The very best leaf soil is that naturally formed in the woods, or which has drifted into dry ditches. This may be well collected at times when other work is not pressing, and when sifted over and all decaying sticks separated from it, a valuable addition to the potting soils will be secured. Much of the leaf soil formed in the frame ground or in heaps elsewhere is not unfrequently spoilt by over-heating, this resulting in a spread of mould or dry fungus through the heap, and which has quite a poisonous effect on the roots of many delicate plants placed in it. Heaps of leaves intended to be converted into good leaf soil should be frequently turned, especially when they are found to be heating strongly, and this will insure decomposition without fungus being encouraged. Oak leaves are the best, next Chestnut and Elm.

Flower Beds.—If the various bulbs intended to beautify these in the spring are not planted, no time should be lost in getting them in. Unless covered by 2 or 3 inches of soil frost may injure them, and as a further preventive the beds may well be surfaced over with not less than an inch of cocoa-nut fibre or leaf soil. Spring-flowering plants not being available, the beds may be made to present quite a bright appearance by a judicious arrangement of short neat pieces of variegated *Hollies*, *Box*, *Aucuba*, *Mahonias*, and *Tree Ivy*. All our carpet beds have a groundwork of hardy plants, such as *Sedum glaucum*, *Antennaria tomentosa*, *Veronica repens*, variegated *Arabis*, and *Herniaria*, and these, as well as the *Golden Pyrethrum*, are not disturbed, but the figures are filled in with *Ajuga reptans rubra*, small *Beetroot*, *Sempervivum californicum*, neat sprays of coloured *Mahonia*, *Box*, *Hollies*, *Aucuba* and *Ivy*, with small *Cupressus*, *Retinosporas*, and *Iris foetidissima variegata*, the three latter being used for dotting or single prominent plants. In this manner a very pretty effect is easily attained, and which appears to give more pleasure than even the summer occupants did. Other conspicuous beds are also decorated in a somewhat similar manner, this being preferable to naked soil, and obviating the employment of plants that would look dull all the winter, and would, as a rule, flower when there was no one here to see them. Where the beds are not filled in any way, they, if the soil is naturally clayey or of a bad working character, should be dug as roughly as possible, in order that the frosts of winter, or wind and rain of the spring months, may thoroughly pulverise them. It should also be remembered that many bedding plants are great exhausters of the soil, and unless something is done to restore some of the lost fertility, the next occupants cannot reasonably be expected to thrive satisfactorily. Now is the time to manure the heavy soil, and half-rotten leaves or stable manure, or, better still, a dressing of decayed garden refuse, is suitable for the purpose. In the case of naturally light or very free working soils, these are best manured and dug in the spring, all rubbish being cleared off at the present time. When such soils are manured and dug in the autumn they become too finely divided, and are liable to have much of their fertility washed out of them, besides becoming cold and sodden.

Draining Shrubberies.—When choice and even common trees and shrubs are planted on cold undrained positions, the wonder is, not that they refuse to grow, but that they keep alive so long as they do. Too often much of the work of planting shrubberies is completed without any regard being paid to the state of the drains, and from experience we find it very unwise to trust to any natural system of drainage. In one instance that came under our notice a large number of *Wellingtonias*, *Cupressuses*, *Cedrus Deodara*, *Salisburia adiantifolia*, and other *Conifers* and shrubs would only grow in places owing to the subsoil being a cold badly drained clay, the water frequently laying on the surface for days. As it was almost impossible to provide a suitable outlet for drainage, a good-sized hole was formed at a distance from the trees, and to this surface or open drains were led. The effect was most surprising, the trees during the following summer making strong and healthy growth. This afforded most convincing proof that a well-drained and very clayey soil will grow almost anything, and the trees will attain much larger dimensions than they do on lighter and apparently much more suitable soils. Not many

drains are required, over-draining frequently proving nearly as injurious as no draining at all. On heavy clayey land we would dispose them about 12 feet apart and 3 feet deep, while land of a medium texture would require rather fewer drains, these, where possible, being disposed rather deeply in order to prevent a too rapid drainage. Surface drains are advisable when the ground has been trenched and the clayey subsoil brought to the surface, this, during the process of planting, becoming like so much puddle, and preventing the ingress of either water or air. Trees planted in such uncongenial surroundings ought to have a liberal quantity of good light soil, including plenty of leaf soil worked round and about the roots, and from this they will gradually spread into the surrounding soil, always supposing it is properly drained, and therefore rendered warmer and sweeter than it otherwise would be.

THE BEE-KEEPER.

ARTIFICIAL SWARMS FROM SKEPS.

THE man who first discovered and gave to the world in a practical form the art of artificial swarming, conferred an inestimable boon on all apiarians, and one the full value of which is year by year becoming more widely recognised and made use of; so much so, indeed, that in the not distant future a natural swarm will become a rare phenomenon or a luxury enjoyed only by those who can afford to risk the loss of a swarm, or are so continually in the bee garden as to obviate any chance of such loss taking place. There are several ways of forcing swarms, each one differing slightly from the other, and being in some cases more suitable than the method which in another case may be the wiser one to follow. The usual way of taking an artificial swarm from a skep is to drive two thirds of the bees, with the queen, into an empty hive, and place the old stock from which the bees have been driven, not less than 4 feet on one side, and the swarm 4 feet on the other side of the old stand. The object of this is to avoid a great number of bees deserting either the swarm or the old stock, and so either materially weakening the swarm or imperilling the brood, upon the hatching of which the future prosperity of the stock must entirely depend. This is the simplest plan, and it is not necessary to see the queen, as her presence in either hive can at once be detected by the behaviour of the bees, which will, if the queen is not with them, run about in a state of wild excitement seeking her. If the swarm evinces these signs the old stock must be drummed again until the queen goes with the swarm, for the presence of the queen with the swarm is an absolute necessity.

All other plans are but adaptations from this one, and it would not be necessary to enter into any other method in detail, if it were not well known that many bee-keepers are quite unable to have their hives so far apart as to allow the requisite displacement necessary to insure success, although some say that if the hives are placed even less than 4 feet on either side of the old position, and the entrance is disguised for a few days, all will go on well. Suppose, then, three hives are standing in close proximity to one another, and it is desired to take a swarm from each of them, there is ordinarily no little misgiving as to whether the operation can safely be performed.

By the following method, which is not objectionable except that it sometimes incurs a little extra expense, such difficulty can be overcome. The method is to get a friend living at a distance of at least two miles to exchange or sell a swarm. The effect of this will be to facilitate the operation. From each of the three stocks drive all the bees into three separate hives, and place each swarm on its old stand. Here, then, we have three swarms of unusual strength, and three stock hives filled with comb, brood, and honey. We next divide the strange swarm into three equal parts, and to each stock give one part, and place it in any convenient spot. There can be no failure, and if a swarm of equal weight is sent in return for the one made use of in the operation no expense is incurred at all. Even if an exchange cannot be effected, in country places a swarm never costs a sum so large that a

man need hesitate to buy one, for he may confidently expect a speedy return of this outlay, with good interest for his money.

There is yet another way, which may with advantage be mentioned, as giving good results, although in this case half a swarm can only be taken, and room on one side of the end hive is necessary to allow a slight displacement of 3 or 4 feet at the least. Let us take our three stocks again, and explain the plan, which is well known amongst bee-keepers, and has been considered a valuable one by eminent apiarians. From one of the stocks—not being the one which gives room for displacement—drive out all the bees and the queen, and these being placed in the old position, form the swarm. We have then a hive, as before, of comb and brood and honey. The next thing is to place the end stock on a new stand, not less than 3 or 4 feet from the old one, and then place the stock from which all the bees have been driven on the exact position occupied by the stock which has been removed some feet away. This operation should only be performed on a warm sunny day, when many bees are on the wing, as the object is that the bees returning home may enter the hive—placed in the position of the one they left when they went to work—remain in it, and raise a queen while sufficient bees are left in the removed stock to hatch out its brood, which will soon make the hive so populous again that scarcely any reduction will be perceived. The same operation can then be performed with the stock which has not been moved, and so on until the bee-master is satisfied. Second swarms will issue from each of the stocks, but these should be returned a few hours after their issue. This will prove, in the hands of capable men, a safe substitute for the other and more usual methods of forcing swarms, and will also, by reason of only taking half a swarm from each stock, insure a surplus of super honey.

One word of warning must be given with regard to artificial swarming, and that it is better to err by being a week too late than a week too early. No stock should be compelled to give a swarm until the bees are numerous, the brood is filling nearly every comb, and drones are hatching out; and it is safer to leave too many bees in the old stock than to leave too few. If the weather is unfavourable the swarms must be fed, and occasionally the old stock may require a little assistance, as there are many hungry mouths to feed, and, for some days, few labourers to gather food. Assist Nature when possible, but remember that if man interferes with Nature's laws he alone is responsible for the success or failure which rewards his efforts.—FELIX.

GENERAL MANAGEMENT OF BEES AND HIVES.

(Continued from page 482.)

IN addition to large hives with plenty of bees being two essentials towards profitable bee-keeping, equally so are the two following—viz., young fertile queens and new combs. After these four cardinal points come the questions of quantity and quality. The first of these is sure to follow when the foregoing essentials have been rigidly carried out. Quality ought to be the primary object, to obtain which there need be little or no sacrifice as to quantity by adhering to the rules I have so often laid down, and by taking the advice of "Felix" to study economy. Bee-keepers will at once recognise their true position on the question of profit and loss by keeping a strict account of expenditure and income, as well as proving that a first-class sample of honey or honeycomb is as easily produced as an inferior one. Finding a readier market and a higher price consequently is the thing that will place the higher figures on the right side of the balance sheet. Not only is it desirable, but it is absolutely necessary in many cases, to shift bees from one place to another, particularly to the Heather, even though it should be at a distance of 100 miles or more, where rail or steamer is available. There is a demand for Heather honey when white or Clover honey is unsaleable, and bee-keepers will naturally turn their attention to securing that which is in demand.

Whatever the advantages may be that we claim in double-cased and broad hives, these in some cases must be relinquished in preference to the more handy single-cased ones or the double-cased narrow ones, twelve of which occupy less space than a dozen of the double-cased brood hives will do. When we take into consideration

that hives of the narrow type cost on an average 5s. each in taking to and bringing from the Heather, the great saving effected will be apparent. The ease in handling is also sufficient for every one to adopt single-cased hives, which are easily protected during summer by mats suspended loosely on the sides and packed above with hay, or rather long grass, so as to encourage the filling of snpers. Hives protected in this manner and covered on the top with a piece of oiled paper to throw off the rain cannot be surpassed by the more costly double-cased hives. Placed in a suitable beehouse or proper made outside cases, single-cased hives are in this way cheaper, more easily and better protected, and are easier of manipulation than the large double-cased ones. There are many more advantages that can be claimed for single-cased hives, which the bee-keeper will soon find out if he adopts them.

The yield of honey is greatly increased by husbanding and utilising comb from the preceding year, such as partly filled supers or combs in frames or straw hives built by condemned bees. It must be observed, however, that combs built the previous year, though filled rapidly by the bees, do not possess the same degree of purity as combs built the current year; for dripping or extracting purposes, so long as no brood has been reared in them, they are excellent. To maintain a good standard in the quality of honey the combs ought to be thoroughly sealed before dripping or extracting, and to obtain the greatest quantity a good supply of built-out combs should form part of the stock, obtained as mentioned above. Before removing to the Heather, adding young queens and joining two or more hives together will have the same effect; while the more empty comb the greater will be the ingathering of honey. Hives so treated will be in the best possible condition to stand the winter and commence anew as the days begin to lengthen, which has a positive beneficial influence on stocks by the necessary agitation in keeping up a uniform degree of temperature in carrying on the internal economy of the hive, even while the temperature stands at zero. It has always been observed that hives breeding early in January are more healthy than those that perforce have to delay till March.

The great question in successful bee-keeping is to keep strong hives, preserving them in that state by carefully avoiding everything that disturbs and causes loss of bee life; and the best way of securing that is to follow closely the foregoing instructions, and let all manipulations be as few and far between as possible. The fields furnish flowers and the honey which the bees collect; the more numerous these are in the hive the more honey will be collected and stored in the proper place. It is but a poor expedient having to invert hives for the purpose of getting supers filled, and points either to a poor district or something radically wrong in the management.—A LANARKSHIRE BEE-KEEPER.

TRADE CATALOGUES RECEIVED.

Benjamin Field, Swan Place, Old Kent Road, London.—*List of Horticultural Sundries.*

Hogg & Wood, Coldstream and Duns.—*Catalogue of Nursery Stock.*

TO CORRESPONDENTS

* * All correspondence should be directed either to "THE EDITOR" or to "THE PUBLISHER." Letters addressed to Dr. Hogg or members of the staff often remain unopened unavoidably. We request that no one will write privately to any of our correspondents, as doing so subjects them to unjustifiable trouble and expense.

Correspondents should not mix up on the same sheet questions relating to Gardening and those on Bee subjects, and should never send more than two or three questions at once. All articles intended for insertion should be written on one side of the paper only. We cannot reply to questions through the post, and we do not undertake to return rejected communications.

Books (C. E.).—We do not know a pronouncing dictionary such as you require. In the "Cottage Gardener's Dictionary," published at this office, post free 8s. 3d., you will find brief cultural directions, and the names of the plants are accented as a guide to the pronunciation. A temperature that does not fall below 48° will suit your Pelargoniums.

Cactaceous Plants (D.).—Write to Viccars Collyer & Co., Leicester, and to Mr Boller, Woodfield Nursery, Harrow Road.

Variegated Fern (*J. G.*).—The frond of *Pteris serrulata* is clearly variegated, and if the character is maintained and the plant grows freely it will be very attractive for table and other purposes of decoration. We have not seen an example in which the white is so pure.

Poinsettias Failing (*J. L. E.*).—As the plants were so sturdy and vigorous by being grown outdoors in the summer, we can only suggest that their failure to produce good bracts is the result of the plants being left out too long. When they remain in cold positions until the leaves droop, growth ceases, and the roots first become torpid, then shrivel or decay. If you examine the roots of your plants and they are dead or brown in colour, you may conclude we have either indicated the cause of the failure or you have given them an overdose of liquid manure. We feel confident the roots are not fresh and active, in which case it is impossible that large whorls of brilliant bracts can be produced.

The Trout Pear (*B. D.*).—Undoubtedly there is a Pear known under this name, that being a popular synonym of the Forelle Pear, which is described in the "Fruit Manual" as follows:—"Fruit medium sized; oblong obovate, but sometimes assuming a pyriform shape. Skin smooth and shining, of a fine lemon-yellow colour on the shaded side, and bright crimson on the side next the sun, covered with numerous crimson spots, which from their resemblance to the markings on a trout have suggested the name. Eye small, set in a rather shallow basin. Stalk an inch long, slender, inserted in a small shallow cavity. Flesh white, delicate, buttery, and melting, with a rich, sugary, and vinous flavour. An excellent Pear, in use from November till February. The tree is hardy and a good bearer."

Notes (*An Old Subscriber*).—We are obliged by your letter, which is one of several widely differing in tone. It is, we presume, not sent for publication, or it would illustrate what you very properly condemn. We coincide in your views on the main question, but if you could see what we do not print you would, perhaps, be more surprised than ever.

Mushrooms Outdoors (*Scotch Mist*).—The long lapse of time before Mushrooms appeared was no doubt mainly the result of the temperature falling too low after the mycelium had permeated the mass, or in other words after the spawn had run. Mushroom spawn remains quiescent for a long time under a low temperature, and does not appear to be materially weakened thereby. Beds that have been quite frozen in the winter have produced good crops of Mushrooms in the spring. It is evident the bed to which you refer was warm enough for a time or the mycelium would not have spread, but the temperature fell too low during the cold weather that followed for inciting the production of Mushrooms. If a thermometer laid on the surface of the bed or ridge under the covering registers 50° the interior will be upwards of 20° higher, and if the material be good and the spawn strong Mushrooms will push through the soil freely. Two works on market gardening are Earley's, which treats on outdoor crops, and Shaw's, which includes plant culture as well. The first is published at 170, Strand, London, the other by G. Routledge & Sons, Ludgate Hill.

Cutting Back Roses in the Autumn (*H. G.*).—Your plan of shortening the strong roots in November—that is, the long loose ends that have an untidy appearance, cannot possibly weaken the plants, but on the contrary, as you observe, it has a tendency to cause the lower buds to swell somewhat, and these buds have to be relied on for strong growth and fine blooms. If shortened too severely in the autumn these lower buds often start too soon in the spring and the young shoots are cut by frost, but as you say you have the growths about 3 feet long that is certainly not close autumn pruning. Many good growers both thin out weakly growths and remove the ends from the stronger in October with excellent results, as the strength of the plant is then not wasted on useless portions, while the growths left are assisted to ripen by being more directly exposed to the sun and air. It is a mistake to suppose that the sap in the ends of the shoots removed would, if they were left uncut, return to the roots during the winter and feed them. There is little or no nutrient matter deposited anywhere by the necessarily soft unripe ends of the growths, and what there is is secreted before the leaves fall in the wood and round the buds, chiefly remaining there for their nourishment. The method you adopt is, in our opinion, perfectly sound, and the excellent results you obtain suggest there is nothing to be gained by any departure from it.

Popular Roses (*J. Melton*).—If you mean by these, Roses that are the most generally grown for exhibiting, the following fifty Hybrid Perpetuals and twenty-five Teas and Noisettes will answer your purpose:—La France, Marie Baumann, A. K. Williams, Baroness Rothschild, Marquise de Castellane, Madame Gabriel Luizet, Charles Lefebvre, Captain Christy, Alfred Colomb, François Michelin, Etienne Levet, Duke of Edinburgh, Marie Rady, Louis Van Houtte, Dr. Andry, Marguerite de St. Amand, E. Y. Teas, Comtesse d'Oxford, Merveille de Lyon, Madame Hippolyte Jamain, Duchesse de Valmore, Horace Vernet, Madame Lacharme, Madame Victor Verdier, Marie Verdier, Fisher Holmes, Beauty of Waltham, Duke of Wellington, Pride of Waltham, Sénateur Vaisse, Camille Bernardin, Dupuy Jamain, Le Havre, Xavier Olibo, Comtesse de Serenye, Star of Waltham, Marie Finger, Abel Carrière, Eugénie Verdier, Mrs. Charles Wood, Général Jacqueminot, John Hopper, Ferdinand de Lesseps, Countess of Rosebery, Monsieur Noman, Edouard Morren, Prince Arthur, Duke of Teck, Ulrich Brunner, Duchesse de Morny, Teas and Noisettes—Souvenir d'un Ami, Maréchal Niel (N.), Catherine Mermet, Marie Van Houtte, Niphetos, Souvenir d'Elise Vardon, Jean Ducher, Innocente Pirola, Devoniensis, Caroline Kuster (N.), Rubens, Comtesse de Nadaillac, Souvenir de Paul Neyron, Madame Willermoz, Anna Ollivier, Etoile de Lyon, Alba Rosea, Perle des Jardins, Madame Lambard, Belle Lyonnaise, Madame Bravy, Madame Margottin, Madame Angèle Jacquier, Madame Welche, La Boule d'Or.

Planting Marechal Niel Roses in Chrysanthemum House (*Cambridge*).—We presume you do not desire to cover the body entirely, but only thinly or partially, so as to admit light to Chrysanthemums in the autumn. This being so, we question if there is a better plan than that adopted by Mr. Gilbert at Burghley, which enables him to produce the greatest number of fine blooms, while at the same time admitting light to trees and plants. The Burghley example was alluded to as follows in March, 1893, by the writer of these lines:—"In one house Figs covered the back wall, with Maréchal Niel Rose on the roof in grand condition. We have seen many

remarkable examples of this fine Rose, one of them bearing three thousand blooms, but the Burghley specimen surpasses them all as a type of high culture. It is on the Briar, and fortunately worked low, as ought always to be the case when this Rose is worked at all. It is planted in the centre of the house and close to the front, horizontal main branches being trained right and left along the base of the rafters. These horizontal mains are the only permanent portions of this fine tree. At intervals of 5 or 6 feet wires are stretched up the roof, and to these are secured the flowering shoots; and it is to be particularly noted they are annual shoots—that is to say, as soon as the blooms are cut in May or June the growths are cut quite down to the base of the rafters. The roots being in rich soil and generously fed, strong growths start at once, and four or five of these are trained up each wire. They speedily reach the top, and are then shortened. These young growths are fully as thick as an ordinary pencil and many of them much thicker, while the foliage is remarkable for its size, substance, and deep rich green. One of the leaflets casually measured exceeded 6 inches by 5, exclusive of the footstalk. When it is remembered that every bud on wood thus prepared affords at least one flower, some idea may be formed of the pendent massive lines of golden blooms that must be produced. The effect cannot but be magnificent and worth a long journey to see. This is the simplest and best of all systems of growing the Marechal Niel Rose under glass. We have proved its value years ago and seen the plan carried out by others, but never so well as in the example under notice. The wires are placed at the distance stated, so that the Figs on the back wall received the light between the cordons of Roses. The stock of the Marechal, as is almost invariably the case, has increased much faster than the Briar. This is the cause of the death of many fine plants, or rather trees, when budded high, but worked low the junction can be covered with soil. This is what has been done at Burghley by packing a wall of turves round the stem after a sharp knife has been drawn down the Briar portion, cutting quite through the bark, and it is expected the health and vigour of the specimen will be maintained. The roof under which this Rose is trained is 30 feet long by 18 or 20 deep. Worthy of record as are many doings at Burghley, not one is more worthy than this splendid instance of Rose culture. To that it is only necessary to add, if you wish to have wires covered with growths as quickly as possible, you had better plant one Rose for each wire. If you commence at 2 feet from the ends of the 24-feet compartment you will have space for three wires on each side with intervals of 8 feet between them. In the other compartment you can either have two wires up each side at wider intervals than stated, or three a little closer; or either ten or twelve plants altogether. In this way you might grow numbers of Rose blooms without materially depriving Tomatoes of light in the summer or Chrysanthemums in the autumn. You ought to have very strong plants of Tomatoes by the first week in May. The soil for the Roses cannot well be too rich, and the plants should be pruned quite closely after planting. Many Marechal Niel and other Roses are ruined by having long shoots before root-action is powerful.

Names of Fruits.—The names and addresses of senders of fruit to be named must in all cases be enclosed with the specimens, whether letters referring to the fruit are sent by post or not. The names are not necessarily required for publication, initials sufficing for that. (*J. W. H.*)—The portion of fruit sent is of the Forelle or Trout Pear. See reply to another correspondent. (*C. W.*)—1, not known; 2, Comte de Lamy; 3, Bergamotte de Jodoigne; 4, Maréchal de Cour. (*Slinketh*).—1, General Todleben; 2, Doyenné Goubault; 3, Golden Reinet; 4, Scarlet Nonpareil; 5, Adams' Pearmain. (*James Pound*).—5, Beurré de Jonghe; 10, Ne Plus Meuris; 16, Duchesse's Favorite; 19, Striped Beefing; 22, Claygate Pearmain; 23, not known. (*J. T. S.*)—1 and 2, Beurré Diel; 3, not known, worthless; Apple, Golden Russet. (*Walter Kruse*).—Prince Albert.

Names of Plants.—We only undertake to name species of plants, not varieties that have originated from seed and termed florists' flowers. Flowering specimens are necessary of flowering plants, and Fern fronds should bear spores. Specimens should arrive in a fresh state in firm boxes. Slightly damp moss or soft green leaves form the best packing, dry cotton wool the worst. Not more than six specimens can be named at once. (*A. Ratty*).—1, *Zygopetalum Mackayi*; 2, *Hedychium Gardnerianum*, which can be grown in a good compost of loam and old manure in an ordinary stove, though it succeeds very well in a greenhouse during the summer.

COVENT GARDEN MARKET.—DECEMBER 2ND.

TRADE very quiet. Heavy supplies of Grapes making exceptionally low prices. Large arrivals of Nova Scotia Apples at lower rates.

PLOUGHING IN GREEN CROPS.

"In your issue of October 8th, page 329, I notice it is stated with respect to green manuring that a green crop of White Mustard contains per acre half a hundredweight of phosphoric acid, a hundredweight of nitrogen, and a hundredweight of potash; and that by ploughing in two successive crops the second crop adds considerably to the rich store of fertility already obtained by the first crop." Thus writes "Auricula;" and he adds, "I shall be glad to learn from whence the phosphoric acid and the potash are derived. If from the earth, then in ploughing in the crop you return to the soil only that which has been taken out of it." To this we might be content to reply that phosphoric acid is a compound of one atom of phosphorus with fifty-nine of oxygen; that the affinity of potash for oxygen is very great, and that out of 100 parts of the composition of plants upwards of forty parts are oxygen derived solely from the air and rain, and, therefore, that the ploughing-in of green crops is something more than "a return to the soil of that which has been taken out of it." But the query of our correspondent is by far too important to be dealt with thus summarily, and we gladly seize the opportunity to enforce strongly upon our readers the importance of a clear knowledge of the influence of natural laws upon our work of cultivating the soil.

Fixed natural laws influence the phases through which the plants of the farm pass to full development. Of the four organic elements of our green crops three are always present in almost invariable proportions. These are oxygen, hydrogen, and carbon. Taking 100 parts of the composition of the plants of green crops we find that 93.55 parts consist of oxygen, hydrogen, and carbon, and they are all derived from the air and rain. Pray try and grasp the full significance of this wonderful fact, and you will then see how the gases of air and rain, in combination with other elements of fertility drawn from the soil, combine to develop and store in stem, branch, leaf, flower, and seed a rich store of nutriment, much of which enters the soil when we plough in a green crop. No doubt it is the general inattention to the influence of air and rain upon plant growth that tends to hinder the full recognition of the value of green crops as manure, and yet it is constantly before our eyes. Said a worthy farmer to us once, "I have frequently noticed that when a heap of Turnip tops is left to rot upon the soil there is sure to be a patch of growth there of a deeper hue and more robust growth than elsewhere in the next crop." Yet he had not been able to comprehend and apply to practice this plain teaching of Nature.

It is, however, by no means intended to infer that because the gaseous elements of the air in combination with heat contribute so largely to the substance of plants that the other elements are unimportant. Take, for example, two plots of poor land. Let them both be well stirred and sown with Mustard seed; leave one plot then to mature. Sow upon the other nitrate of soda at the rate of a hundredweight an acre, and mark the difference. The nitrogenous manure acts like a charm, causing the elements of fertility in air and soil to blend in happy combination, and the result is vigorous robust growth, in striking contrast to the comparatively puny growth upon the other plot. That this single application of nitrate of soda is sufficient is shown when we plough in the green crop and sow another. A yet stronger growth follows, telling us plainly that of all the elements of plant food necessary to insure robust growth nothing is wanting, the decay of the first crop in the soil storing it with nutri-

ment. This fact is, perhaps, the best answer as to the value of ploughing in green crops. Agricultural chemistry is apt to be considered a dry subject, but let farmers only be made to see that the study of it confers knowledge and an insight into natural laws leading to results that are literally golden, and surely they will not be slow to acquire such knowledge.

A disadvantage attending the use of artificial manures is slowness of action, but a soft green plant is comparatively so soluble that the elements of fertility are soon set free and are quickly available for plant food. Nor must we overlook a still more important consideration, and that is the economy of the process. Undoubtedly pure artificial manures mixed on the farm are preferable to farmyard manure on the score of economy, but green-crop manuring enables us to avoid manure bills, the only outlay being the cost of labour in ploughing and sowing. Doubtless this fact will tend to enforce attention being given to it more than anything else can do, for in the present agricultural depression we are bound by stress of circumstances to practise rigid economy. We are also bound to render and keep the soil fertile, our aim also being to see if by superior cultivation it is not possible to wrest something more from the soil, to improve the quality as well as increase the bulk of our crops. Depend upon it the ploughing-in of green crops is a step in the right direction. To all doubters we say, Give the matter a fair trial next season. If you have land foul with couch grass watch for the first opportunity of stirring and clearing it in spring, then sow it with White Mustard at the rate of 20 lbs. of seed per acre; if poor, give a dressing of nitrate of soda, plough in the Mustard as soon as the plants are in full flower, and your land clean and fertile will be ready for a crop that will pay.

WORK ON THE HOME FARM.

Fine open dry weather has been turned to account for corn-threshing, and the work has been done well and quickly. All straw left in the open air has been carefully stacked and thatched at once. No slovenly leaving about of straw heaps should ever be passed; this is a matter that has given us some trouble—so, too, has the too common tendency to leave implements about exposed to the destructive action of the weather. It should be an inflexible rule that no tools or implements should be left out after each job of work is done. Cleaning and painting should also be done in time. A man who is careful in such thin s will generally be found worthy of trust in others. Look well to water furrows on fresh ploughed land. As the ploughing or sowing of each field is finished the water furrows should be continued with a spade into the nearest ditch. Some judgment is required in the making of water furrows, especially on hill farms, serious injury frequently being done during heavy rain or in a thaw after snowstorms. It is bad practice to make water furrows from top to bottom of long slopes. The correct line to follow is a gentle diagonal one across the slope, and there should be enough of such furrows to prevent any serious surface washing. On open mixed soils very little care is required; but there must be plenty of well-arranged furrows on heavy land and close silicious soils. See that the outlets of drains and all watercourses are open, and arrange that there shall be a regular periodical inspection of such places, as well as of pond banks. Upon one of our home farms we have several ponds down a valley that at one time were a source of annoyance from fractures in pond dams at flood times. We soon learnt the importance of making substantial dams high and wide, with a safety opening at what may be termed high water mark with a special channel to take flood water. Such work must be well done. Once get a fissure in a bank, a loose stone or two in a cascade, and down may go bank or cascade during some flood time in winter. Two seasons of severe drought have given point to the importance of water storage at this season of the year for cattle in summer. There are few farms where such storage may not be managed. We recently heard a complaint that a piece of land could not be drained because it was so low in the middle of it. We at once said, Excavate a pond in the low place, drain into it, and you relieve your land of water and provide a store of it for summer.

NITROGEN IN THE SOIL.

EACH of the elements required for building up the frame of animals and plants is of equal importance from a scientific standpoint, but in agriculture the various salts and substances which yield food for crops or for cattle must necessarily be valued according to their cost. There are exceptions to this rule, no doubt. Gypsum is a cheap manure, but it has sometimes doubled the Clover crop, and kainit salts are comparatively cheap. Yet for some crops, especially Potatoes, in cases of a deficient supply of potash in the soil, they have sometimes proved invaluable. In general, however, cost and efficiency are closely associated, and as plants and animals are almost alike in their chemical composition the same rule as to

the value of their constituents holds good. You may purchase starch and the carbo-hydrates at a much lower rate than the nitrogenous substances in food. Turnips, Bread Fruit, and Bananas, consisting chiefly of carbo-hydrates, are sold by their respective growers at a very different and much lower price than milk or Peas, which are rich in albuminous elements. In every form nitrogen is always comparatively costly. The albumen in eggs, the fibrine in cereals, the casein in milk, and the legumin in Peas and Beans, all owe their importance and cost to this particular element, which is the source of force and vigour, of the labour of the hardest-worked cattle and men, of lean meat and muscle.

Considering the limited supply of nitrogen and the cost of obtaining it, it is not surprising that it should often be present in cultivated soils in quantities insufficient for a full crop, and that the land, when dressed with salts of nitrogen, should answer to their touch as a horse does to the spur. In the Rothamsted experiments the unmanured field yielded for years about 14 bushels, or half a crop, till a dressing of nitrogen was given to it, when immediately the crop was doubled, nitrogen having been, as it often is in clay soil, the one thing needful to a full crop. Sir John Lawes has been sometimes asked by American farmers how to restore the exhausted fertility of their fields, so that the land, yielding 14 bushels per acre, which is about the average of corn-exporting countries, might be induced to return twice as much. It is fortunate for English farmers that Sir John can only send advice into the far West; he cannot send nitrogen.

Some years ago the agricultural community was flattered by the immediate prospect of a never-failing supply of nitrogen. The marvels of chemistry and analysis had recently been unfolded by the writings of Sir H. Davy and Baron Liebig, and the efficacy of guano had accustomed farmers to the new method of supplying nitrogen to the land in concentrated forms and from sources outside the farmyard. Then came the promise of obtaining nitrogen from the atmosphere. The agricultural classes are rarely much moved by anything but bad weather and falling prices, and the chemists had explained to them that the nitrogen of the atmosphere, existing as it does in a free state mixed with oxygen, was not available for agricultural purposes. If it could be induced, they were told, to enter into combination with hydrogen the result would be ammonia, an invaluable manure. This was understood by farmers, and a great sensation was occasioned among them when Mr. Nasmyth, the inventor of the steam hammer, proposed to control the supply of the most costly of plant constituents by knocking it out of the atmosphere. It is easy to see that if Mr. Nasmyth had succeeded in knocking nitrogen and hydrogen into combination at a moderate cost, a revolution in the price of manures and of food must have speedily occurred.

But as the plan failed and as plants still "live and move and have their being" in the midst of an element which they cannot feed on, it was certainly surprising to learn lately that nitrogenous manures had ceased to produce their accustomed effect. The phenomenon occurred at the Duke of Bedford's experimental farm at Woburn, where, according to official statements, the yield of Wheat manured by the dung of animals fed on Maize proved as abundant as the crop which followed from manure produced by the feeding of cotton cake, which enriches the excreta with far more nitrogen than that produced by feeding Maize.

The Woburn experiments were instituted by the Royal Agricultural Society, and were placed under the management of its chemist, the late Dr. Voelcker, for the purpose of testing the value of manure obtained by the consumption of different kinds of food and to compare the effects of such manures with those of artificial manures. It is evident that in such a comparison the land to which the various fertilisers were applied should have been of similar quality. But there are other disturbing causes which may vitiate experiments of this kind, and these were not at first generally recognised. The mistake occurred in some rotation experiments, in which the manure derived from cotton cake containing about 40 per cent. of nitrogenous constituents was compared in its results with that obtained from Maize, a cereal containing only 10 per cent. of albuminoids. The results of these experiments were known to the agricultural community before the report of Dr. John Voelcker, who has succeeded his late father as chemist to the Royal Agricultural Society, had been made, and much surprise was expressed that at the close of the second rotation the cotton cake had not shown any decided superiority over the Maize. It has been recently explained in an official report on the "Objects, Plan, and Results of the Woburn Experiments," that this was "probably due to the large amount of unexhausted manure in the land." Before commencing experiments, therefore, on the comparative value of manures the land should be exhausted by repeated scourging crops, as at Rothamsted, where in some cases the deep-rooting Bokara Clover has been grown for the special purpose of reducing the fertility of the soil to *nil*.

It has long since been established that nitrogen is neither absorbed by plants from the atmosphere nor conveyed into the soil to any appreciable extent in any way except by the direct application of manure: still there are some crops which collect nitrogen and leave the surface soil richer than before. Red Clover is usually grown as a preparation for Wheat, and although Clover hay must necessarily withdraw a great deal of plant-food from the soil, it does not prove exhaustive in practice, because the deep and fleshy roots of the plant collect nitrogen from the subsoil and, in their decay, supply it to the growing Wheat crop. Under such circumstances a strong nitrogenous manure may not be required, and may perhaps prove less desirable than a weak manure containing less nitrogen. Enough has been said to show that the field experiments which are now becoming popular, and which are being instituted at many "stations" throughout the country, will require great care and the supervision of managers who possess a competent knowledge both of "practice and science."—H. E. (in *Nature*).

MESSRS. WEBB & SONS' STAND AT THE BIRMINGHAM CATTLE SHOW.—A magnificent trophy of farm and garden produce, grown from Webb's seeds, occupies the centre bay of the gallery, and a finer display could scarcely be imagined. It formed a leading feature of the Show, and the Prince of Wales, who made a careful inspection of it, was pleased to accept a handsomely bound catalogue of Webb's seeds. A choice collection of roots grown on the Royal farms at Sandringham was a great attrac-

tion on this stand. Equally good are all the other exhibits, but space will only allow a reference to the most important. The Imperial or "Great" Swede is to the fore, and the specimens are, as usual, of that marvellous quality which has enabled it to carry off in strong competitions the champion honours in the open class at this Show for fourteen successive years. The Mangolds are also good, including Webb's Champion Globe, Mammoth Long Red, Yellow-Fleshed Tankard, Intermediate, &c. Varieties of common Turnips are also choice, and, as well as the other roots, fully maintain their high-class character, showing the advantages derived from careful selection at the Kinver Seed Farms, said to be the largest in the kingdom. All the popular Potatoes are also shown, as well as several choice new seedlings. Wheats, Barleys, and Oats next claim attention, and their remarkably fine quality is very apparent. Webb's Challenge White Wheat, Kinver Chevalier Barley, Black Oat, White Oat, Kinver Giant Wheat, and Golden Grain Barley have become exceedingly popular. Grass seeds for all soils, of which both purity and growth are guaranteed, are represented by a splendid collection of natural and other grasses grown at the experimental farm. Fine specimens of vegetables were exhibited.

MESSRS. HARRISON AND SONS' ROOT SHOW.—The annual exhibition of roots, &c., grown from seed supplied to customers by Messrs. Harrison and Sons, seed growers and merchants, Market Place, Leicester, took place in the recently added portion to the old premises of the firm, at the latter end of last week. The exhibits consisted of some exceedingly well-grown specimens of Mangold, Cabbage, Potatoes, Seeds, Grasses, and other farm produce. The greater portion of the Show was occupied with the leading varieties of Normanton Globe Mangolds, Defiance Swede Turnips, Champion Ox Cabbage, Giant Red Mangolds, Giant Kohl Rabi, Devonshire Greystone Turnips, Improved Green Barrel Turnips, Potatoes, &c. Amongst the prominent exhibitors were H.R.H. the Prince of Wales, with Mangolds and Swedes grown on the Royal Farm at Sandringham; the County and Borough Asylums; the Corporations of Birmingham and Northampton; T. T. Paget, Esq., M.P.; the Earl of Gainsborough, Exton Park Farm; the Hon. Tyrwhitt Wilson, Keythorpe; Rev. F. Morgan Payler; Mr. J. H. Cooper, Glenfield; Mr. S. Singlehurst, Kington; Mr. T. Mayn, Burton Overy; Mr. J. German, Ashby-de-la-Zouch; Mr. Jos. Wilson, Aylestone; Mr. A. C. Barclay, Scraptoft Hall; Mr. E. L. Driver, Elmsthorpe; Mr. H. R. Parker, The Temple, Rothley; Mr. J. Glover, Kilby Grange; Messrs. Rayns, Barwell; Mr. J. Swinfen, Dunton Bassett; Mr. W. Blastock, Rowley Fields; Mr. W. Everard, Narborough Wood; and other local growers; while specimens were also sent from the counties of Rutland, Lincoln, Warwick, Norfolk, York, Derby, Stafford, and Suffolk. The few Carrots and Parsnips were staged by Mr. Barclay, of Scraptoft; monster Ox Cabbages by Mr. Everard; and highly coloured Red Cabbages by Dr. Higgins. Capital Savoy were contributed by the Prince of Wales and Dr. Finch; some good Intermediate Carrots by Mr. Cooper, of the Albert Inn, Humberstone Road; Onions, Celery, and Potatoes by Mr. T. T. Paget; and a very large Vegetable Marrow by Mr. Swinfen. The new vegetable, named Chou de Burghley—a cross between a Cabbage and a Cauliflower—was exhibited. A number of varieties of Potatoes, including the Magnum Bonum, was forwarded by Mr. Sutton of Birstall, and Mr. Barclay. Messrs. Harrison also exhibited many sorts of tubers grown on their farm, amongst which were specimens of the new English Potato, "The Emperor," described as "an enormous cropper, large, white flesh, late keeper, and disease-resisting." The Show was very numerously attended.—(*Leicester Journal*.)

OUR LETTER BOX.

Foot Rot in Sheep (W. K.).—Sheep affected with footrot should first have the feet carefully washed, all broken parts cut clean off with a sharp knife, and the part affected with rot dressed with Gell's footrot ointment to be had from any chemist. Repeat this twice weekly, remove the sheep to some fresh land or pasture, and you will soon cure them. A ewe is twenty-one weeks in gestation—that is to say, from the time of conception to the birth of the lamb.

REMARKS.

22nd.—Cloudy, with occasional slight showers.
23rd.—Fine, but scarcely any sunshine.
24th.—Very wet; all day.
25th.—Fog in morning; showers in afternoon.
26th.—Dull early; gale and heavy rain from noon.
27th.—Sharp showers about 8 A.M., afterwards fine and warm. Shooting stars very numerous in the evening; about 8 P.M. they were falling at the rate of more than three thousand an hour. This shower was expected, its arrival having been calculated from the data for Biela's comet.
28th.—Gale and heavy rain early; fine day.
Excepting perhaps the middle week of September this is the first week since July in which the temperature has reached its average. It has been a warm, damp, and very rainy week.—G. J. SYMONS.

THE APPLE ON LIGHT SOIL.

MOST observers must have been struck at the extending taste for articles of consumption which, up to a period very close to the present, were confined to a comparatively limited class, but which are now the everyday want of the many. As more particularly peculiar to our own special employment the wonderful development of the taste for the Tomato and the increased consumption of Grapes may be mentioned as well-known instances. The Apple is also attaining a rapidly increasing consumption, especially among the middle classes, but also among the working classes. The fruit imported from the United States and Canada, and the reasonable prices at which that fruit is purchaseable, has doubtless been the chief cause of the Apple becoming necessary in so large a number of homes.

The point which producers have to aim at is to see that a taste which has been created and which will increase year by year has the means of satisfying its demands. There are at the present time sufficient Apple trees in the country to go a long way towards satisfying these demands, but unfortunately the great majority of trees of a productive size are of varieties which are deficient in the size or quality of fruit, often uncertain croppers, and large numbers too old. I do not think I am exaggerating the state of things in private gardens in saying that for every tree of a variety meeting the requirements of a good Apple, there are at least a dozen which are practically valueless. In provincial market gardens the same state of affairs holds, with the result that fruit retailers are obliged to place their orders for foreign grown produce. The remedy for this state of things would be simply to take out the old trees and plant good sorts, but the country is going through a revolution at the present time, which, though quiet, is none the less sure, and the result is that occupiers of market ground are chary about investing in a property which would take a few years to make good their outlay and secure a profit. A grower under three landlords told me the other day that though he fully recognised the future there is for the Apple as a popular market fruit, he was afraid to make any investment until he saw how things would turn, and as a matter of course landowners are equally shy of entering into costly investments.

If ever allotment farming—gardening were the better name—becomes the national undertaking its promoters expect it to be, the cultivation of the Apple must in suitable soils and climates become one of the best paying crops which will be grown, but in order to make it pay sorts alone which have been tested must be planted. In our northern climate there is no Apple which I am acquainted with that will pay to grow for dessert. These are either too uncertain croppers or do not grow large enough. We are, therefore, restricted to culinary sorts, and of these the only certain croppers are kinds which must be used before January. Of course there are plenty of good later kinds which meet the requirements of home use, but size for market is now an all-important

matter. *Mère de Ménage* is the only Apple which I should be inclined to recommend as a later variety which is at once a constant cropper, profitable as to quantity, and the whole of the fruit of a good size. But I am afraid a good climate will be found indispensable for it.

Since I have taken any great interest in the Apple it has happened that the soil in which I have been obliged to study its peculiarities has always been of a "light" character, so that I can only speak of it under that limitation. However, as the constituency of the Journal will include a very large proportion of gardeners similarly situated, the result of that limitation may not be of so much consequence. The main points of general interest which I have found about the Apple on light soils are—first, the necessity of deep cultivation; second, the necessity of good feeding; third, the great influence of stock to the advantage of the Crab or free; and fourth, the necessity of strictly limiting the varieties to those suitable for light soils.

Enlarging on these four points I have found that Apples planted on shallow soil have been unredeemable failures, and that those which have a deep root run 30 inches in depth have succeeded very well. The drought of the past summer, so fatal to the size of fruit in many gardens, has had little or no practical effect in ours, and that more especially where the ground had been lately enriched. Of course it is quite the thing to say in regard to this matter, Keep the roots near the surface; but under ordinary circumstances to keep roots near the surface in the case of soils such as those under consideration is simply to court failure. I have nothing to say against those who have the means of supplying water to the trees in dry weather, dispensing with other than mere surface cultivation, and I may go a step further and admit that fruit grown under such conditions will be better coloured than those which have been grown in a deep soil. But what I want to show is this, that under the circumstances under which gardening is carried on, and in the great majority of gardens, deep cultivation, so that the trees may have a root run away from the effects of local climatal influences, is simply a necessity. I have found also that the roots have no tendency to run out of the cultivated soil when it is cultivated deeply enough. Trees root-pruned seven years ago were this year found to have extended the roots made since then, not downwards, but into the good soil.

This brings us now to the second point—the necessity of good feeding. Deep cultivation does not always insure good feeding. Deep cultivation may improve the soil, aerate the soil, and make it of a kindlier nature, but it will not give the trees any more food—at least, not to an appreciable extent. Feeding material the cultivator must supply. The best material, and at the command of every gardener if he likes to look after it, is decayed garden rubbish. This is easily brought into a fit condition to use. Our plan is to make up a heap annually of about forty loads. This is composed of all the decayed vegetables, ashes from fires, leaves, and the general rubbish constantly accumulating in gardens, and after it has lain twelve months it forms a heap of compost which is of the greatest value. This should be laid on at the rate of from 9 inches to a foot thick and mixed with the soil as the ground is being trenched. When the trees are being planted more may be employed—in fact, too much of it can hardly be made use of. But beyond this a coating of dung is required over the roots of trees annually. When roots are near to the surface it must not be dug in, but where the roots are out of the way digging it in will do no harm. Cow manure is the best to use. I have found the removal of soil from above the roots, and a thick layer from the rubbish-heap compost forked into the soil, work wonderful improvement in the strength and vigour of heavily cropped trees.

Then with regard to the stock. I do not find the least difficulty in producing fruit on small trees on the free stock.

I have had crops on two-year-budded trees, and although such small trees may only bear from two to six fruits, I think it gives to young trees a fruitful cast to allow them to bear from the very beginning. Some sorts, if healthy, invariably form fruit buds on the same growths which bear fruits, and the necessity laid on young trees to provide for the finishing of fruits would appear to cause the formation of a greater number of fibrous roots than would otherwise be the case. In light soils canker is the worst enemy to keep under, and as a rule the Paradise stock makes no headway against canker in light soil. By the simple process of lifting young plants biennially for the first six years of their existence, and shortening back on these any gross-growing roots, the trees may thereafter be left to themselves for several years.

Then as to the sorts to grow. The two Congresses that have been held have helped greatly to show what are the kinds which are most reliable. It does not follow, of course, that we must rest our judgment entirely on what is seen at these exhibitions, but anyone who has had a few years' experience with Apples—that is to say, if he has been interested in his work—is sure to have had some enlightenment on what is one of the least of the accomplishments of the general gardener—a knowledge of Apples. Taking those Apples which are certain croppers, produce fruit of a good size, and the trees healthy and not subject to canker in a harmful degree, I have found the following all that can be desired. I take cooking sorts first. The earliest is Early Julien, grown largely in Scotland as Tam Montgomery, also very often as Juneating. This, as a rule, bears very heavy crops, the tree healthy and not a great grower, and the fruit excellent for cooking, sometimes, as at Edinburgh last September, shown successfully as a dessert kind. Duchess of Oldenburgh also does extremely well with us, making a strong upright growth, and always crops well, though not heavily. Keswick Codlin is still one of our best Apples. On trees which are not too old the fruit is good as to size, and as a cropper it is, of course, first-rate. Lord Suffield we are not increasing, though the stock is not allowed to get down. With us the tree is unhealthy, owing, I imagine, to a tenderness in its constitution. Very often also the fruit is much spotted. The Old English Codlin, erroneously named in many places Dutch Codlin, does extremely well as a large standard tree. As a dwarf it does not crop so well, and we should hesitate to plant it in walled gardens. Nelson's Codlin is very prolific, well worth growing in Scotland. In good seasons, when well ripened, it is good enough for dessert. The fruit keeps well with us till after Christmas.

Ecklinville Seedling all Scotch gardeners look upon as a friend. It is very common, always crops, and the fruit is always of a good size. It does not do well with us on the Paradise but splendidly on the free stock, and though subject to canker, its free habit of growth compensates for any drawback on that account. The shoots, though strong, should not be much shortened back, as these produce fruit buds their entire length, and I find it a very good plan to keep cutting the older branches as they become overcrowded, so that these younger ones may have room to take their places. With us this is a November Apple. Succeeding it as to time of using, but a finer Apple, is Warner's King, a sort of many synonyms. I have seen it as Hawick King, Howick, King of British Apples? Nelson's Glory, Nelson's Victory, Drumlanrig Castle, Barker's Seedling, and Cobbett's Fall, and doubtless many more are attached to it. We have about three dozen bearing trees of this Apple, and find them generally of the healthiest type, though the oldest canker rather badly. Though not a large-growing tree, its growth is very vigorous in a young state. With Lord Derby and Gloria Mundi it divides the honour of being our largest Scotch fruit, and as a rule it is the largest. All the fruit is of a large size. Cox's Pomona, though not of the largest size, is always a good cropper, the fruit handsome, and the tree healthy. We use this variety in December. In good seasons it may be used for dessert.

Stirling Castle is another of those Apples which have earned the gratitude of all gardeners. With us it has one fault—that it fruits so freely as to stop wood growth. The only plan is to feed well and leave as much wood as can be left. We use it in December. Rymer, though it cannot be always depended on to crop, is at the same time too good to be left out. The tree is of a strong spreading habit of growth, and in most seasons is a very heavy cropper. It does best here with the centre of the tree kept well cut out, as also all the older branches and young ones left to take their places. It is in use in January. Following in the season of using comes Kentish Fillbasket, one of our most reliable sorts, though the tree is somewhat subject to canker. Mère de Ménage is one of our best varieties, and does capitally in our light soil, bearing every year, and the fruit always of good size and of a fine colour. The tree is of spreading habit, healthy, and not of a large growth. The fruit is almost without core, and contains more useable material within the skin than any other kind I know. Northern Greening is a very large cropper, and being a rather poor grower requires liberal treatment. The fruit is of medium size, and one of the best cooking sorts. Such well-known varieties as Cellini, Hawthornden, Blenheim Pippin, and Dumelow's Seedling (Wellington) canker so badly as to be worthless. Other kinds, as the Dutch Codlin and Catshead, grow too large for a garden; and many others, as Striped Beefing, Emperor Alexander, and Yorkshire Greening are too shy croppers; Bess Pool is sometimes good, but very uncertain.

Good dessert sorts are not numerous here. Margaret and Irish Peach are the two best earlier sorts. Yellow Ingestrie, often grown under the name of Golden Pippin, is very good. Reinette de Canada is very fine just now. Steward's Seedling, dubbed worthless at the Chiswick Congress, is the most profitable of market Apples. This is the greatest cropping Apple I know, and when ripe very sweet; an October fruit. Cornish Aromatic is also a great cropper, and very good for Scotland. Golden Winter Pearmain, one of the best, but extremely bad with American blight; Adams' Pearmain, a large and certain cropper, which needs a good season; Claygate Pearmain, very good; Cambusnethan, a very good Scottish Apple, Duke of Devonshire, certain and good; Old Scarlet Nonpareil, also very good. Fearn's Pippin and Court Pendu Plat are two of the best late varieties.

We grow many others, but for various reasons I do not name them here. The above are all grown in the open garden, very superior fruit being obtainable from walls, but the fruit is not so well flavoured. I may just add that these are selected from a hundred picked sorts, and we have fifty others under trial, but we in every case depend on a few varieties of which we have a number of trees for our supply of fruit.—B., *East Lothian*.

ALLOTMENT CULTIVATION.

"POLITICS, politics, politics—nothing but politics. I shall be glad

'When the hurlyburly's done,
When the battle's lost or won.'

So that we may all get settled down again to more congenial work. But nobody can shut his eyes to the fact that the present election is destined to bring under allotment cultivation, and consequently horticulture, a vast amount of land which is at present agricultural. Both parties are bidding for votes on these principles, so that throughout the kingdom it must be a great question as regards disposing of the vast amount of extra produce or to find a market at remunerative prices."

Thus writes our correspondent Mr. Hiam in excuse for the delay that has occurred in sending notes on the canker of fruit trees. These notes will be found in another column. Important as that subject may be, the one alluded to above is of far greater moment. There cannot be a doubt that an increase in small allotments of land will follow the late "hurlyburly"—not by "compulsion," but by the far better way of willing concession on the part of proprietors of estates. We know of landowners perfectly ready to grant small plots of ground to cottagers who are able and willing to cultivate them to their own advantage. We should rejoice if every man

who can do that shall have the opportunity afforded him. But it must not be supposed that the mere granting of allotments to every person who has a fancy for a "bit of land" will transform this country into an arcadia. It is not the allotment as such, but the labour and judgment of the man that tills it, that will render its acquisition of value.

In numbers of parishes in the kingdom small allotments of land have been plentiful for generations, and thousands of persons have been benefited thereby; but, on the other hand, the fact must be acknowledged, simply because it cannot be ignored, that in instances innumerable the plots have been of no service to the holders of them, because the land has not been properly tilled and cropped. One man will live where another will starve in this as in other vocations. The industrious and thrifty succeed, the loiterers and the careless fail, and there is unfortunately a considerable percentage of these in every community. It is no secret that many holders of allotments have failed to cultivate them remuneratively, and it is to be feared that these failures have had an influence, perhaps too great an influence, in limiting the granting of land in small plots to the working classes, for it cannot be otherwise than regrettable that the industrious and thrifty should be prevented from investing their labour in land because of the shortcomings of the thoughtless and less enterprising amongst them. It is, however, not at all unlikely that a new start will be made in the letting of land in small parcels at a rent not exceeding that for larger tracts; and well-meant advice will be tendered to the tillers to abandon old notions of growing corn and Potatoes in favour of green vegetables for sale.

It is easy to eliminate strings of figures from "Covent Garden prices" published in the newspapers, which show in an apparently conclusive manner how profitable vegetable culture must be; but such figures by no means represent the amount that can be realised in small isolated plots. It can pay no one to send small consignments of vegetables to London or other large vegetable markets. It were as vain to convey the water supply to great towns in buckets as to send garden produce in dribbles from miniature allotments. What may be termed the garden culture of parcels of land of a rood more or less can only be profitably conducted near towns when the cultivators make arrangements with hotel managers, boarding-schools, or small greengrocers to take the produce as it is ready for gathering. This often answers the purpose of retail vendors, as it prevents the necessity of their going to the wholesale markets for what they require; but even to retain a connection of the kind indicated the supplies must be regular, as greengrocers in towns cannot afford to tell their customers to wait till supplies come in.

In suburban localities small plots of land may be turned to excellent account, not only in growing vegetables, but various kinds of popular hardy flowers, for which there is such a great demand; but it is entirely another matter in the case of allotments in obscure country villages, miles, it may be, even from a small market town, and it is precisely in those thinly inhabited districts that the great increase in small allotments of land will occur. By all means let them be provided where they do not already exist for the benefit of agricultural labourers, whose wages are not likely to increase, and whose prospects are the reverse of cheering; but let not the men be misled by the golden dreams of kind-hearted persons who are haunted by Covent Garden prices for vegetables, and think these can be obtained at any time and anywhere where garden produce is grown.

Those prices have no application whatever to small allotments in sparsely populated districts, and if a large number of these are induced to rely on small patches of different kinds of vegetables that spoil in a week if not sold, the "great question" indicated by Mr. Hiam will assuredly arise as to "finding markets for the disposal of the produce at remunerative prices." That is a very practical view, the very kernel of the question of growing vegetables for sale in what can only be accurately described as infinitesimal quantities in a number of miniature plots far from the busy haunts of men. Green vegetables can only be profitably sent to distant markets in large quantities, and then the districts must be favourable both as regards soil and convenience of quick transit at cheap rates by truckloads. Even under those conditions loss has often to be endured as a check to profits on more fortunate consignments.

It has further to be remembered that in many if not in most districts the vegetable supply of provincial towns is largely contributed by private gardens, not a few of which are to all intents and purposes market gardens, and inexperienced cultivators of plots in open fields, where the land is less rich, cannot possibly compete successfully with those specially favoured purveyors. Platform doctrines and newspaper lectures on profitable vegetable culture by small allotment holders on country farms are founded on insufficient evidence; and if they should lead to anything like a general adop-

tion of the practice that is made to appear so advantageous, while a few persons may by chance be slightly benefited, immeasurably the greater number, who cannot afford to make experiments, will assuredly be disappointed.

This is written with an earnest desire to see the condition of a large section of the community improved. Allotments of land a rood more or less in extent would be of great service to numbers of men who would gladly labour to render them productive. If they can see their way to grow green vegetables profitably for local consumption they will of course grow them, but we are convinced they will make what will be to them a costly mistake if they crowd their ground with vegetables of a perishable nature for supplying distant markets. What we have said will not reach in a direct manner the humble tillers of the soil we would hope to guide; but we have the ear of a great constituency who have the disposal of land for allotment purposes, and to them we appeal, also to practical gardeners who can advise soundly on this matter, not to encourage hopes that cannot be realised in the great multiplication of patchwork market gardens as a panacea for all the inconveniences attending "short time" and a falling wage rate.

The demands of the Education Act compel hard-working struggling men to make a present sacrifice that is hard to bear in consideration of future benefits that may accrue to their families. They are deprived of sums that may appear small, but which are really considerable that once were earned, and as some sort of compensation would be afforded by the granting of small plots of lands to be tilled well and cropped in the good old country fashion of growing vegetables for their families and corn and roots for the poor man's best friend—the pig that pays the rent, with another or two for garnishing his cottage walls. A rood of land well tilled will grow a quarter of corn, which will pay the rent of the land and leave a margin besides the indispensable straw for the comforts of the "friends" and for conversion into manure. Another rood will grow from 1½ to 2 tons of Potatoes, and these if sold would be profitable, but the bulk can be turned to better account at home. The labour attending culture of this kind is mainly that of evening hours and odd days, or a week now and then, when through slackness of work men would be otherwise perforce spending their time uselessly and vowing vengeance against the powers that be. A thrifty and contented peasantry is the backbone of a nation's strength. We are glad to observe a marked disposition exists to help those who are willing to help themselves in cultivating small plots of land in addition to their daily labour—not starvation 5-acre farms instead of it. We could indicate a whole district of these, but the failures have been so many and the privations so great that the proprietors now prudently and, it may be added, mercifully, refuse to let the plots except to persons who have some trade or occupation mainly to rely on as a means of livelihood. With employment more or less regular to rely on, and plots of land in addition for the investment of spare time, it would be the fault of the men if they did not improve their condition and be more contented in their homes. But the secret of success is high culture—clean land and well-supported crops. There is no other safe course to pursue, and those who fall into a loose and slovenly method, and by their neglect grow weeds instead of food, should be given to understand they must give up the land to others who prove themselves worthy and able to manage it well.

This naturally leads to the consideration of another aspect of the question. It has hitherto been the rule with but few exceptions to limit the extent of allotments to individuals regardless of the manner in which the ground is cultivated. We fail to see that this is a sound principle whether regarded from the landlord's or tenant's point of view. The limit is a rood or half an acre, or whatever the extent may be, and however well one person cultivates his plot, he must have no more, while his slovenly neighbour does no good for himself and spoils the land of the owner is permitted to have just as much. This is not the principle on which land is let in larger quantities. If a farmer cultivates 100 acres distinctly better than his neighbour does an opportunity is found for increasing the holding of the former. The man who renders his land the most productive, and is ready with his rent, is very properly encouraged. But there is no corresponding incentive given to the allotment holder. It is evident to all practical men who are acquainted with a series of plots that one man is far better capable of cultivating three portions than another is of managing one. Why, then, should not he who shows his capacity be recognised and have the encouragement that is due to strenuous endeavour and proved worth? If allotments were governed on that principle every striving man would have something to hope for and work for—an incentive for his energy—and when it was seen that he profited by his labour his example would be a stimulus to others who are now content to lag behind and soothe themselves by the ready excuse of "it's no use trying." As they have nothing to gain they

take care to have little to lose. But let a thoroughly able and industrious man feel he has something to gain by the steady increase of his holding, and let others see that he gains by his efforts, and the whole aspect of things would be changed. At the present time the best men are crippled in their endeavours to improve the land and their own condition, while the indolent enjoy equal privileges to which they have no fair claim.

In schools, colleges, universities, in trades and professions encouragement is given to develop the faculties of the students, and rewards are offered for progress achieved. Everything that is possible is done to incite to greater attainments, but in allotment cultivation bad and good managers have the same privileges by the rigid limitation system that now prevails, and which appears to be at variance with the sound principles that govern commercial and even agricultural life in connection with large holdings. But whether a change is instituted of the kind suggested or not—and it is almost certain there will be sooner or later—our more immediate object is to point out the extreme improbability of a great increase in vegetable culture in small patches in agricultural districts proving anything like remunerative to the tillers as first-rate crops of roots and corn for the sustenance of their families. Fruit can and should be profitably grown in home plots, but cannot be regarded as certain to be satisfactory in mixed plots in open fields where birds and boys would need and obtain a share of the crops.

NEW PRIMULAS.

THOSE specially interested in Primroses will no doubt be pleased to learn that important additions are still being made to the host of those named and described, whether in cultivation in our gardens or not. It is only a year or two since Dr. Watt described a large number of new Himalayan Primulas in the Journal of the Linnean Society. The descriptions are fortunately accompanied in this case with careful botanical drawings, and which greatly assist in giving an idea of their horticultural value. Since that time a few of the new species have found their way into cultivation, but in my opinion, seeing the almost everyday communication between this country and the colonies, it is regrettable that a still greater number should not have found their way across the water. As represented in the drawings, *P. Elwesiana*, notably *P. Dickeana*, *P. Kingii*, *P. Wattii*, and others have all large showy flowers, apparently quite distinct from anything hitherto in cultivation, while *P. soldanelloides*, *P. sapphirina*, *P. reptans*, *P. muscoides*, and its variety *tenuiloba*, *P. Hookeri*, and others are little gems; and while the former group may be placed in the locality of *P. Stuarti* and *sikkimensis*, the latter are represented in cultivation only by *P. Hydei* and *P. minutissima*. Then later still we have *P. Reedii*, found, we believe, by Mr. Duthie in the Kumoan district, a very distinct species with large pretty white or cream flowers. And later still, indeed only last year, a colony containing no less than sixteen species and a variety has been found in or near Yun-nan, a district or province of the great Celestial Empire bearing that name. It is situated near to Burmah on the one hand, bordering Tibet on the other, and for all practical purposes may be designated as almost a continuation of the great range of Himalayan Mountains. As would naturally be expected, the differences between the new species and the old Himalayan ones, with many of which we are well acquainted in cultivation, is but little, and it is not at all improbable that some of them will be reduced to varieties of these standard species if we may judge from the very broad views which some of our English botanists take of a large number of the most popular genera at present in gardens.

The plants were gathered by M. Delavay, a missionary travelling in those parts, in the early part of last year, and were fully described by M. A. Franchet of the Paris Museum in the Bulletin of the Botanic Society of France for November.

All the species, with two exceptions, belong to the section *Aleuritia*—i.e., *P. septemloba*, M. A. Franchet, which belongs to the section *Primulastrum*, and *P. Delavayi*, M. A. Franchet, for which a new sub-genus has been coined called *Omphalogramma*. *Primula septemloba*, nov. sp., nearly allied to *P. mollis* and *P. geraniifolia*; it seems, however, a good species; *P. bullata*, nov. sp.; *P. bracteata*, nov. sp.; *P. sonchifolia*, nov. sp., closely allied to *P. obtusifolia*, but having distinct leaves resembling those of *Sonchus asper*; *P. serratifolia*, nov. sp. This name seems unfortunate, seeing that it is already a synonym of *P. marginata*, and which was taken up and used by Gusmus for a cross between *minima* and another. It is also allied to *obtusifolia*. *P. secundiflora*, nov. sp., resembling *P. sikkimensis*; *P. calliantha*, nov. sp., allied to the above; *P. amethystina*, nov. sp., with foliage like *Bellis perennis* and flowers resembling those of *P. Kingii*; *P. bella*, nov. sp., allied to *uniflora*, but with different leaves; *P. yunnanensis*, nov. sp., allied to the above; *P. spicata*, nov. sp., a remarkable species different from all other Primulas in having a

spicate inflorescence, quite a novelty, the flowers being much larger than *P. uniflora*; *P. glacialis*, nov. sp., allied to *P. nivalis* and *P. Fedtschenkoi*, both Turkestan species; *P. dryadifolia*, nov. sp., resembling *Dryas octopetala*, the leaves and bracts giving it a distinct character; *P. pinnatifida*, nov. sp., allied to *P. Wattii*, flowers resembling *Erinus alpinus*, but very much larger; *P. cernua*, nov. sp., near to *P. capitata*; *P. Delavayi*, nov. sp., sub-genera *Omphalogramma*; *P. auriculata* var. *polypphylla*, which is very remarkable as being a Siberian species, and also three Himalayan species—namely, *P. denticulata*, *P. Stuarti*, on Mount Che-tcho-tza, &c., and *P. sikkimensis*, on the glaciers of Li-kiang.—M.

A CONTRIBUTION TO THE STUDY OF TRANSPIRATION UNDER THE DIFFERENT RAYS OF THE SOLAR SPECTRUM.

A PAPER on the above subject by Rev. Professor Henslow was read at the Linnean Society on Thursday last, December 3rd. The experiments described were undertaken to test the results of Wiesner, who found (contrary to the opinion of others, who thought that the brightest rays of the spectrum were the chief cause of transpiration) that it was mainly due to the rays which are absorbed by chlorophyll. The spectrum of that substance reveals seven absorption bands, the most powerful of which are in the red, blue, and violet, and when plants were grown under coloured glasses Mr. Henslow found just as Wiesner had done, that transpiration attains to a maximum under the monochromatic red glass and under the blue and violet as well, while ordinary colourless glass gave another maximum. On the other hand yellow and green gave a minimum.

Wiesner's interpretation is that light thus absorbed by chlorophyll is converted into heat, and then it raises the temperature of the tissues, and so causes the formation of aqueous vapour. If this be true it would seem to account for Dehérain's discovery that plants can transpire in a saturated atmosphere, and as a corroboration Wiesner found that light which had been first transmitted through a solution of chlorophyll was almost powerless to cause transpiration. A fact which Mr. Henslow could not account for was that while the red glass which admitted no other rays gave a maximum, the yellow glass, which transmitted red and green rays besides yellow, gave a minimum. It would seem as if yellow had actually a retarding effect upon the other rays.

The method adopted by Mr. Henslow was to grow small Lettuces and other plants in miniature pots, and by wrapping them up in a gutta-percha sheeting tied round the base of the stems all loss of moisture from the earth was prevented. Then he weighed the whole day by day after its having been under each coloured glass for twenty-four hours in succession. He thus ascertained the per-centages of the losses, the means of which gave the results mentioned above.

Mr. Henslow also drew attention to the importance of distinguishing between transpiration and evaporation, the former being a vital action, the latter purely physical, and will take place from dead and living substances, but is modified or held in check to some extent by the latter. Thus if a leaf be cut in two, and one half suddenly killed by scalding, it will be found that this one rapidly dries up, while the other loses water much more slowly. Again, thick leaves and older ones absorb more heat than thin ones and younger ones respectively, yet the transpiration is greater from young leaves and deciduous, contrary to what one would expect if transpiration depended solely upon heat.

LADY BEATRICE LAMBTON PINE APPLE.

THIS fine Pine Apple has now been a long time before the public; yet we seldom hear of it being exhibited at any of our shows. This is much to be regretted, as it is a noble-looking fruit and reckoned of superior flavour. It has, in my experience, however, one fault, which may account for its being so little heard of—viz., its liability to get discoloured at the base, the juice oozing out as the pips ripen. It is of a very juicy nature, and large fruits are most liable to go bad in this way, which detracts from their appearance and prevents their appearing upon the exhibition table. No doubt, like some of our best varieties of Grapes, this Pine requires some special treatment. My endeavour to find such is the object of writing these lines. If any of your readers have known and overcome this evil, by giving their mode of treatment through the Journal they will do good service to many besides myself.—D. B.

ICE HEAPS.

I HAVE somewhere seen an account and figure of storing ice in the form of a thatch-covered heap, and shall be glad to be directed how to proceed in keeping ice in some such way as suggested. Our ice-house is not large, and we wish a supplementary store for use early in the season,

so that the house can be kept closed as long as possible.—E. G., *Derbyshire*.

[The following method of storing ice was adopted by Mr. Perkins at Thornham Hall :—

We always, if sufficient ice can be secured, make a large stack independently of the ice-house.

To insure a stack of ice lasting a considerable time, we put on two layers of thatch, the first on the ice, and the other on a rough framework made of fir poles and slabs, as in the accompanying engraving. It takes about thirteen poles for the inside and a like number on the outside. On the latter thin slabs are placed in a horizontal direction, on which the outer thatch is placed. To keep the outside poles a sufficient distance from the inner ones, short pieces of wood, about 9 inches or a foot long, are fastened between them. The body of air between the two coats of thatch contributes greatly towards the safe keeping of the ice.

We generally have to put new ice on the top of the old in the ice-house, all of which is snugly covered with straw. Now, it is an old saying that we should let well alone—that is, in this case, if sufficient ice is pre-

Fig. 76.

served for the family, why trouble about any fresh plan? and we feel afraid to try any other method, fearing success might not attend our efforts; but I must confess I am not particularly fond of straw, and if it is not indispensable, a much greater quantity of ice could be stored in any house, and the ice would be saved from the pernicious effects arising from its being surrounded with wet straw, which could be saved for a more appropriate use. If some of the great ice-preservers in this country would state their opinions as to whether ice can be preserved without straw it would be a great boon to many.]

SHOWING LATE GRAPES—MIXED VINERIES.

BEFORE taking final leave of the subject of Grape showing and Grape judging, I purposely waited to note the result of the competitions for the prizes in the Grape classes provided at various Chrysanthemum shows, and also the success of one very frequent exhibitor at the August shows held in this district. If the latter had repeated any of his former successes this season I should have had to modify some of my opinions which have found their way into the *Journal of Horticulture*, as well as others I have not been backward in giving expression to whenever the opportunity offered. It will be remembered that one of my objections to the growing practice of exhibiting late Grapes at early shows, is the fact that by encouraging it we really indirectly injure both the exhibitor and the exhibitions we all profess to have such a regard for. Several practical gardeners commented on my remarks, and for once I had a following, gaining the support even of one young exhibitor, who out of all my numerous articles found he could only agree with my opinions in this one matter. For this I am naturally grateful and somewhat elated, as it may be the turning point in my career. But seriously, and at the same time I am bound to admit that my opponents made out a strong case against me, and all will agree that there is much to be said for and against early exhibitions of late Grapes.

I am still of opinion, however, that August is too early for these easily coloured showy Grapes to take precedence over well-grown if less showy examples of better flavoured and fully ripe sorts; neither should they be given first honours early in September if unripe, unless indeed nothing is said in the schedule about all fruit shown being fit for the table. Where the latter condition is insisted on, those who do not comply with them ought not to be encouraged at the expense of those who do, any more than they are when they happen, unfortunately, to include an unripe dish of Peaches or other choice fruit in a collection. Would "S." or any other good judge of fruit, give a first prize to an unripe Pine Apple or Melon, especially if there were fairly good ripe fruit

in competition? I venture to think they would not, and why should not this rule apply to unripe Grapes? This brings me to the second portion of my heading—viz., mixed vineries. A gardener, whom my remarks will not affect, has as his main object, and with the full approval of his employer, gaining as many prizes for fruit as possible. Most probably he competes at six or more shows held in his neighbourhood from the middle to the end of August, and on the whole with marked success. All his Grapes for collections of fruit and single dishes are grown in two large well-built vineries, and in each house there are an extraordinary mixture of sorts, these including Black Hamburgh, Madresfield Court, Black Alicante, Gros Colman, Mrs. Pince, Muscat of Alexandria, Buckland Sweetwater, Waltham Cross, and others on trial. The early sorts are turned out of the houses, and not reintroduced till the late sorts are showing bunches, and even more advanced in some cases. In this manner he is able to start forcing early in the year, and yet have the early-ripening sorts not too far gone in August. As may be expected, the Black Hamburgh are never very good, but he is able to take prizes with his Alicantes especially by the middle of August, and it may be the result is perfectly satisfactory to all concerned. But now comes the other side of the question. In his immediate neighbourhood he has recently had an opportunity of distinguishing himself in fruit classes provided at the Chrysanthemum shows, but he was simply nowhere, and probably by Christmas will not have a plump Grape on the place. This is certainly an exceptional case, but what is to prevent others following the bad example, and that, too, without the approval of their employers? I maintain that the addition of numerous Grape classes, and especially those that encourage the early ripening of late sorts, to the prize lists of summer shows will eventually re-act to the prejudice rather than the benefit of those societies in the habit of doing so, and this I assert, not as an enemy, but as a well-wisher of all. The Grape classes are very attractive at all times, but there is always plenty of variety at these summer shows, and some of the Grapes could well be spared.

As a rule the Chrysanthemum shows are arranged by the same committees as manage the summer shows, and in this case what is to prevent the reduction of Grape classes in the latter and insert them in the former? In any case something of the sort will have to be done, as there is a great sameness in Chrysanthemum shows, and those not deeply interested in the latter popular flower must have additional attractions provided, or the "gate money" will most probably soon show a decided falling off. By devoting rather more money for Grapes, and rather less, if need be, for Chrysanthemums, an attractive feature is at once added to the show, this also affording an undeniably healthy stimulus to the culture of late Grapes. Now is the time for this idea to be acted upon, and those committeemen who agree with me in the matter should bring the subject to the front at the next general meeting.

It has been hinted more than once that it is necessary to offer high prizes to attract a good show of late Grapes, and it may be there is some truth in it; but this does not apply to the exhibitions held in this neighbourhood, neither will it long do so at those of other and more recently started societies. At Bath, Bristol, and Yeovil the show of Grapes was good, the competition being close and good in nearly every class, though it must be added that at the first and last places the quality was not quite so high-class as might have been expected, the best bunches very probably having found their way to the summer shows. At Bristol there were about eight classes for Grapes, and a very fine lot of bunches were staged, the sorts including Black Hamburgh, Muscat of Alexandria, Buckland Sweetwater, Alicante, Lady Downe's, Gros Colman, and Mrs. Pearson. The prizes are not high, but they have been long annually offered, and the gardeners in the neighbourhood "lay themselves out" to win them. The same thing would happen in other places with only very slight encouragement and much good be done. Late Grapes cut for summer and early September shows do not keep well, but those taken to the Chrysanthemum shows may be either sold at a fairly good price or taken home again and bottled. Alicantes that we exhibited in a collection of fruit at Bath are now as fresh and plump as others left at home, and I believe will keep quite as long.

I have yet another grievance. Why do so many societies insist upon the rule that a dish of Grapes should consist of three bunches, or why ask for three bunches in the "single dish" classes? Two bunches are ample at all times, and if this number only were asked for much good would follow, and many a gardener in a small place would have a better chance of competing with their more fortunate contemporaries in larger places without appearing to strip a house for one show. The fact is, the "gate money" is unfortunately the all-important factor in the business, and the framers of schedules too often totally disregard all remonstrances from those who well know that the producing an imposing effect in a tent does act prejudicially on those whose lot it is to do it. The Royal Horticultural Society has set a good example in not asking for more than two bunches, and I am glad to see they have followed it at Bristol. All societies should stipulate for a limited number of any kind of fruit, or only sufficient to form a small dish, and it would be fairer and better for all concerned. A wise choice of judges would then complete the reform, and frequent just causes for grumbling be removed.—W. IGGULDEN.

HELLEBORUS NIGER MAXIMUS.

ALTHOUGH we have a number of herbaceous plants there is none that may now be termed gay; indeed, the only exception is that of the Giant Christmas Rose, which I had under the name of *Helleborus niger maximus*, and which, I think, is not different from that sent out as *H. niger altifolius*. It is certainly a most desirable plant, being the first with us to flower,

forming a clump about 2 feet across, and this in three seasons' growth. The flowerstalks rise to a height of 12 to 18 inches, heavily tinged with purple, and bear one to three flowers on each, which in the bud state are extremely chaste and beautiful, of a pale pink or blush, the flowers white inside when expanded and rose outside. The flowers are very large when fully expanded, sometimes nearly 6 inches across, and very persistent. The leaves are large, deep or purple-green, the footstalks purple and mottled, and of great substance, being thick and leathery. It certainly ought to be in every garden, as also the lesser, but equally floriferous, *H. niger angustifolius*.

Snowdrops, Winter Aconites, and Crocuses are well above ground; even Daffodils are peeping, and Snowflakes are high above ground, so that we shall not be long ere we are again gladdened by the harbingers of spring, as we are by the Hellebors before the winter has well set in. The Lily of the Valley—like flowers of the Arbutuses and the Laurustinus, are also beautiful.—A.

WHITE PLUME CELERY.

My thanks are due to "Kitchen Gardener" and Mr. R. Gilchrist for obligingly answering my question respecting the above. Judging from the acknowledgment made by "Kitchen Gardener" and the information supplied by Mr. Gilchrist, it is evident White Plume can only be described as a fine-weather Celery and totally unsuited for winter use. True, as "Kitchen Gardener" says, Celery is wanted from September to Christmas; but in this part of Yorkshire during the past eight years we have had as much as 20° of frost and 2 feet of snow on the ground before the 6th of December. It is against such winters as these we must guard, and not those that do not set in until the advent of the new year.

Most vegetable novelties find their level upon horticultural exhibition tables. During the last autumn it was my privilege to examine and pass judgment upon some scores of Celery exhibits, but not once have I seen a sample of White Plume placed in competition with other sorts. "Kitchen Gardener" admits that it is inferior to others for salading purposes, therefore its cultivation must be upon a limited scale. I thank him for the offer of a pinch of seed. If it is his own growing I will with pleasure accept the same, but if it has to be purchased for me I must beg to decline.

We have to keep up a constant supply of Celery for salading purposes from June until April. Hitherto our Alpha and Omega has been Sandringham White as supplied by Messrs. Veitch & Sons. If anyone can name a better sort the information will be gratefully received by—J. MCINDOE.

NOTES ON CHRYSANTHEMUMS.

CHRYSANTHEMUM CULLINGFORDI.—Seeing several notices in your Journal respecting the present controversy as to whether this is to be classed as Japanese or reflexed, I am strongly in favour of the former, in support of which I wish to draw attention to the fact that it so much resembles *Père Delaux* as to leaf, habit of plant, the size and colour of bloom, that we are led to imagine that if one is Japanese then assuredly so is the other. In fact, I imagine it is a seedling from *Père Delaux*. I have some thirty *Cullingfordi* in 9-inch pots. The foliage and habit of the plants is all that can be wished for, but the blooms, I think are too late, as I fail to see the remarkably brilliant colour they are said to have.—F. C. BARKER.

CULLINGFORDI.—In reference to my notes (page 493) on the variety *Cullingfordi*, in case there should be any misapprehension on the subject, I should like to state that at the time the committee meeting of the Kingston Chrysanthemum Society was held, when the decision was arrived at to recognise the above as a Japanese variety, they were not aware that the National Chrysanthemum Society had also held a meeting the day previous, at which the same subject was discussed and an adverse determination arrived at. Not that it would have influenced the Kingston Committee, as the decision was arrived at almost unanimously after considering the whole merits of the variety as it was known to them. But I should not have asked for your opinion on the subject, nor could I have expected you to give it, in view of the perplexities of the case, had I been cognisant of the above. I merely sent the two varieties to show what we considered a typical reflexed in *Sulphur Gem*, which is truly described as of the *Annie Salter* type, and how the above variety is far removed from it when fully expanded, however the young flowers may favour the reflexed type. The Japanese are so mixed by intercrossing that it takes two or three years' cultivation to get at their true characteristics. I have been asked by many how it was the variety was not awarded a certificate at the Crystal Palace as well as at Kingston, having exhibited it at both places, hence my reference to it in my last note.—C. ORCHARD.

JUDGING CHRYSANTHEMUMS.—In reference to the recent notes on judging the judges, I would mention an instance that calls for comment at the recent Chrysanthemum Show at Bristol—viz., in the principal class for cut blooms, twenty-four distinct varieties, the first prize being awarded to a stand containing blooms labelled *Empress of India* and Mr. Cunningham, which are generally known to be synonymous; and although the judges, when appealed to, admitted that they were identical, they nevertheless by some inexplicable reason failed to disqualify on that account. But the extraordinary part of the matter is, that although the National Chrysanthemum Society's certificate was offered for twenty-four distinct varieties, it was awarded to an exhibit that contained blooms which members of that Society do not consider distinct. If such inconsistent

proceedings are allowed to occur, I fear for the interests of the Society that employs such judges to perform that operation which is of the most vital importance in regard to the welfare of any Society. I call attention to this instance in the hope of inducing some such arrangement being made in the Chrysanthemum schedules as in the Rose schedules, in which a list is inserted, and those varieties which on the authority of the National Society are identical being bracketed together.—M. C.

FRUIT AND PLANT HOUSES.

(Continued from page 488.)

VENTILATION is very important in the cultivation of fruit, flowers, and plants. To keep a house closed from autumn to spring says nothing for the non-ventilation theory, as it is in the winter season when growth is most sluggish. But try the non-ventilation system in a house where forcing operations are carried on, as that of a Peach house or vinery, and in another change the atmosphere at least once a day by careful and judicious ventilation in the early part of the day if possible, contrasting the results with those of the former. The atmosphere is being continually changed by the crevices in the woodwork and laps of the glass, some may say, which I readily grant it is in only too many cases to the discredit of the builder. I believe fresh air to be as necessary for vegetable as it is for animal life, but draughts, heats, and chills are similarly injurious to health, differing only in intensity.

It cannot be too strongly insisted upon that all horticultural structures must be impervious to wet, resisting the influence of cold air, and the escape of warm air. The prevention of heat radiation has been sought in two ways. First, by double glazing, of which I have no experience, and only know that its advocates have long been silent respecting it. Besides, in double glazing we get a vacuum, the most effective of non-conductors, so if we prevent radiation outwards we stop the passage of heat inwards. Second, the best preventive of radiation is what we use for shading—non-conducting.

The theory of ventilation rests upon the fact that heated air rises to the upper portion of a house, and when a sash is opened in the roof the warm vitiated air rushes out, and the cold fresh air comes in. This is sufficient to cause what we term a circulation of air, and produces evaporation, prompting the elaboration of the sap, which the horticulturist is so anxious to have effected as much as possible under the influence of sun or light. If the current is strong the evaporation will be in proportion and excessive; the consequence is a check, which may also be induced by a sudden rush or influx of cold air stagnating the sap. The object of ventilation is to aid vegetation in the elaboration and assimilation of the sap, to give solidity to the wood and foliage, to perfect parts essential to the production of flowers and fruits, which it can never do when kept in a close atmosphere, and equally disastrous is a sudden cooling of the atmosphere. Therefore, whilst we want means to let out the heated air or prevent its accumulation at a certain point in excess of other parts of the structure, we need means to prevent the ingress of cold, to secure a circulation, a change of air of a bracing rather than chilling description. If anything were better contrived to secure a chill I know not what it is, unless it be the opening of both top and front ventilators at once, so as to produce a thorough draught, than the system that obtains of ventilating by the top lights raised by crank and lever movement—an aperture the whole length of the house. True they are on the south side of the house, the warmest, and be it said the point from which the wind most prevails, so that if we let out the heat on that side we certainly have the cold driven in most frequently, it coming in gusts through the aperture that injures or cripples the foliage in a serious and often fatal manner. Ventilators so contrived that the air entering falls directly upon the plants or foliage is not true ventilation. When hot air is let out its displacement must be effected in the gentlest and most subtle manner, for effecting which various expedients have been resorted to, such as passages made in the back walls of vineries, which, whilst allowing the hot air to pass out, would prevent the ingress of cold in a ruinous degree, and which unfortunately are obsolete. There are few contrivances in these days to prevent chills such as were frequent in all our old vineries both at the back or upper part of the house, and also in front, so that the air would pass over the surface of the heating medium, and be considerably modified before mingling with the general atmosphere or acting on the plant foliage.

We have sliding lights, every other opening at top—if a span on both sides alternately, and similar provision at the front or sides. This is much better than raising the lights by crank and lever movement, which is only making an opening or passage for the wind to be driven in proportionate to its velocity. It is a ready means of ventilation, and available even when the weather is wet, yet it is the worst form conceivable, albeit its fault may be considerably reduced by having the ventilation on both sides of the

apex of span, so that the wind will pass clear through instead of being directed into the house, as is the case when the opening is all on one side, and it then acts similarly to a lantern ventilation, which in my opinion is the best of all. This lantern system allows of the hot vitiated air escaping without danger of an inrush of cold, as in a wind it can blow clean through it, as there is nothing to divert it from its course, having in this respect a great advantage over the sliding light, which allows the cold air to be driven directly upon the foliage, the back wall in a lean-to directing it inwards, and similarly in a span when the openings are on alternate lights on opposite sides of the house.

I have reserved alluding to the front or side ventilation, as I only resort to it as most do through sheer necessity, or, in other words, as a means of preventing the temperature rising too high. It seems to me that whatever ventilation we have should be by the upper part of the roof only, or where the heat accumulates in a degree unduly affecting the inmates, which surely could be effected by increasing the provision for top ventilation, and if necessary removing the roof lights. That side light ventilation is needed under our present system I readily grant, and that it is useful with the present system of arranging the pipes in front or along the sides of the house is not to be gainsaid, especially when the air admitted is made to pass over the heated surface and reach the plants beneath them, or passing gently to them in a considerably modified form to what it enters, which is a very different thing to admitting it directly upon the plants. Some have gone to the extent of having no top ventilation, having it solely at the sides, as was the case with orchard houses of the original type, and which are fast becoming as obsolete as the system of culture which called them into existence. A current of air passing through a house is the best possible means of promoting evaporation, of hardening and ripening, and of inducing attacks of red spider—the most baneful of all insects the horticulturist has to contend with under glass.

Whatever the system of ventilation adopted, it should be of such a kind as to allow of a change of air without a depression of temperature, and it should also be ample so as to prevent the temperature rising too high for the successful culture of whatever fruit or plant the structure may be devoted, and it ought to be perfectly under control. I am convinced that a perfect system of ventilation is to be found in the direction of moveable roof-lights, commencing at the apex and downwards by degrees as practice finds expedient until the whole is withdrawn, and which gives me an opportunity of again referring to the advisability of having the roof-lights of all fruit-forcing houses moveable, so that they can be withdrawn at the will of the cultivator.—G. ABBEY.

(To be continued.)

GLADIOLUS COLVILLI ALBA.

AMONG hardy bulbous plants I know of none that can compare with this in general usefulness. As a permanent pot plant it is unequalled, and its chaste and elegant pure white blossoms make it a fit companion for even the choicest exotic flowers; indeed, it must ere long be among the indispensables in all floral arrangements. It is one of those plants which, owing to its erect habit, occupies but little room in the forcing department, and from which a maximum amount of flowers may be obtained in a minimum of space, a fact which should have some weight with those who grow cut flowers in quantity, and especially so where space is limited. Unlike the family to which it belongs, it will if established in pots withstand forcing with impunity, which considerably increases its value as a pot plant. Among a few nurserymen who grow cut flowers in quantity it is well known and appreciated. Not so, however, with gardeners generally, as comparatively few seem to know little or nothing respecting it. This season I have grown a quantity in pots, and they have elicited the admiration of all who have seen them. It is of extremely easy culture, which is another point favouring its extensive cultivation. It may be that it is not grown so extensively or so frequently met with as its merits entitle it to be from its being regarded in the light of *Gladiolus* generally which are not hardy. With this, however, the case is different, since both the typical plant and the variety now under notice is perfectly hardy—that is, if withstanding 22° of frost without injury may be considered such. And not only is there this distinction in its complete hardiness, for it is nearly evergreen, and is more or less active all the year round if allowed to remain undisturbed in the open ground. When this fact is fully realised we shall see it grown in quantity, and those who once take it in hand will not lightly throw it aside. It may be well here to remind those who would give this lovely plant a trial, that if ordered early it can be supplied with Dutch and other bulbs. It must

not, however, be left to order with the hybrids of *Gandavensis*, for it is possible to have *Colvilli* and its forms in flower almost before the ground is fit for planting outside the general collection.

A word of warning by the way. I have been extolling somewhat high a plant of sterling merit, and without this word of warning those unacquainted with it may on first receiving it be disappointed with it. Its corms are about equal in size to those of a good-sized *Crocus*, which is so different from the forms of *Gandavensis* that it has caused many to regard it as mere rubbish, and I know instances where those receiving it for the first time never expected flowering plants. It differs again in another and important particular, hence the floriferousness which so characterises it. Instead of one break issuing from these comparatively small corms, it is not unfrequent for it to throw up from three to six, depending of course on their individual strength, and seldom less than three, each of which bears a spike with from six to ten of its satiny white blossoms, elegant in the extreme.

As it was intended to keep a good number in pots, the whole of our stock in pots were shifted into larger ones when making free growth, so as to give increased strength to the new corms. When these had finished flowering and growth matured they were placed in a warm sunny position to ripen. Towards the middle or end of October a portion was introduced into slight heat, as I am inclined to believe that the earliest of this year may be had in flower with a little management and without any undue forcing from Christmas onwards. With frame culture and slight warmth it will, if potted early, flower for Easter, and when established in pots and introduced in slight warmth during October it may, I think, be had at a time when such plants are of great value. Strangely enough the majority of our white midwinter flowers are plants of extreme hardiness, and whose natural flowering comes with late spring or early summer, and if in the charming plant under notice another may be added so much the better.

For pot culture use one-half rich loam, to which add leaf soil and peat in equal parts, making the whole rather sandy. It delights in a free, rich, open soil, and should never be planted in cold, heavy, or retentive soils, for in these the results will be anything but satisfactory. Place four corms in a 5 inch pot, and if the flowers are not required for cutting the plants will form an attractive featuredotted here and there among the occupants of the conservatory. In the open ground it flowers from July to the end of August, and if various situations are chosen for its flowering season outdoors may be somewhat lengthened. Some of those grown in pots this season for indoor decoration might with advantage be planted in the hardy herbaceous or mixed border, a sunny and warm border always preferred. Plant it from 3 to 4 inches deep, and if the weather be very severe it will be helpful to it to mulch the ground with short stable manure or spent hops. Its rapid increase, too, is worthy of note when under good cultivation, for it will double and even triple itself in a season, and if allowed to remain in the ground undisturbed for three years the crop will be a surprising one. Some considerable experience with this lovely plant in the open ground and in pots has convinced me that it is one of the most valuable of hardy bulbous plants. For growing in the open border plant in early autumn. They need but little room for development and where space is limited may be planted *en masse*. With the existing facilities of the parcel's post a hundred or so may be transmitted.—J. H. E.

SCARLET RUNNER BEANS.

HAVING had a capital supply of these this season, I have been led to make a few remarks about them, in the hope that they may prove useful to those who have been less fortunate during such a scorching summer. Being of an accommodating nature, I am inclined to think sufficient attention is not always given to render them so productive as they otherwise would be were a little more attention bestowed upon them.

My main crop I always grow in a quarter of the garden which is partly shaded by trees, which, no doubt, has had a little influence for good on the crop this year. But I attribute more to the preparation of the ground for the rows, which is done by making trenches 5 feet apart, about the same as for *Celery*, the manure employed to be thoroughly decayed.

I sow a double row of Beans in these trenches, placing the Beans 9 inches apart, which are then covered with 3 or 4 inches of soil from the sides of the trench. When of sufficient height they are earthed as high as the seed leaves and then staked. This earthing fills the trench to within 4 inches of the top, thus leaving ample space for water to be poured in when needed, and which must soak straight down to the roots. In hot dry weather I give them a thorough watering once a week, first using clear water, and then liquid manure. Nothing exhausts this crop so much as to allow the pods to remain on the plants to become old. They are better picked, even if thrown to the rubbish heap, than to remain on the plants. That I hope, however, would be a last resource,

when they are so inexpensive to preserve, and make such an agreeable change for the winter. For the past four years I have grown selected seed of Carter's Champion, and have found it to be a variety to be depended on for quality and productiveness when treated well.—J. COPSON, *Down Ampney.*

WREATH MAKING.

THE hints thrown out by your correspondent "J. H. E." regarding the making of wreaths, will, I am sure, be highly appreciated by many of the readers of the Journal. Numbers of young gardeners who have been reared in private gardens have had very few opportunities of seeing wreaths made, and feel at a loss when at some unexpected time they are requested to make one. I can well remember my first start at wreath-making, and the difficulty I had in keeping the flowers in their proper position on the wire skeleton, which had not the improvement mentioned by your correspondent—viz., the hazel or willow secured inside. Since then I have used cardboard as a skeleton, and find it much better in every respect. It is quite a simple matter to cut out a circle about 1 inch wide in the cardboard, round this tie some green moss, and you have at once a capital skeleton for making crosses. I generally use thin laths nailed together and covered with moss in the same way as the wreath skeletons.

When *Adiantums* are scarce I find *Asparagus plumosus* a very good substitute. It lasts a long time fresh, and is quite as light and graceful as Maidenhair Fern.—WILLIAM LITTLE.

AT a general meeting of the ROYAL HORTICULTURAL SOCIETY held last Tuesday at South Kensington, E. G. Loder, Esq., in the chair, the following candidates were duly elected Fellows, viz.:—T. B. Crundall, George Flemwell, T. W. Girdlestone, Surgeon-General Graham, J. J. Hillier, Major Holland, Walter Kruse, Hugh Low, Miss Ruth Paget, Alfred H. Pearson, Henry J. Pearson, Miss A. A. Rothschild, W. Threlfall.

— THE Royal Horticultural Society's Gardens at Chiswick appear to be taking a large share in preparing for the Colonial Exhibition to be held at South Kensington next year. Very LARGE CONSIGNMENTS OF TREE FERNS, CYCADS, &c., have arrived from New Zealand, Australia, Ceylon, and Antigua, and are now being potted and started into growth. There are hundreds of splendid trunks, most of which have arrived in fairly good condition, but there appears scarcely time for them to form proportionately large heads. A number of fine plants of Filmy Ferns are remarkably fresh, and some trunks of *Todea africana* weigh upwards of 6 cwt. each. Great labour must necessarily be incurred in the management of such a large importation. The large stove is being filled with them, and the Rose house, formerly the orchard house, is being treated so as to provide additional accommodation.

— THE annual meeting of the NATIONAL AURICULA AND NATIONAL CARNATION AND PICOTEE SOCIETIES was held at South Kensington on Tuesday last, Shirley Hibberd, Esq., in the chair. There were present: Dr. Masters, Dr. Hogg, Messrs. G. F. Wilson, G. Paul, H. Turner, H. Cannell, J. James, E. Hill, H. J. Pearson, and Mr. Douglas, Secretary. The report was read and approved. According to the financial statement, the income of the Auricula Society amounted to £87 5s. 6d., leaving a balance in hand of £9 2s. 1d., and that of the Carnation and Picotee Society to £78 2s. 3d., leaving a deficit of £4 2s. 9d. The date of the Primula Conference was fixed for Tuesday and Wednesday, April 20th and 21st.

— THE next Exhibition of the HULL CHRYSANTHEMUM SOCIETY is fixed for Thursday and Friday, the 18th and 19th of November, 1886.

— WE recently observed in the Chelsea nurseries of Messrs. James Veitch & S. TWO NEW CHRYSANTHEMUMS that promise to be of considerable value because of their lateness and purity. They are Japanese varieties, named Domination and Pelican. The former has full flowers with very long drooping florets, pure white, flat, yet rather twisted, and notched at the ends. The latter is equally pure and has broader florets. The character of the flower is of the Dragon type, and is popularly called the White Dragon, Domination having more the character of Meg Merri-les, yet both are perfectly distinct and decidedly attractive.

— IN one of the stoves in the same nursery a batch of small flower-

ing plants of *TOXICOPHLEA SPECTABILIS* suggest how valuable such plants are at this season of the year. They were raised from cuttings in the spring, and range from 9 inches to nearly twice that height. They are in 5-inch pots, and are clustered with small white flowers that diffuse a delicate *Ligustrum*-like perfume that is very enjoyable. Such plants grown by the dozen would be very acceptable in many gardening establishments. They continue attractive for several weeks.

— THE eleventh annual dinner of the LAMBETH AMATEUR CHRYSANTHEMUM SOCIETY was held at the Bridge House Hotel, London Bridge, on Friday evening last. The chair was occupied by Mr. Alfred Pocock, the Vice-Chairmen being Mr. Edgar Ivison and Mr. C. Harman Payne. The company, which numbered between seventy and eighty, consisted of many local residents and honorary members. Among the visitors were Mr. Seymour Keay, the late candidate for West Newington, Mr. William Earley, Mr. William Holmes, Secretary of the National Chrysanthemum Society, Mr. R. Ballantine, the Vice-President of the same Society, and other gentlemen interested in floriculture.

— MR. JOHN CARTER, Keighley, sends a COLLECTION OF PRIMULA BLOOMS, representing some exceedingly fine varieties, and admirably grown. The varieties are as follow:—Princess Louise, very large, (2 inches in diameter), massive blooms, white or blush-tinted; The Queen of similar size and substance, pure white; Emperor, a remarkable variety with large flowers and of a peculiar bright rosy scarlet colour, very effective and distinct; Marquis of Lorne, another of the large-flowered forms of a soft purple colour; Al Crimson and Magenta Queen are both richly coloured varieties, bearing large trusses of flowers; but the most beautiful of all is a double variety named Mrs. Langtry, soft pink in colour, the petals slightly fringed, the bloom of moderate size but very freely produced. For cutting or general decorative purposes this variety is charming, and we commend it to all interested in these useful plants.

— THE annual dinner of members and friends of THE NATIONAL CHRYSANTHEMUM SOCIETY will be held at the "Old Four Swans," 84, Bishopsgate Street Within, on Monday evening, December 14th. Chair will be taken by the President, E. Sanderson, Esq., at six o'clock precisely. The prizes awarded at the recent Exhibition at the Royal Aquarium, Westminster, will be distributed on the occasion. The Exhibition of this Society for 1886 is fixed for November 10th and 11th at the Royal Aquarium, Westminster.

— WE are informed that a CHRYSANTHEMUM SHOW IN THE ISLE OF MAN was recently held in the Town Hall, Castleton, under the management of an energetic local committee. The flowers were a great improvement on those of last year, some of them being very fine. The number of exhibits also showed an advance. In addition to the Chrysanthemums there was also a large and creditable show of cut flowers and fruit. The hall was well filled, the exhibits being ranged in tiers, which allowed the several specimens to be fairly seen. Mr. Nicholson of Roby, near Liverpool acted as judge, and exhibited, not for competition, a collection of handsome Chrysanthemum blooms. The principal prizes were secured by Mr. W. Ambery, Douglas; Mr. J. Looney, gardener to Mrs. Gawne, Ken-traugh; and Mr. J. Murphy, gardener to W. F. Moore, Esq., Crankbourne.

— MESSRS. CASSELL & Co., Ludgate Hill, announce that they intend commencing the issue of a NATIONAL LIBRARY on December 21st, in a series of 3d. volumes, to "represent all periods and forms of thought." The books will be of the records of History, Biography, Religion and Philosophy, Discovery and Enterprise, Plays, Poems and Tales, Natural Science and Natural History, Art, Political Economy, and other subjects." These volumes will be of small 8vo. size, of about 192 pages, in paper covers, or in cloth at 6d. each, and they will be issued weekly. Messrs. Cassell & Co. have enlisted the services of Mr. Henry Morley, and they merit success in their enterprise.

— AT the ordinary meeting of the ROYAL METEOROLOGICAL SOCIETY, to be held at the Institution of Civil Engineers, at 25, Great George Street, Westminster, on Wednesday, the 16th inst., at 7 P.M., the following papers will be read:—"The Influence of Forests upon Climate," by Dr. A. Woeikof, Hon. Mem. R. Met. Soc.; "Report on the Phenological Observations for 1885," by the Rev. T. A. Preston, M.A., F.R. Met. Soc.; "Etudes sur les Crépuscules Rosées," by Prof. A. Ricco; "The Storm of October 15th, 1885, at Partenkirchen, Bavaria," by Col. M. F. F.R. Met. Soc., F.R.A.S.

— THE Select Committee of the House of Commons, appointed on the motion of Sir John Lubbock to inquire into the desirability of establishing a FOREST SCHOOL IN ENGLAND, recently took the evidence of Mr. W. G. Pedder, Revenue Secretary of the India Office, who stated that a Forestal Department was authorised in Bombay in 1846. About that time the revenue of the Indian forests was £40,080. Since then it had risen to a gross revenue of nearly £1,000,000, and a nett revenue of over £400,000, and that, he considered, was undoubtedly due to the increased education of forest officials. Instructors were obtained from France and Germany, but latterly chiefly from France, because it was found that the woodlands of England and Scotland were not so well managed as to enable the managers to give instruction.

— THE CULTIVATION OF THE COCOA-NUT PALM, says "Forestry," is the most remunerative branch of American farming. The trees do not produce much fruit until they are ten years old; but afterwards they continue prolific for nearly a century, and the yearly yield of each is worth, on the average, 15s. in New York. In the extreme south of Florida an enterprising native of New Jersey has planted 200,000 Palms. Land, labour, and trees have cost him only £20,000; and he expects, in two or three years' time, to be earning a clear £120,000 annually, or 650 per cent. interest on his invested capital. The prospect is a seductive one; but lest British fathers with younger sons should dream of sending their hopefuls to grow Cocoa Palms in Florida, we may as well add that in the northern hemisphere the valuable nut can only be cultivated near the sea, and south of lat. 27°, and that the New Jersey speculator, with commendable prudence, has bought up the only tract of land in the United States that is exactly suitable for the purpose.

— IT appears that THE NEW YORK CHRYSANTHEMUM SHOW recently held was an important exhibition, about 8000 cut blooms and 400 plants being shown. Messrs. Hallock and Thorpe secured a large proportion of the prizes, and the plants sold by auction after the Show realised 3000 dollars.

— MR. JOSEPH MALLENDER sends the following summary of METEOROLOGICAL OBSERVATIONS at Hodsock Priory, Worksop, Notts:— Mean temperature of the month, 41·7°; maximum on the 28th, 57·4°; minimum on the 17th, 19·9°. Maximum in the sun on the 28th, 90·9°; minimum on the grass on the 17th, 15·5°. Mean temperature of air at 9 A.M., 40·4°; mean temperature of the soil 1 foot deep, 43·3°. Nights below 32° in shade, six; on grass, thirteen. Total duration of sunshine in the month, thirty-six hours, or 14 per cent. of the possible duration; we had seventeen sunless days. Total rainfall, 1·96 inch; maximum fall in twenty-four hours on the 24th, 0·24 inch. Rain fell on fourteen days. Average velocity of wind, 8·3 miles per hour; velocity exceeded 400 miles on three days, fell short of 100 on nine days. Sunshine was very deficient, and was only two-thirds of the average for the last five years. We stored a lot of good ice on the 20th, I have never taken ice so early before.

— THE December number of the *Botanical Magazine* gives plates of the following plants:—ALOE BAINESI, which Mr. J. G. Baker characterises as "distinctly and decidedly the finest of all the 150 different kinds of Aloe." A plant has been grown at Kew for twenty years, but has not yet flowered, the plate having been prepared from materials supplied by Professor MacOwan. It is a Cape species, reaching a height of 40 or 60 feet and bearing a large head of rosy flowers.

— IN plate 6849 is given a representation of a Chilian tree, RHAPHITHAMNUS CYANOCARPUS, a member of the Verbenaceæ family, and has already passed under three other generic names—Cetharexylon, Duranta, and Poeppigia. It forms a tree 15 to 20 feet high, densely branched, slightly spiny, with small ovate bright green leaves, and bears numerous small tubular white and blue flowers, which are followed by bright blue fruits. It is rather pretty and is hardy in Cornwall, but requires to be grown in a cool house in more northern districts. Rhododendron javanicum var. tubiflora, from Sumatra, has larger paler flowers than the type, but is not equal in beauty to many of the hybrids raised in England.

— A PRETTY but not imposing Orchid is POGONIA PULCHELLA from Hong Kong. It is one of the most recent discoveries of Mr. Charles Ford, the Superintendent of the Botanical Gardens in that island, another Orchid also having been added to the list under the elegant name of Vrydagzynthia nuda. Sir. Joseph Hooker states that the Pogonia "was

first brought to Mr. Ford in 1878 by an officer's servant, who found it on the coast of the south side of the island of Hong Kong. It was planted in the gardens, and flowered in 1879; tubers sent by Mr. Ford to Kew in 1883, and which he procured on the Lofan mountains on the coast opposite to Hong Kong. It flowered at Kew in April, 1885." The plant is dwarf with small round whitish tubers, from which arise the slender scapes of drooping flowers, the lip crimson and white, and the sepals and petals narrow, greenish brown. The leaves are pretty, veined with white on the upper surface, shaded with dark green, and reddish beneath. Two Asiatic Crocuses, Korolkowi and Aerijs, are also figured, the former yellow, and the latter purplish.

CANKER IN FRUIT TREES.

I AM well acquainted with the fact that almost every writer is against me in my conviction that insects are the cause of canker. Only one that I remember has favoured the same line as myself, and that was Mr. Harrison Weir, who had not actually seen the insects, but had cured his specimens of canker on the supposition that insects were the cause of it. I beg very respectfully to say that it does not matter who is against me, because what I write I have proved by observation and practical experiments. If I disagree from others it is with the best motive—viz., to determine the real cause of canker and its cure for the benefit of all. It is laid down for us that it is a disease. I contend that it is no more a disease than is the bite of a dog, causing injury. Insects eating the bark may always be found by careful examination on or near the spot where canker commences.

I am much obliged to "Entomologist" for his note. I ask him, if he still remembers it, whether the piece of wood sent had the appearance of having passed into a "sickly condition" except at the identical spot attacked? I have examined the tree for another specimen, but I cannot find one. It was a piece from a Cobham tree, where it is rare to find canker. And here allow me to recommend any reader who is not acquainted with this Apple to make acquaintance by procuring it. With me it is far before Blenheim Pippin for cropping, early bearing, appearance, and flavour, and as it is of the Blenheim type it readily sells for Blenheims, and commands a good price consequently.

In my opinion trees are brought into a sickly condition by having to support—unknown to an ordinary observer—thousands of minute insects in large trees, and canker follows. I could give details of interesting specimens of cankered wood placed under the microscope for the benefit of fruit-growers, who were astonished by the revelations. I enclose another small specimen of Pear tree wood showing the commencement of the so-called disease, where the insects may be seen. This is from a vigorous healthy tree, a standard in my orchard, where no one would think of canker without close examination. The small tree referred to page 376 was, I admit, a bad specimen to send, but being useless I thought it would answer my purpose. The other piece of wood before referred to was a crown-grafted tree where no ligature was used, so that that was not the cause of canker, and I have other specimens to bear me out.

In reply to "Lathyrus," page 426, I have referred to "Entomologist's" note, but fail to find that he has "contradicted" me. I have never said a word against the "necessary preparation for the roots." I can keep Lord Suffield as free from canker as Keswick Codlin so far, and from late experience I do not think it more prone to canker than others, apart from the transference of insect life. I could give many instances bearing me out, but it would take too much space. I am a great believer and user of liquid manure for fruit trees, and I do not say a word against root-pruning where necessary. I shall be pleased to see what "Thinker" has to say, quite independent of anything I have written.—J. HIAM.

[A correspondent reminds us that Mr. Hiam has not stated his method of preventing canker in fruit trees, or, in other words, of destroying the insects that he believes are the origin of the evil.]

PRUNING DENDROBIUM NOBILE.

MR. PRINSEP, at page 495, draws attention to the above subject, which is a most interesting one; and though it has been a debated question for some time, it remains debatable, the specimens exhibited by Mr. Prinsep at Kensington last May notwithstanding. I had the pleasure of seeing the excellent wood engraving in the Journal of one of the specimens, and was greatly pleased with it; but it also reminded me that I had seen other illustrations of the same kind of plants, and the thought occurred to me that however good an example of cultural skill, under the special and unusual conditions mentioned, the plant was as exhibited by Mr. Prinsep, yet the others appear to be finer and more floriferous specimens, and those, I suppose, were grown in the old-fashioned way. To prevent any misapprehension, I will say at once that I am in favour of old and ugly pseudo-bulbs being cut away, provided they are also useless, under any ordinary cultural conditions; but up to the present time I submit that the evidence adduced has only shown that under very favourable conditions these old pseudo-bulbs may be dispensed with. There are hundreds of cases throughout the country where the satisfactory conditions of growth under the control of Mr. Prinsep and of Mr. Simpson of Wortley are absent, and it is highly important to know whether the pruning system could be advantageously followed in such cases. It would also be interesting to know whether the plants grown and treated as Mr.

Prinsep recommends would be likely to attain a "good old age," say from twenty-five to fifty years.

There is a sentence in Mr. Prinsep's note which rather puzzles me.

pleted its growth, and without having undergone any rest whatsoever, then I will confess myself a "slow believer;" but if he says distinctly that he can and does grow and flower it on its current season's growth

FIG. 77.—ROOD ASHTON HOUSE AND GROUNDS.

He says, "Some Orchid growers are slow to believe that it is possible to make growths and flower them in one season." If Mr. Prinsep means to say that *Dendrobium nobile* will flower freely immediately it has com-

pleted its growth, and without having undergone any rest whatsoever, then I will grant that Mr. Prinsep achieves that which few people achieved before. On the other hand, if he only means that he succeeds in flowering early next year the growths

made this year, then he only achieves that which scores have done before him, but do not make a regular practice of doing for satisfactory reasons to themselves.—READER.

ROOD ASHTON HOUSE AND GROUNDS.

ROOD ASHTON HOUSE is a beautiful Gothic mansion situated about three miles from Trowbridge and about one mile from the village of Steeple Ashton. Its present popular proprietor is Walter H. Long Esq., M.P. for the Northern Division of the County of Wilts, D.L. for Wilts, and J.P. for Wilts and Somerset. Mr. Long is descended from a family of the same name which has for centuries been honourably connected with the county, and various members of the family have been known to serve it in Parliament since the year 1433, certainly a good reason why Mr. Long should still represent us. The family originally lived at South Wrexhall, and according to Leland, the first known ancestor was "One Long Thomas, a stout felawe." As surnames were then becoming general this name appears to have been reversed, and the "stout felawe" became Thomas Long. We could go much further into this highly interesting subject, but except saying that Wrekeshalle (Wrexhall) is first mentioned in the Harl MSS. when "Agnes de la Ferei" was abbess in 1252, turn we to the grounds.

Alighting at the railway station and passing through Trowbridge we very soon pass through the first lodge. At this lodge lives a very old man, who, I suppose, would rather serve Mr. Long than be Emperor of all the Russias. From this lodge to the next—about a mile and a half—is a very pleasant drive. There is a row of Fir trees nearly the whole distance each side, and all the trees are about the same height. The park is truly English, which is saying a great deal; undulating scenery, fine trees, and a lake, the latter containing tench, carp, and perch.

We at last reach the house of the head gardener, Mr. Alexander Miller, who kindly shows us everything worth seeing. First a Pine house, 44 feet in length, with some splendid specimens, and then a plant house of the same size. These houses, as well as several others, are glazed on the modern system—i.e., large pieces of glass embedded in putty, but no putty on the outside, and rivetted down firmly. This gives great strength as well as the maximum of light and heat. Now we come to ainery 100 feet in length, but in four divisions. Theinery contains Foster's Seedling, Black Hamburg, Muscat of Alexandria, and Gros Guillaume. Mr. Miller manages to have a good succession. The Grapes in the first division are eaten, in the second ready to be eaten, third not quite ready, and so on. Mr. Miller has Grapes from April to Christmas, but by different arrangements of heating, &c., he intends having them all the year round. We now pass into another house, 100 feet long, intended eventually for Pines, &c., but at present used for a fine lot of Tomatoes.

Next is the kitchen garden, and I never saw a better. A wall all round it, not a weed inside, and completely filled with everything the palate could desire. This garden is a proof of the value of a good garden education. In the north a gardener is apprenticed, and is turned into the kitchen garden first and made to master that. He has, I believe, at least a year of that before he attempts anything with the flowers. One noticeable feature of this garden was a splendid bed of spring-sown Onions, which had attained a very large size, notwithstanding the dry season. There are several other houses for Grapes, Peaches, Figs, &c., and one long Peach house (.75 feet) full of splendid trees, both of Peaches and Nectarines. We saw some fine specimens of the Peach called "Exquisite." The wasps had found some of these Peaches exquisite, but Mr. Miller intends next year to try whether a good pail of tar will keep them out. Going out of the kitchen garden we get near to the mansion, which, loyal as we are, we could not help thinking something like Windsor Castle. The flag was flying, showing that Mr. Long was in residence. There are some fine specimens of trees here, amongst which we might mention a Wellingtonia 45 feet high, a splendid Weeping Birch, Evergreen Oak, &c. A fine specimen of *Thuopsis dolabrata* planted, we believe, on the day Walter Long, jun., was baptised, September 11th, 1879. Many other fine trees, but we must not forget an old Oak which must have stood there centuries. It is 25 feet round at the height of 4 feet from the ground, and more a little higher up. It is quite hollow, and large enough to hold several men. It forms a happy home for owls. The bark has been nailed on from time to time as it came off. We cannot refrain from mentioning one more tree, a Lime tree, which contains immense bunches of Mistletoe. We have never seen such bunches, even in Covent Garden.

The bedding out is done after the good old fashion. Plenty of Scarlet Pelargoniums and the blue Lobelia, as well as other sorts of Pelargoniums, but no carpet bedding, and here we admire Mr. Miller's taste. The borders are in the shape of various kinds of scrolls, and were designed by him. The view obtained of the flower garden from the mansion is very good indeed.

Altogether the place is well worth a visit, and through the kindness of Mr. Long the beautiful park is open to the public the whole of the year, with the exception of three days.—WALTER CHITTY.

EARLY PRUNING VINES.

THE suggestion of your correspondent, Mr. Iggulden, regarding the "effects of early pruning on Vines" was well timed from the facts he has laid before us; and there is little doubt but many will direct their attention during the next spring and summer to the spurs from which show bunches have been cut, especially those who have not been in the habit of making an "all round" shortening back.

I trust my opinion on this subject at the present time may assist in stimulating others to careful observation on all matters connected with this untimely operation, and let it be proved whether or not this denuding the Vines of a large part of wood and leaves is hurtful.

My interest in early pruning was aroused about three years ago on receiving a letter from a brother gardener and one of the most successful Grape-growers in the middle counties of Scotland, now on his way to a far-off land, where his skill and energy are to be applied to the growing of fruit on a large scale.

He said in that note he thought we are in our infancy in the management of Vines, and one of the points we are far wrong in is the pruning. After some thought he came to the conclusion we are in error in applying our labour and care to the perfect ripening of wood to be cut away in winter and burned; and in order to economise resolved to prune early, expecting what nourishment would have been laid up in the part removed would be appropriated by the parts left.

Happily the experiment was conducted on a small scale, or the quantity and quality of his crop would have been very much impaired, and I may as well give the details of procedure. My friend had the faculty of seeing a long way before him, and tried to the best of his ability to meet all demands made upon him. Not being a close pruner he found it necessary to lead up a young cane to take the place of the old one, and from this he expected to get his best show bunches. On this occasion he had an extra fine rod of Hamburg he had specially prepared in view of a forthcoming international, which he determined to try his new idea upon. This rod was cut about the beginning of October, while the leaves were still green, to about a foot above the place where a second pruning was to be done later on. The following spring it broke moderately strong, but showed poor bunches and never attained to anything like others of the same variety growing side by side. The result from the operation on this Vine was not considered a sufficient test, as the energy of the Vine might have been crippled by the removal of the old rod at the same time with the pruning of the young one; but the same plan was carried out on the laterals of another Vine of the same sort at the same time with a like result, and proved to our minds the evil effects of premature pruning or shortening of laterals.

We often see it affirmed that root-action is late in commencing in spring; would there not be a corresponding period of activity in autumn and early winter in storing food for the spring supply? I think it has been clearly proved that the roots are active long after the leaves have fallen, and everything apparently at rest. But then, is the quality stored during this time of the same value with that previously laid up, which had gone through the regular process of digestion, while the leaves were there and at work? I think not. The future crop depends more on the quality than the quantity of stored sap, and if the source for the production of this supply be removed, to a greater or less degree will the provision for next crop be reduced.

Pruning, in my opinion, is an unnatural process, and has to be resorted to as a matter of expediency from the cramped circumstances and conditions under which growth is sought to be carried on. If this is so, the less pruning the better, and then only when everything is ripe, "Thinker" has touched very lightly on the subject. He thinks there can be no harm done in shortening early provided four leaves are left. I presume he considers these necessary to provide elaborated sap for the buds and wood in their immediate vicinity; but what of the other parts of the plant, not to mention the roots at this, of all, the most important period of preparation for future wants?

It is said that after assimilation takes place the sap has a downward tendency, and possibly the supply from the four leaves might be wanted farther down; in consequence of the supply from above being cut away, this part from where the fruit is expected next would be starved. It may be argued that this sap takes its start downwards, first at the extremity, gathering in and laying up as it proceeds, or it may be said if any part of the plant is deprived of its supply in autumn, the flow in spring will immediately rush to make it up. But these are matters beyond our "ken." Our duty is to work upon the knowledge we have, and strive energetically to obtain what we have not.

Mr. Iggulden remarks that the fine buds in some cases we see, are not what they appear to be. I think one of the causes is this system of early pruning, or before the roots are at rest, while yet the supply of watery matter suited to swell the buds for the production of gross spongy shoots is still going on, but possessing none of the qualities required for the production of good bunches. These opinions will lead to the conclusion that early pruning should be dispensed with, and as many leaves as can be exposed to light be preserved in health as long as they will remain on the Vine.—W. WILLIAMSON.

ONIONS.

I DO not think there is a more important crop grown than these. If we lose our Cabbage we can use Savoys or Brussels Sprouts. Peas may take the place of Kidney Beans, and Spinach of Cauliflower, but Onions stand by themselves, and when they are lost nothing can replace them. They are in daily demand in all kitchens of any importance, and their total absence makes it very inconvenient for the cooks and unpleasant for the gardeners. True, Onions may be bought very cheaply, but buying is not satisfactory where there is a garden. For the last twelve years at least we have never had a failure of our Onion crop. We grow upwards of a quarter of an acre annually, and we rarely lose a score of plants from any cause. The young plants grow rather better in a light soil at first, but for a really fine crop we prefer growing them on heavy land.

Here at first they may be backward, but in the end, and especially during hot weather, they swell up splendidly. When once the grubs have found their way into a few rows it is very little use in trying to get them exterminated. They bore up through the plants from the bottom, and anything which would kill them there would also kill the plants. Prevention in this case is better than cure, and now is the time to deal with preventive measures.

The Onion ground for next year should be cleared at once, dressed, and dug over. The best of all dressings we can use is gas lime. We spread about an ordinary wheelbarrow load to every 20 square yards, and then dig it in, and after this the soil will remain quite free from all insects for the next twelve months. When gas lime cannot be procured soot should be substituted at the same rate, and, failing this, a sprinkling of salt will answer the purpose very well. The manure which is used before sowing time is also freely mixed with soot or salt, and when these inexpensive precautions are taken before sowing there need be no anxiety about the crop. If all the Onions in cultivation were grown together and classified by some impartial hand I do not think the numbers of distinct sorts would exceed half a dozen. The old forms, such as James's Keeping and Bedford Champion are quite distinct.—A KITCHEN GARDENER.

SNOWDROPS (*GALANTHUS*).

HAVING had occasion recently to put my hardy bulbs in order, these charming harbingers of spring came in for the attention they richly merit. I am particularly fond of Snowdrops, and thought a few notes upon them as a family would be welcome. The majority of amateurs are not aware of the number of different varieties there are in cultivation; albeit, some of them are very scarce. I suppose there are only three species, but the common one, *Galanthus nivalis*, varies considerably. There are several well-marked forms. I well remember what a rich collection of these varieties the late Rev. Harper Crewe got together and cherished, some of which, I fear, are lost, but the majority passed into the hands of E. G. Loder, Esq. of Weedon, where they will be well cared for. In that excellent work, Gill's "Dictionary of Gardening," there are four figured, but there is a slight confusion in the nomenclature; the one named *G. Elwesii* is *G. nivalis virescens*, and *vice versa*, which form is extremely scarce and pretty, and I am glad to see it figured in that work. There is another named *reflexus*, which I have never seen in a living state, although I possess a reflexed form of *G. Elwesii*, but do not consider it desirable on account of the narrowness of the segments. Mr. Baker arranges *G. Imperati* and *Redoutei* under *G. nivalis*, but I am inclined to think that it is sufficiently distinct for separation. The foliage is very broad, and it is very strong-growing and much later in bloom, but this latter character may not stand for much when the variability of *nivalis* in respect to flowering is considered; for there is one variety, which is very early in the year, and Mr. Harper Crewe used to have one named *octobrensis*, which bloomed in October and November, thus vying with the winter Croci.

Happily all the best of the Snowdrops are now reasonable in price. I have seen them offered at a low figure in most lists this season, so that all lovers of them should become acquainted with at least five distinct kinds—viz., *nivalis*, *Imperati*, *Elwesii*, *plicatus*, and *Redoutei*. As they are all equally easy of cultivation, fine clumps may be made in the garden or on the rockery, or even accommodated in 6 inch or 7 inch pots, and used for the embellishment of a cool house, for which purpose they are charmingly suited. One item it is desirable to bear in mind when planting or potting, is their fondness for a little well-decayed manure; this improves them very much. *G. Elwesii* in particular develops much larger blossoms when treated to manure, and the size of this species improves greatly as it gets established, and it well deserves the title of "Giant Snowdrop" when in its best state. For floral decoration it should quite eclipse the common kind, as the flowers are much larger, of such a charming form, and with more substance in the segments, and I would strongly advise private growers who esteem a buttonhole of Snowdrops to plant it freely at once, as it is quite time it, and, indeed, all the kinds, were planted.

The common form being offered so cheaply is largely used for massing and naturalising, as the price of all the others, except *Elwesii*, prevents their being used so lavishly. I notice that imported bulbs of the latter are now offered by good houses at a low price by the thousand; and here let me caution purchasers against expecting too much from these bulbs the first season, for the flowers will certainly be small, and by the second or third season they will improve much, especially if some manure is given when planting. The following notes upon the different kinds will show their distinctive characteristics.

G. ELWESI (*Elwes's Giant Snowdrop*).—Truly the finest of

all the Snowdrops; the outer divisions are large, more rounded than in any of the others, the outline of the flower being more globular; inner divisions marked deep green at the base. This is always a distinguishing feature, whatever are the other varying characters of the flower. The flower stems grow 9 inches high when strong; leaves broader than those of the common variety, very glaucous. It is equally as early in bloom, sometimes appearing before it. Native of Asia Minor ("Botanical Magazine," t. 6166).

C. IMPERATI (the Italian Snowdrop).—This is undoubtedly a very large form of *nivalis*, but it is later in flowering. The buds are large and fusiform, quite distinct from any other; the outer divisions are long, much narrowed at the base, clear white; the inner divisions are rather deeply notched at the top, with the characteristic green blotches beneath. It is a native of Italy, and can be obtained at a very reasonable rate.

G. NIVALIS (the common Snowdrop).—This and its double form are too well known to need any further mention, but the following kinds are scarce, and some very rare indeed—*Virescens* has the inner divisions almost entirely covered with green, and a few stripes of the same colour on the outer divisions; *Shaylockii* is very similar, but the flowers are longer; *lutescens* has a decided yellowish tinge upon the inner segments and at the base of the outer ones, and is very pretty; *Melvillei* is a large form sent out some years since by Messrs. Veitch & Sons of Chelsea, somewhat resembling *Imperati*, but distinct from it; *cocyrensis* has a small flower appearing very early in January, sometimes at Christmas; it is, however, very scarce, I have only met with it once. Several others might be enumerated, but they are not to be had for love nor money.

G. Plicatus (the Crimean Snowdrop).—The flowers of this species resemble those of *G. nivalis*, except that they are rather larger and borne on much taller stalks, but the leaves are quite distinct, having a distinct fold on each side, hence the specific name *plicatus* (folded); it is rather uncommon, and never appears to be imported in very large quantities, but it is most desirable ("Botanical Magazine," t. 2162).

G. REDOUTEI (*Redoute's Snowdrop*).—Syn. *G. nivalis latifolius*. The foliage of this is bright green and very broad, much longer than any, and it is the tallest grower. It much resembles some of the Snowflakes, and is quite a departure from all the others; the flowers are rather thin in substance, but extremely pretty, well meriting a place in all collections.—R.

JUDGING PEARS AND GRAPES AT THE BATH SHOW.

I BELIEVE I am justified in stating—indeed, I claim the right to do so—that your reporter was an exhibitor, but whether a disappointed one or not I cannot say—in the fruit classes, in which, as already stated, I assisted in making the awards. I mention this fact so that your readers may the better understand our relative positions at the Show in question, and therefore be the better able to arrive at a correct estimate of what has been said by both parties on the subject. And had your reporter given his name your readers would see that I was as competent to give an opinion on fruit or any other garden produce as he is, notwithstanding his assertions (by implication, p. 490) to the contrary. Your reporter says, "Not only did I express an honest opinion (which I may remind him does not necessarily mean a correct one), but it was also the opinion of many practical gardeners, all known to both Mr. Ward and myself, and whose names I could give, that errors of judgment occurred, more especially in the Pear classes." Your reporter having made this statement for the purpose of supporting his own remarks, I think it is a pity that he should have considered it part of his duty to withhold the names of the "many practical gardeners" who were of the same opinion as himself, because had he furnished your readers with the names of these gentlemen they would then be able to estimate the "value" of their opinion.

Your reporter repeats that, "in his opinion, Mr. Taylor's Grapes ought to have been first;" and I repeat, as one of the Judges who made the awards, that they and all the other exhibits in the fruit and vegetable classes were placed in their proper positions, and that the awards were not made in a haphazard sort of way, but strictly, and with great care, in accordance with the points of merit which guide competent Judges like the gentlemen whose names I mentioned at p. 465 as being two of the most able and successful growers, exhibitors, and judges of fruit in the country, and, I may add, with whose awards I have always been satisfied whenever they have judged my own exhibits. When acting in a similar capacity myself I always endeavour, as I did at Bath conjointly with a brother gardener, to be guided by their standard of excellence and to make the awards to the most meritorious exhibits by judging them according to their individual and collective points of merit. Hence my using the names of Messrs. Coleman and Wildsmith in connection with this subject. But I certainly decline to accept the opinion of your reporter as being correct until he has shown me by practical results and consistent statements a capacity to express a sound, practical, and unbiassed opinion on a matter of such importance to horticultural societies, exhibitors, and judges alike. Your reporter finding no just grounds of defence of his criticism of the awards, misquotes me when he says that "the second-

prize stand of Grapes was not so 'gappy' as Mr. Ward represents, neither were the third-prize bunches so 'dirty,' as he states they were." This statement is wrong, as a reference to my former note will prove, as I did not use an adjective in connection with either "gappy" or "dirty." This being so, your reporter in the few sentences which I have just quoted from his note unintentionally admits that the exhibits in question were what I represented them to be—"gappy" and "dirty." Your correspondent assumes too much when he says that "it would have been better if Mr. Ward had let my criticism pass unnoticed!" Had I done so I have no doubt it would have been more agreeable to his wishes to be allowed to pose as the champion and the mouthpiece of one or two dissatisfied exhibitors. I have nothing to fear from the result of this discussion, and am not disposed to lie silent, even to oblige your correspondent. Your reporter—I wish I were at liberty to refer to him by name—says, "What if Pitmaston Duchess were in one dish, and that very small sort Winter Nelis in another?" Simply what happened at Bath—namely, that the collections consisting of twenty-four even-sized fruit of a size between the two varieties indicated, provided they were of as good quality as the fruits constituting the irregular collections, would be "placed" and the others "passed." The fact (communicated to the Journal, page 470, by Mr. Bannister) of the Committee of the Bath Show having awarded that exhibitor an equal first prize for his collection does not alter the awards of the Judges in the least, nor the merit of the collection which the Judges "passed." The prize referred to was given to soothe the feelings of—as far as I could gather at the Show—the only dissatisfied exhibitor in the fruit classes, and only goes to prove that the Committee, out of motives more charitable than wise, did that which they certainly had no right to do without having first obtained the sanction of the Judges who "passed" the said collection—a sanction which it may be rightly assumed no competent men would give. If the action of the Bath Committee in this case goes for anything it is to establish a precedent for dissatisfied exhibitors to fall back on, and one that other committees should avoid as affecting the interest and reputation of themselves as men of business and the society which they represent as a body.

I must, with the Editor's permission, return to the Grape question by telling your correspondent that it must be sufficient for him to know, as it is for me, that what I stated at page 465 in reference to the Grapes which Messrs. Nash and Taylor staged at Bath being placed in the same position at Bristol the following week is substantially correct; indeed, your correspondent almost admits as much when he says, "even if they were," two bunches only, instead of three as at Bath, were shown, adding, "this might easily have made a material difference." I should like to know in what way this could possibly have made a "material difference" in determining their respective positions. Does he mean to say that Mr. Taylor left his best bunch at home and Mr. Nash his worst? They "might" have done so it is true, but it is highly improbable. Your correspondent says, "It has yet to be proved that consistency and correctness of judgment are necessarily conjunctive." It is quite evident they are not, as is shown by your correspondent's report of the Bath Show (page 425), wherein, as I pointed out at page 466, in speaking of Mr. Taylor's second-prize stand of Alicante he hinted, and now (page 490) he says "ought to have been placed first," and then proceeds to accord the "same position" to the third-prize stand. And, again, in his report of the Bristol Show (page 476) the Grapes (Mr. Nash's) which were referred to in his report of the Bath Show the previous week as "not being well coloured" are here referred to as "being of the highest order." So much for your reporter's consistency of judgment. Your reporter says he has great respect for Mr. Nash, and I may be permitted to say that now, as at the Show, I have nothing but good wishes to offer any of the gardeners whose name your reporter has been instrumental in mixing up in this subject. But I should like to know what the respect or good wishes which judges may bear for exhibitors have to do in determining their respective positions. And these remarks are equally applicable to those who make reports of the shows.

I feel I should be wanting in respect to "A Thinker" if I allowed his remarks at page 485 on judging to pass unnoticed, and which I trust may have a salutary effect on exhibitors, press attendants, judges and committees alike. It is, as he states, an established practice for press attendants to judge the awards of the adjudicators, and for my part I should be sorry if it were otherwise. I know that errors of judgment do occasionally occur, but very rarely indeed when the awards are made by successful growers and exhibitors of plants and fruits in the respective classes. I am aware that it sometimes—though happily very rarely—happens that men who had not previously attended a show in any other capacity than that of a visitor or an unsuccessful exhibitor have been selected by the "committee of management" to determine the relative merits of the exhibits of practical men, and I need not say with what results. Here the practical press attendant points out the inconsistency and unjustness of the awards; and, having made himself acquainted with the unfitness of the men to perform such important duties, he censures pretty strongly—if not, he ought to, not the men who doubtless made the awards to the best of their judgment, but the committee who was responsible for the selection, and who ought to have chosen men of ability and paid them for their work. If the Judges erred in their awards in one of the Grape classes at Bath the Judges at Bristol, both excellent fruit-growers, repeated that error. I also beg to remind "A Thinker" that I did not, and never have done so, "advance the principle of uniformity throughout a collection as being of greater moment than individual merit, either of Pears, Chrysanthemums, or anything else;" but what I said, and say still, that "uniformity throughout a collection in connection with individual

merit should guide the Judges in making their awards." And if any practical man tells me in these columns that this dictum is not sound I will say no more on the subject. The collection of Pears which secured first place consisted of good-sized, even, clean, and ripe fruits of Marie Louise, Louise Bonne of Jersey, Beurré Bosc, Beurré Diel, Beurré d'Arenberg, and medium-sized fruit of Van Mons Leon Leclerc under the name of Beurré de Capiaumont, and which the gardener, who made the report of the Show for this Journal, admitted at the time was wrongly named, although it afterwards crept into his notes somehow under that name. I merely mention this for the information of your able and unbiassed critic, "A Thinker," as he has referred to this somewhat small Pear as being "extraordinarily large or the others correspondingly small" to make the collection uniform in point of size. I may add that the second and third-prize collections were composed of similar varieties of a high order of merit.

Accepting "A Thinker's" improved illustration of stands of six incurved blooms of Chrysanthemums on the score that they are regularly seen and judged at shows. In one stand the blooms decrease gradually in size from the back row to the front (which was not the case with Mr. Bannister's Pears, inasmuch as two varieties were larger than the fruits on the other three plates, while those, Pitmaston Duchess, on the sixth plate were considerably larger than any of them). This stand receives a total of twenty-six points. The stand in competition is so even that the blooms examined individually are worth four points each, or a total of twenty-four points. "A Thinker" then asks if it would be right to give the first prize to the stand that loses in intrinsic merit—be it observed he allows nothing for evenness of collection—by two points, and the second prize to the stand that wins by that number. Now if evenness of collection count for nothing, I ask, How is it that we invariably find in the special reports of the metropolitan and provincial shows the expression that "so-and-so was first with a good 'even' collection of fruit, vegetables, or plants, or, as the case may be, 'even' stand of Roses, Dahlias, or Chrysanthemums?" It is the same with a collection of Grapes. Evenness of bunches throughout should count in connection with individual and collective merit. I join with "A Thinker" in saying that there can be no fairer subject for criticism than this, and in expressing a hope that nothing but good feeling and fellowship may prevail in any discussion that may ensue. In conclusion, I may be permitted to say that in what I have here written there has been no intention, consistent with defending my own case, to wound the feelings of anyone. It is one thing to make a charge, but quite a different thing to adduce facts to prove that charge; neither can the groundlessness of a charge, however slight, be conclusively proved in a short paragraph. Hence my apology for this rather long letter.—H. W. WARD, Longford Castle.

[We have received a letter from Mr. Bannister, in which he states the weights of the Pears (four fruits to a dish) in his Bath collection, except as regards the Pitmaston Duchess, which were given away by the owner of them the day after the Bristol Show, where the collection was awarded the first prize "against fruit much superior to that staged against them at Bath." The Judges of the Pear classes at Bristol were Mr. Thomas Shingles of Tortworth, and Mr. John Austen of Witley Court Gardens, who both in letters before us testify to the excellence of the fruit. The weights of the four fruits in each dish were—Conseiller de la Cour, 32½ ozs.; Doyenné Boussoch, 32 ozs.; Marie Louise, 29 ozs.; Glou Morceau, 27½ ozs.; Easter Beurré, 27½ ozs. Mr. Bannister says the Bath Committee awarded him an equal first prize after both himself and Mr. Ward had left the Exhibition. Whether this is a wise innovation or not is a fair matter for discussion, as also is that of the principle on which products are judged as to whether the general evenness of a number of fruit or flowers in a class shall have greater or equal weight with the merits of the dishes or blooms as determined individually. When general evenness is combined with individual excellence there is obviously no question for discussion. Mr. Ward having defended himself fully as a Judge at the Bath Show the discussion on that particular subject must cease. On this account we do not insert a long letter from "A Bath Amateur," the publication of which could not possibly do any good. It may be condensed into half a dozen words—"The report of the Bath Show was a fair one."]

ROYAL HORTICULTURAL SOCIETY.

DECEMBER 8TH.

THE last meeting of the year was a small one, very few exhibits being contributed, and it formed a most striking contrast to the extensive and beautiful shows that have been held in the conservatory during the year.

FRUIT COMMITTEE.—Present: Harry J. Veitch, Esq., in the chair, and Messrs. John Lee, J. Burnett, J. Willard, J. Woodbridge, G. T. Miles, G. Paul, F. Rutland, R. D. Blackmore, and G. Bunyard. The most interesting exhibit were some bunches of the black Grape Winter King, shown by Mr. B. S. Williams, but although it has been previously exhibited several times the Committee expressed no opinion concerning its merits. It is said to have been raised in this way. Five years ago Gros Colman was grafted on a Vine of Raisin de Calabre and produced a different variety in colour, berry, and flavour. It has now been grown for two years on its own roots, and bunches have been twice shown from Vines so established. The berries are oval, of good size, with a thick skin and a brisk rather pleasant flavour; the bunches are compact without shoulders, and bear an excellent thick bloom. It is a good-looking variety, and is distinct from Gros Colman. Several varieties of Apples were shown for the opinion of the Committee. Mr. A. Miller, Rood Ashton Gardens, sent fruits of a variety called the Rood Ashton Seedling, thought to be something like Greenup's Pippin, but it was passed, one fruit being over-ripe. Mr. J. C. Parker, Boxbournebury, showed a seedling Apple not considered of special merit. Mr. T. Woolford, nursery

man, Atherston, sent samples of an Apple called Packington Free Bearer, a local dessert variety in use November and December, said to be a very free bearer. The Committee thought it "a nice Apple, but not so good as others in cultivation." Mr. Hutchison, Haggerston Castle, Northumberland, also sent an Apple of oblong form, but unnamed.

FLORAL COMMITTEE.—Present: G. F. Wilson, Esq., in the chair, and Messrs. James O'Brien, Henry Williams, H. M. Pollett, J. Dominy, H. Ballantine, John Fraser, T. Baines, J. James, H. Herbst, W. Bealby, H. Bennett, J. Child, Shirley Hibberd, James Douglas, H. Cannell, W. B. Kellock, M. T. Masters, James Hudson, H. Turner, G. Duffield, and F. R. Kinghorn.

Sir Trevor Lawrence, Bart., M.P., showed several interesting and beautiful seedling *Calanthes* from *C. vestita*, *C. Veitchii*, and others, one of the best being *C. porphyrea*, which was certificated. *C. burfordensis* has a large rich crimson flower, similar to a highly coloured *C. Veitchii*; *C. amabilis*, also one of the *Veitchii* group, and has rosy flowers with a white eye; *C. aurantiaca*, one of the *vestita* section, has white flowers and a deep orange centre; *C. casta*, of the same type, being pure white. They are all very beautiful forms, and attracted much attention. Messrs. J. Veitch and Sons, Chelsea, showed a plant of *Chrysanthemum Domination*, a free-flowering variety with white, flat, or slightly quilled, spreading, and drooping florets. *C. Dorman*, Esq., The Firs, Laurie Park, Sydenham (gardener, Mr. White) sent a plant of *Odontoglossum Humeanum*, with white flowers—the lip white, the sepals brown, and the petals barred with yellow at the base. It is like a fine *O. maculatum*. W. Vanner, Esq., Camden Wood, Chislehurst, sent a specimen of *Barkeria Vanneriana*, with lilac purple flowers, narrow sepals and petals, with a white blotch in the lip. Mr. Rallend, Hampstead Heath, showed a distinct variety, said to be a sport from *Chrysanthemum Duchess of Albany*, which in general character much resembles *Belle Paule*, the florets recurved or drooping, slightly fluted, yellow edged with red. Mr. J. James, Woodside, Farnham Royal, exhibited plants of *Primula Purity* and *Argus*, both Fern-leaved, the former with a large, substantial, well-formed, pure white flower; the other of a crimson tint. Messrs. J. Carter & Co., High Holborn, exhibited stems of *Boussingaultia baselloides*, a peculiar trailing plant from South America, with slender stems bearing numerous tubers. A vote of thanks was awarded.

Messrs. H. Cannell & Sons, Swanley, had a beautiful collection of Zonal *Pelargonium* blooms, comprising the following admirable varieties:—*Kate Greenaway*, bright pink; *Norah*, bluish white; *Crocus*, scarlet; *Eurydice*, bright pink; *Jealousy Improved*, orange scarlet; *F. Kaufer*, violet crimson; *Queen of the Belgians*, pure white; and *Swanley Gem*, salmon with a white eye, very large and handsome. A stand of the superb double Ivy-leaf *Pelargonium Madame Thibaut* was also shown, the flowers of good form and very full. A collection of single and *Anemone Chrysanthemums* tastefully arranged also added much interest to this collection. A silver-gilt Banksian medal was awarded to Messrs. H. Page & Son, Teddington, for a group of about 300 *Cyclamens* of varied tints, the pure white *Albion* being exceedingly fine, as also were *Queen of the White* and *October White*.

First-class certificates were awarded for the following plants:—

Calanthe porphyrea (Sir Trevor Lawrence, Bart., M.P.).—A lovely hybrid partaking of the *hematodes* in the form of the flower, the lip cupped and spurred, light in the centre with a few darker spots, the other portion with the small acute sepals and petals being brilliant rosy crimson.

Chrysanthemum Boule de Neige (R. Owen, Maidenhead).—A decorative reflexed variety of great merit. The blooms of moderate size, the florets flat, equally spreading, and pure white. The plant is dwarf in habit, very free, and late.

Chrysanthemum Queen of the Yellows (H. Cannell & Sons).—A single variety with even-spreading bright yellow rosy florets. Very neat and pretty.

SCIENTIFIC COMMITTEE.—The Hon. and Rev. J. T. Boscawen in the chair. *Sclerotia in Stems of Chrysanthemums*.—Examples of these described by Mr. W. G. Smith in *The Gardener's Chronicle* were forwarded by him, as also an abnormal form of *Lentinus lepideus* (Agaricini), closely resembling a branching *Clavaria*, from a coal-pit near Stoke-upon-Trent. It is often phosphorescent when in this state in mines.

Produce of Large Palmate Potato.—A Potato much resembling a hand in form was sent to the Scientific Committee in November, 1884. It weighed 15 ozs. On being planted the produce in 1885 was 8 lbs., or more than 800 per cent. Such a result would seem to corroborate those at Chiswick—namely, that whole sets usually give a much greater produce than those which have been cut, the former presumably supplying more nourishment, and, therefore, greater vigour on commencement of growth.

Results of Experiments on Earthing of Potatoes at Chiswick.—Dr. Masters brought a preliminary report, observing that through the absence of *Peronospora*, as in 1884, the object of the experiment failed; but the general results of produce under the different methods of treatment corroborated those of last year. He summarised them as follows:—1, Earthing up produces a crop of more uniform and of superior quality, even if less in quantity; 2, that bending the haulms occasions a diminished yield; 3, that a larger aggregate produce is derived from planting whole tubers than from the employment of cut sets. It was suggested that the Sub-Committee should continue the experiment next year, but with fewer rows, and confine the observations to testing the Jensenian method of moulding should the disease occur.

Delphinium, fasciated.—Mr. Boulger exhibited specimens, about 5 feet long, which had occurred on the same plant for two or three years. Dr. Masters observed that a *Holly*, var. *Doningtonensis*, is particularly liable to fasciation, as also are the *Hollies* at Bearwood, Bagshot. Mr. Boulger was inclined to attribute it to poverty of soil. Hon. and Rev. Mr. Boscawen remarked that fasciated stems often occurred from the same root of *Asparagus*.

Reserve Materials of Plants in Relation to Disease.—Rev. G. Henslow called attention to a paper by Mr. D. P. Penhallon in the "Canadian Record of Science" (vol. i., No. 4, October, 1855), in which the author fully corroborated a single result of a large series of experiments carried on at Houghton Farm in 1883, to ascertain (amongst other objects) a cure for Peach Yellows. In only one instance was the Early York Peach very decidedly benefited by the special manures applied, and that was with muriate of potash. "Instead of small abnormal and coloured leaves in early

July, the foliage developed into organs of good size and a fine healthy colour, while the growth was also fine (1883)." The cause of the disease he had found to be localisation of starch in the bark, &c., during the summer, instead of its being utilised for growth. In the author's latest communication he calls attention to the fact that in 1871, Wobbe and Schröder demonstrated by their experiments on Buckwheat the influence which may be exerted upon the distribution of reserve material by an abnormal food supply. Chlorine and potash were found to have important bearings upon the products of assimilation; potash being essential to the formation of reserve matters, while chlorine was found to bear a most important relation to their final distribution, and that by withholding chlorine, starch accumulated in the bark and leaves, particularly in young growth. Restoration of chlorine gradually effected the distribution of starch and restored the normal state of health. Acting on these results, and applying them to the case of Peach yellows Mr. Penhallon gives the following analyses to show the beneficial results of a similar application of chlorine.

	FRUIT OF CRAWFORD'S EARLY.		WOOD OF DITTO.	
	Healthy.	Diseased.	Restored.	Diseased.
Ferric acid.....	0.58	0.46	0.52	1.45
Calcium oxide....	2.64	4.63	54.52	64.28
Magnesium oxide..	6.29	5.49	7.58	10.28
Phosphoric acid ..	16.02	18.07	11.37	8.37
Potassium oxide ..	74.46	71.80	26.01	15.67
	100.00	100.00	100.00	100.00

These analyses, before and after the application of the muriate of potash, made it at once clear that in the diseased the ash contains more phosphoric acid and lime and less potash. Consequently a number of diseased trees were treated with muriate of potash. "After the lapse of a few years they lost all appearance of disease, and were restored to such a condition of health that up to the present time they have been most profitable in their production of fruit." . . . Hence, "So far as chemical data could determine, the disease was caused by, or, at least, associated with, imperfect nutrition (1885)."

Crocuses, Dried Specimen of.—Col. Clarke exhibited a series of twenty-five species, illustrating the various characters of the perianth and stigmas, the latter organ being regarded as an important classificatory character.

The Chairman.—As this was the last Meeting a vote of thanks was proposed by Dr. Masters, and seconded by Col. Clarke, to the Chairman, Sir J. D. Hooker, and the hope was expressed that he would continue to hold the office in the ensuing year.

PINE APPLE PLANTS IN WINTER.

THE wintering of Pine Apple plants is a more difficult matter than growing them in summer. Those with perfect houses and a complete system of heating may think little or nothing about getting their plants safely through the winter, as the change from summer, so far as heat is concerned, will be slight; but many others with old houses and pits and deficient heat, will be less sanguine, and may experience much difficulty in keeping the plants healthy. We have only one row of 4-inch piping round our Pine house here. It is rather a large lean-to house, and from October until April the temperature is often so low as 40°. A pit for successional plants is much the same, and gave us a great deal of anxiety; but I do not mind it much now. At first we watered our plants at the roots, in much the same way as I had been in the habit of doing in a temperature of 65°; but this I soon found would never do, as the foliage became quite yellow by the spring and the plants so unhealthy that it took them a long time to recover after the good weather came. This does not happen now, however, as we have got into the habit of dealing very sparingly with the water in the winter. Suckers potted in September have received no water as yet, and probably they will not be given any until after they have been transferred to their fruiting pots in March. They are plunged in leaves with a gentle bottom heat, and the condition of their soil might be termed rather dry, but they root freely in this, and the leaves are as healthy and green as we could desire.

The successional plants were watered about the middle of October, and unless it is those which are started into growth in January, no more water will be given them until March. Those in fruit receive a little more water, but very little, and it is always mixed with a small quantity of guano. Altogether the whole of our Pines are kept decidedly on the side of dryness from October until March, and in my opinion it is simply astonishing how well they succeed in a very low temperature when particular attention is paid to this condition.—J. MUIR, *Margam*.

THE INSECT ENEMIES OF OUR GARDEN CROPS.

THE CABBAGE.

(Continued from page 365.)

BOTH in gardens and in fields the Cabbage suffers from insects which would often be greatly reduced in number, or altogether absent, were more care bestowed upon the soil previous to sowing or planting. Rotation of crops, too, is a capital practice, but sometimes the result is that the enemies of one vegetable, having done execution upon that, are left, almost undisturbed, in the ground ready to begin operations upon another vegetable that next occupies the space. Not unfrequently it happens that Cabbages are grown upon land where there has previously been corn, grass, or Turnips. It does not surprise us, then, to hear a complaint that they have gone wrong through the insidious attacks of wireworm or the crane-fly maggot, involving trouble and loss which might have been avoided had suitable measures been taken. One important point is, with reference to the wireworm especially, that, as far as possible, the soil should be well broken up, no lumps of earth or tangles of roots being left

for this insect to shelter in. Gaslime, well worked in, is a capital application where the presence of these insects is a known fact, although a correspondent has recently stated that he found the wireworm defied this agent; I can hardly believe that would happen, provided the article was good and rightly applied. Any stimulating manure, chemical or other, when freely mixed with the soil before planting Cabbages, will lessen the probabilities of injury from these and most subterranean feeders. Some advise the paring and then burning of the surface of soil that is infested with the crane-fly maggot. This will certainly prevent after mischief by stamping out this insect in that particular spot, but there are some objections to this proceeding unless the case is a serious one.

Passing, however, from the larva of the crane-fly, one chiefly a foe to the cereals, and only now and then damaging to Turnips and Cabbages, we come to the larva or maggots of other flies that do special damage to the latter vegetable. Happily the season of 1885 having been dry has not favoured the increase of several of the Cabbage pests, and the maggot of the Cabbage fly (*Anthomyia Brassicæ*) though it has been noticed in gardens and fields, has not been greatly injurious. Had there fallen heavy rains during the summer the plants might have died off frequently from the combined influences of heat and moisture after they were weakened by the attacks of the insect, which bores into the roots and the base of the stem, feeding concealed till mature. It then quits the plant and shelters under the earth, the fly appearing in two or three weeks. The last brood of the season remains, however, unchanged through the winter, to emerge winged during the spring. The reduction, or killing off, of this brood is therefore an important point, and the best step to take is to clear away the surface soil in October or November about autumn or winter Cabbages, for it may contain pupæ of the insect. It is also very undesirable to grow Cabbages year after year on the same ground, a plan which saves the flies the trouble of a journey. To distinguish this fly from other species, it should be stated that the legless tapering maggot is of a whitish colour, with two brown points at the tail, in length scarcely the third of an inch. The pupa is of a reddish brown, slightly spotted with black. In its perfect state the insect closely resembles the Onion fly, but is less, and has more dark markings upon the slender body than that insect possesses. The Onion is never touched by the larva of the Cabbage fly, but it makes occasional attacks upon the Turnip. There is evidently a rapid succession of broods during the summer, perhaps four or five some years, varying with the weather. Manuring, especially if superphosphate or ammoniacal compounds be used, strengthens Cabbages against this pest.

Of minor importance is the insect popularly called the root-eating fly, and *Anthomyia radicum* by Curtis, distinguishable from the preceding by the fact that the larva or maggot, though similar in size, is of darker hue, being yellowish or brown, but the pupa, on the other hand, is much paler in colour than that of *A. Brassicæ*. There is not much difference in their habits, only the maggot of *A. radicum* devotes itself almost entirely to the roots of the vegetable, seldom advancing upwards into the stem. Some districts of Germany have been greatly troubled with this insect, and on the Continent it has been noticed that the larvæ, in some summers, occur very numerous in dung; hence, where this article is applied as a manure, it is no wonder to find the Cabbages and Turnips (and possibly other vegetables) injured subsequently. It has been stated that where spent Hops can be obtained, if they are distributed round the stems of Cabbages, they check the increase of this species, and also of other insects that are apt to give trouble.

Enemies, which from their minuteness may seem to be despicable, yet by their numbers accomplish mischief in sundry cases, as does the little fly *Aleyrodes proletella*, or the Cabbage powder-wing, one responsible for the browning or withering of many Cabbage leaves, especially during autumn. Looking like a tiny whitish moth, and akin to a well-known pest of the Tomato, it is really a species of bug, and pursues the same plan as the scale insect, clinging to the leaves closely, while it exhausts them of their juices by means of a rostrum or sucker. We may find this insect upon Cabbages in any month of the year, but the autumn shows us most of them, at least in the fly state. As much harm, or more, is done by the larva or grub, which, from its small size and pale hue is usually unnoticed by gardeners. Burning all leaves seen to be infested is an obvious precaution, and plants that are beginning to languish may be syringed with clear lime water, tobacco water, or a solution of softsoap.

Then, although Cabbages may be noticed to have feeding upon them more than one species of aphid or "blight," there is a species that is peculiar to the plant, and so is called *A. Brassicæ*. These occur during the spring and summer, and even late in autumn they will be discovered sheltering in the folds of the leaves. The young Cabbage aphid is yellow, when older it becomes greyish green; the winged form is of a brighter green, the head, legs, and antennæ dark. For killing this pest the usual syringings or drenchings are applicable, or dusting at an early period with lime or soot. The drier the plants, especially if the weather be warm, the greater the increase of the aphides, which then appear winged and distribute themselves in various directions. Keeping the Cabbages well watered is at all times a check upon the progress of this enemy.

Occasionally the roots of Cabbages are covered with galls that usually appear in clusters, but are now and then solitary protuberances also arise from a vegetable disease called "club" resembling these; the galls, however, on opening are discovered to have within them a plump yellowish maggot which the other swellings lack. This maggot in due time develops into a small beetle or weevil named *Centorhynchus sulcicollis*, quitting the root-gall ere pupation to enter the soil, where it makes a cell, mixing particles of earth with a gummy secretion. It has been noticed that these grubs can bear a cold which freezes their juices.

The perfect insect is of a very dark grey, having a long beak and ten narrow lines along the wing-cases; it only measures an eighth of an inch. Having quitted the ground, after a little while the females re-enter it to place eggs upon the roots of the Cabbage; to mix into the surface soil such substances as gas-lime or soot is, therefore, likely to have a deterrent effect upon them. The common practice of leaving about in heaps the stumps of Cabbages with roots attached has helped to multiply this weevil, which, where its maggots are numerous, weakens the plants, though it seldom destroys them. Young Savoy, it should be added, sometimes have their rootlets attacked by the maggot of a small fly, *Chortophila floccosa*, which nibbles these until the plants perish from exhaustion. And, lastly, we may in some seasons find ants crowding upon young Cabbages. What harm they do we cannot exactly say, but it is just as well to clear them off, as for instance by well watering with a decoction of quassia.—ENTOMOLOGIST.

THE INDIGO PLANT (*INDIGOFERA TINCTORIA*)

THE uncertainty of the indigo crop is as proverbial as that from the Hop plants in England. In Bengal the crop is particularly subject to be

Fig. 78.

destroyed by the annual inundation of the river, if it occurs earlier than usual. A storm of wind, accompanied by rain and hail, as completely ruins the crop as if devoured by the locust; neither from this latter scourge is the crop exempt.

This proneness to injury extends throughout its growth. The seedlings are liable to be destroyed by an insect closely resembling the Turnip fly, as well as by the frog. Caterpillars feed upon the leaves of older plants, and the white ant destroys them by consuming their roots.

To these destructive visitations may be added the more than ordinary liability of the plant to injury, not merely from atmospheric commotions, but even from apparently less inimical visitations. Thus, not only do storms of wind, heavy rains, and hail destroy the indigo planter's prospects, but even sunshine, if it pours out fervently after showers of rain, is apt to scorch the plants; and if it occurs during the first month of their growth is most injurious to their future advance. The reason of this effect appears to be the violent change from a state of imbibing to rapid transpiration of moisture.

The *Indigofera tinctoria* belongs to the natural order Leguminosæ. Its leaves are pinnate, its stem shrubby and erect; its flowers in racemes are pale with a red keel and vexillum.

VALLOTA PURPUREA.

As an autumn-flowering plant I think *Vallota purpurea* ranks amongst the best of our greenhouse-flowering plants. Several came into bloom in the middle of September, and have lasted to the present time. I find them more useful at the time above-mentioned than in the beginning of August, and they last twice as long. It is a mistake to over-pot them, and the drying system practised by some gardeners is wrong. The *Vallota* is an evergreen bulb, and must never be allowed to get dry at the roots. My plan is to pot in March three fair-sized bulbs into 8-inch pots, the compost to consist of strong loam, a sprinkling of sand, and as a manure I think there is nothing to surpass sheep manure and a little soot. I keep the plants in a shady part of the greenhouse after potting till the end of May, when they may be shifted into a cool frame fully exposed to the sun. They require an occasional watering with liquid manure. I find plants potted in late autumn come in bloom earlier than those potted in spring.—W. ROBERTS, *Llynghuarn, Machynlleth*.

NEW HOUSES AT CLEVERLEY, ALLERTON.

In the gardens of T. Sutton Timmis, Esq., Allerton, can be seen one of the most compact and convenient ranges of glass houses that it is possible to find in any garden about Liverpool or probably anywhere else. The houses in question have only recently been erected, and therefore are not yet thoroughly furnished with plants, but it is not my intention to note many particulars about these, but certain arrangements in the construction of the houses demand notice.

Several horticultural builders were invited to furnish designs, and the one selected as the most suitable was the work of Mr. T. Hill, Woolton, to whom the construction of the houses were entrusted. The houses are all built in a block and are twelve in number, nine of which lead out from a lean-to corridor 120 feet in length. This allows of the whole of these houses being passed through without going outside. Eight of the houses leading out of the corridor are span-roofed, the other one being a lean-to and built to fill up a rather peculiar corner against the end wall, which if left would in some measure have destroyed the finished appearance which these houses now present. Four houses on the west side are devoted to plants, and these are longer than the remainder, which are utilised for fruit. The remaining three houses run parallel with the corridor and at the ends of the fruit houses; these are span-roofed structures about 20 feet long each by 12 feet wide. These are built for Cucumbers, Melons, and Tomatoes; good crops of the latter were hanging in one of the houses. Winter Cucumbers filled the second, some good *Calanthes* and *Nepenthes* the third. Amongst the latter *N. Mastersiana* was very noticeable.

The front entrance is on the west side and in full view of the mansion, but some distance away; in fact, this entrance is arranged to face a walk that leads from this portion of the ground to the mansion and pleasure grounds. The entrance to the houses is very neat, and opens into a very comfortable little apartment furnished with seats and chairs, also a few suitable plants and climbers which are intended to furnish the sides and roof. The house to the right of the centre upon entering is for Azaleas and other greenhouse plants, while the one joining the corridor has the centre filled with *Camellias*. Beds are arranged on each side, *Lapagerias* being planted on the shady side and *Roses* on the other. The wall end of this house is also planted with *Camellias* and other suitable wall plants. Round the sides narrow stages will eventually be erected. In these, as well as the two following houses, the doors are 3 feet 6 inches wide, and the space can be made 20 inches wider by a simple arrangement, so that large plants can be passed in and out without fear of injury. On each side of the door is a wide sash which, on the opposite side to that the door is hinged to, is arranged to open the same way as the door, while the doorpost can be removed by drawing a small brass bolt and then lifting it out of the way. This then leaves an open space of 5 feet 2 inches, through which very large plants can be passed. This is decidedly the best arrangement of the kind I have seen, and exhibitors of large plants intending to erect houses would do well to make a note of it.

The two next houses are devoted to stove plants. The first will be maintained at stove heat proper, in the other at an intermediate temperature. This is arranged so that stove-flowering plants while in bloom can be placed in the cooler house of the two, where they will last double the length of time as would be the case in the close moist atmosphere of the hothouse. Several good *Crotons*, *Stephanotis floribunda*, *Allamandas*, *Anthurium Andreanum*, and *A. Scherzerianum* are already occupants of these houses. The last plant named is a magnificent one, more than a yard through, and has been grown by Mr. Cromwell, the able gardener, since it had four leaves, but not in these gardens, for when his previous employer died the plants were disposed of, and the one in question at the sale became the property of his present liberal employer. In these houses one or two arrangements demand notice, the first being the floor, which is formed by neat cast iron gratings resting in a framework of stone or cement. Beneath these gratings the bottom and sides are cemented so as to form a shallow tank. These can be kept full of water when desired or emptied at will by lifting a plug, and the water passes into the drains. This is a capital idea, as plenty of moisture can be maintained in the atmosphere of the house by water under the gratings without the floor being wet, which renders stoves in the majority of gardens so objectionable to ladies. Round the side stages of both these houses a tray about 4 inches deep and probably 6 inches wide is provided of ironwork, in which small plants are now plunged amongst coco-nut fibre refuse in 3 and 4-inch pots for purposes of decoration. Holes are made in the bottom for all surplus water to pass away. Something of this kind is wanted in the majority of plant houses where effective arrangements are required and where the houses are required to be made as attractive as possible. Trays of this description planted with *Selaginellas*, *Panicum variegatum*, small *Ferns*, *Begonias*, *Fittionias*, and other small-growing flowering and foliage plants would present in contrast a much more beautiful and natural appearance at the front of a bank of plants than if the same varieties were arranged in pots. Few plants for edging purposes look better together than *Panicum variegatum* and *Selaginella caesia*, both of which would reach to the walk in a very short space of time, and nothing could possibly give a

more charming appearance to the sides of the houses. The plant houses are each about 36 feet long by 20 feet wide, and are somewhat higher than those devoted to fruit.

The vineries, four in number, two in each range, are about 25 feet long and the same width as the plant houses. The first in the range is planted with Black Hamburgs, the second with Alicantes and Lady Downe's, the next range Muscat of Alexandria, and eventually the other house with Madresfield Court, being now occupied with Peach trees. The Vines were all planted last spring, and have made capital growth. The borders are being made on the piecemeal system, and all are inside, no provision being made for outside borders. These as well as the plant houses are well supplied with water, and arrangement has been made for a good command of warm water from the hot-water pipes.

The last house from the corridor is entered by descending one step, the only one in the whole block of houses. Although this is rather a peculiar shaped house it is a very pretty one. The wall on the side next the vineries is covered with *Selaginella Kraussiana* (denticulata). The stage on the opposite side is formed by rockwork made of sandstone, very tastefully arranged and planted with *Ferns*. Two tanks are displayed in the rock-work, and add materially to its appearance; standing just above the water in one was a fine pan of *Trichomanes radicans*. The back wall is planted with *Adiantum cuneatum*, and the stage is being filled with cool *Orchids*, and those already occupying the house are making strong, vigorous growth, and should do well in this house.

The corridor has a walk 5 feet wide, formed of tiles its full length, with a border 2 or more feet wide at the back, in which a collection of climbing plants are planted out to furnish the wall and roof; these will be interesting and effective when they furnish the space allotted to them. The wall has been very attractive with *Tropeolum Jarratti*, which has been freely planted to impart a brightness to this place until other plants are established. On the border a number of flowering plants in variety are arranged, and also on a narrow stage on the front between the ends of the other houses. Beneath the stage *Ferns* and *Mosses* are planted. *Roses* have been freely planted, and the whole have made remarkably luxuriant growth.

The stages in the houses are all formed of iron and three-quarter-inch slates, and have a very light yet durable appearance. The houses are well wired; in fact, the whole of the ironwork and heating arrangements are as complete and well finished as it is possible to have them. This work was entrusted to Mr. Joseph Bramham, 104, Wall Street, Liverpool, and knowing his ability and experience, I should have been surprised to find them in any other condition. The whole of the houses are heated by two of Mr. Bramham's improved saddle boilers with waterway back, and Mr. Cromwell spoke most highly of the heating power of these boilers. If I remember rightly there is no less than 10,000 feet of 4-inch piping to these boilers. The main pipes to the other houses are utilised for heating the corridor and the cool *Orchid* house, for the mains pass through it to the *Cucumber* and *Melon* houses. The heat for this house and the corridor rise through gratings arranged in the walk or under the front stage. The openings are fitted with zinc below the gratings so as to keep down the whole of the heat when not required. This is very good, for no heat is wasted in chambers outside, for all the pipes are inside the houses except a small length that just crosses the walk to the *Cucumber* houses; but this is not for more than two or three yards at the most.

The space between all the houses and a good walk the entire length of the range has been concreted and cemented, so that it can be washed down and kept perfectly clean. From this end all the rough work, such as wheeling soil for the *Vine* borders, *Cucumbers*, and *Melons*, &c., is done to save passing through the corridor. In fact, this is the most convenient, for the outer walk terminates in a back road just behind the boundary wall.

The potting and packing sheds are behind the corridor, also the gardener's office; in fact, the corridor leans against the wall of these buildings. Plenty of room is allowed, and the one follows the other in rotation, the packing shed being in the centre of the corridor, and opens into it, so that plants or flowers can be brought from the house to the various sheds during all weathers without passing outside. The boiler house is just below the packing shed, and receives a certain amount of light from that structure. The stokehole is rather dark, but it is in a most convenient position, and is entered on the outer side of these buildings. Plenty of gas is provided in the stokehole, and this abundantly makes up for the deficiency of natural light. The sheds are lighted and ventilated from the top so as not to destroy the uniformity of the outer wall, which corresponds with the stables and stable yard. The stables are enclosed at the end by large, wide, massive doors, and an equally substantial building was being erected on the opposite side for wheelbarrows and other implements. To the front of the houses is a capital square of ground that was being converted into a plunging and standing ground for plants.

The kitchen and fruit garden, as well as the pleasure grounds, although not extensive, were in excellent condition. Taking this place altogether, it is the neatest and most compact that I have had the pleasure of visiting for a long time.

In conclusion, I have to say that great credit is due both to Mr. Hill and Mr. Bramham, and the very highest commendation is due to Mr. Cromwell, the able gardener, for the many valuable instructions imparted by him during the construction of the houses and the other work that has been so well carried out.—WM. BARDNEY.

KITCHEN GARDEN.

AUTUMN-SOWN PEAS AND BEANS.—Where these are just peeping through the soil dust them every other day in wet weather with powdered

lime or soot. Birds, snails, or other pests may eat the points of the young plants before anyone is aware of it. When they are fairly up sift some powdered ashes and put a thick strip of these along each side of the plants. Few snails or slugs will venture over to the plants then, and we have sometimes thought they succeeded better with the ashes around them than soil. Probably the ashes are drier and warmer. Where it was neglected to sow Peas in November they may still be put in, giving them rich soil and a warm dry situation.

TOMATOES.—Our old plants have been all cleared out, the green fruits have been cut and hung in a warm house to ripen, and these will keep up a supply till the new year. Cuttings in pots should be kept in a cool house and near the glass. Protect them from frost, and they may be potted and placed in more heat as soon as the turn of the year comes. Those who have not provided a stock of plants from cuttings and wish to begin with a hatch of plants early in January should sow seed at once. Fill a number of 3-inch pots with rich soil, make a little hole in the centre of the soil with the forefinger, drop two seeds into each, cover them, place them in a temperature of 60°, do not water the soil until the plants are seen, which will be in a week or so after sowing, and by the first or second week in January there will be plenty of young Tomato plants. The object of putting two seeds into each is in case of failure, and when both grow one should be pulled up when quite small. Much sturdier plants are produced in this way than when they are raised in a crowd and transplanted afterwards.

FORCING SEAKALE.—The flavour of Seakale is always very much influenced by the way in which it is forced. Sometimes it tastes very strongly of manure. Some of the finest flavoured produce we ever secured of it at this season was forced in the following manner: The rows were 3 feet apart, and the soil to the width of 18 inches was dug out from the vacant space between the rows and hanked up over the crowns of the plants in much the same way as Celery is earthed. The trenches were a little over 1 foot in depth, and they were filled up level with the top of the ridge with hot manure. This soon induced the growths to push forth strongly, and the soil which they were growing in, and had been put on the top, blanched them well. This is a simple way of growing Seakale at this season, and it is very satisfactory when the main point is considered—viz., flavour.

ASPARAGUS.—We find the roots of this force very freely this autumn. The crowns were well matured, and the produce is very fine. Those who have been waiting to give the roots a good rest before forcing may begin at once with every certainty of securing a good return if their roots are strong and healthy.

RHUBARB.—This may also be introduced to the forcing quarters in quantity, and if it is forced where it has been growing by putting empty casks upside down over the crowns and covering with a hothed, see that there is plenty of ventilation at the top of the cask to allow the steam to escape, as if this is confined it will cause the young growths to decay and there will be no Rhubarb.

MUSHROOMS FROM COW MANURE.—It may interest many who are sometimes in a fix to understand what to make Mushroom beds with that cow manure may be used successfully. Not far from where we write a large bed was formed two months ago with cow droppings and short straw from the cowshed, and for some time past this bed has been supplying Mushrooms which in size, colour, or flavour were all that could be desired.

SPINACH.—Any of this with large succulent leaves is sure to suffer if severe frost comes, and our plan is to use as much of it at present as possible and save the more hardy vegetables for further on. We have sometimes had better winter Spinach than we are using just now, as the very dry weather experienced when the seed was sown and the young plants were coming up, checked them so much that they still bear traces of it. Some may be inclined to allow such crops as this to become weedy under the impression that this is protection, but it only ruins the plants.

OLD CROPS.—Many of these may now be cleared from the ground. The whole of our Carrot ground has been cleared and dug roughly up. Beetroots have been all stored and the ground dug. All the autumn Cauliflower stumps have been cleared off, and the land limed and dug over very roughly. Should the weather remain open for another week every particle of vacant land in our garden will have been rough-dug, and should frost come on later, as it is almost sure to do, its mellowing influence will be very advantageous.

FRUIT FORCING.

FIGS.—Earliest-forced Trees in Pots.—The trees in houses closed in November with fermenting leaves in the pits will now be showing signs of growth by the swelling of the terminal buds, and the gradual bursting forth of the embryo fruit. The roots that were cut back will also, under the influence of the genial heat obtained from the fermenting material, be sending fresh feeders through the new compost placed about the pots. When this is the case the fermenting materials should be examined, and if the heat does not exceed 75° they may be trodden down round the pedestals and bases of the pots, preparatory to the introduction of a fresh supply from the reserve heap, which should be under a roof of some kind. At any rate, all materials used for bottom heat or plunging purposes should be properly worked and warmed before being taken in. Take care that the heat about the pots does not exceed 70° to 75°. The heat and moisture given off by the fermenting materials will greatly facilitate forcing operations by softening and greatly reducing the amount of fire heat, until we have a change to milder nights. The external temperature will have much to do with the internal temperature. On cold nights it should fall to 50°, and 55° by artificial means in the daytime will

be sufficient, with a rise of 10° from sun heat. Syringe the trees and walls with tepid water on fine mornings, and again early in the afternoon or about 2 P.M., but with the moisture arising from the fermenting materials there will rarely be need of more until the trees begin to push fresh foliage. Keep the glass clean and free from condensed moisture by ventilating on all favourable occasions.

Succession Houses.—If the pruning is still in arrear, lose no time in getting the work finished. Cut back or entirely remove old spurs, and thin out the least promising shoots that have reached the extremity of the trellis, to make room for free growth and full development of wood and foliage. As the Fig delights in heat, moisture, and good living, with plenty of light and a free circulation of air, the house should be well heated, be light and well ventilated, and generous treatment accorded, otherwise it is the most insipid of fruits. Thorough cleanliness is necessary to success, therefore spare no pains in cleansing the trees, woodwork, and walls, and paint if necessary. If brown scale has been troublesome syringe with petroleum at the rate of a wineglass to three galleons of water, keeping it well mixed with the water whilst it is being applied. If applied with a brush it may be applied much stronger, or at the rate of a wineglass to a gallon of water, at which strength it will destroy all insects it comes in contact with.

CUCUMBERS.—The night temperature should be kept steady at 60° to 65°, and the day at 70° to 75°, being very careful in the admission of air, though a little should be given so as to clear the glass of condensed moisture, and give the plants the benefit of all the light possible, condensed moisture obstructing the light to a serious extent. It is hardly necessary to point to the desirability of keeping the temperature from being unduly lowered by frequent opening of the door, as is frequently done several times a day in severe weather, and which could be obviated by having the thermometer in such position that it can be seen from outside. A mat suspended over the door is also useful in preventing an inrush of cold when the door is opened. Remove all superfluous fruits from the plants immediately they show, and tie up all shoots to the trellis as they require it. Encourage vigorous growth, on which stopping should be moderately practised, otherwise very little stopping will now be required. Should mildew appear dust the affected leaves with flowers of sulphur, and maintain a somewhat dry atmosphere. For red spider sponge with softsoapy water, and if green or black aphides attack the plants dust with tobacco powder, or if fumigation be resorted to it must be done with great care and judgment.

Prepare some Oak or Beech leaves with a third of stable dung by throwing into a heap and damping if necessary, turning over when they have become warmed through outside to inside, and watering if necessary so as to secure an even and thorough fermentation of the materials, with which to make a hothed at the end of this or the beginning of the new year, to raise Cucumber and Melon plants from seed, and subsequently to make beds for planting them in.

PEACHES AND NECTARINES.—Earliest-forced House.—The blossom buds will now be swelling, the trees having been given the treatment advised in our last calendar, the temperature should be slightly increased in the daytime, especially when the weather is mild or marking 50° outside with a soft wind blowing. The heat should be turned on in the morning, so as to raise the temperature to 55°, and allow a rather free circulation of air, and with sun the temperature may rise to 60° or 65°. The heat should be turned off at night, so as to allow the temperature to fall to between 45° and 50°, and on cold nights it may fall 5° lower without any disadvantage. Avoid a dry atmosphere, especially from fire heat; gentle syringing the trees backwards and forwards with tepid water is of great benefit. If fermenting materials have been introduced a little extra attention should be given them in turning and additions which will impart activity to the surface roots. Give attention to the roots, and if at all dry a good application of tepid water will render the soil thoroughly moist. If the soil has left the walls, as it sometimes does during the resting period, it should be well rammed down, so as to make the water enter by the surface, otherwise it will run off without permeating the soil.

Succession Houses.—Complete the pruning and cleansing in houses intended to be closed for forcing soon or at the new year. Lay in the wood sufficiently thin to admit of the full development of the foliage, as fine fruit of good colour and flavour cannot be obtained where the young wood and leaves are deprived of the benefit of air and light. Keep all doors and ventilators open in all but actual frost; even this will not do any harm, but structures of this kind are often filled with plants, and in the anxiety to save these the lights are frequently closed when they should be open, and imperceptibly, but surely, the blossom buds swell, the idea of serving two masters being that neither do well—the plants are starved, and yet not starved enough to insure perfect rest to the trees, so that between alternate excitement and its opposite they receive a check, and if the trees do not cast the buds the blossom is weak, and sets very badly. It would be much better to have the roof-lights off altogether, and keep them off until the time arrives for closing the house. No frost will injure the trees provided the wood is ripe.

PLANT HOUSES.

Amaryllises.—Few plants are more useful for decoration than these, and when in flower they are most effective when their large brilliantly coloured flowers are elevated well above dwarf flowering plants. The habit of these plants and their slender flower stems render them most suitable for this purpose, and a few with variously coloured flowers add a choiceness and beauty to a collection of flowering plants which they

would not otherwise possess. They can easily be brought into flower during the dreary months of winter, and are therefore doubly valuable. A few well-ripened flowering bulbs that have enjoyed a good season of complete rest should now be started in a temperature of 55° to 60°, which will soon induce the flower spike to make its appearance from the side of the bulbs. If the atmosphere into which they are introduced is moderately moist no water need be given them for the first few days or a week, and then the dry soil may be thoroughly soaked with tepid water. After all superfluous water has drained from the soil plunge the pots in sawdust, cocoa-nut fibre refuse, or any similar material, to prevent having to supply water again until the plants are ready for removal to the structure where they are to be arranged while in flower. Where an annual system of potting is adopted the old dry soil may be carefully removed from their roots, which should be perfectly fresh if ripened off gradually and properly, and the bulbs in clean pots in a compost of fibry loam, one-seventh of decayed manure, and a liberal dash of coarse sand. If the soil is in a suitable condition for moisture when they are potted no water at their roots will be needed before they come into flower if the pots are plunged and the surface of the soil covered with the plunging material to prevent evaporation. By the time the plants unfold their flowers the roots will be active and working freely amongst the new soil, and if properly treated after flowering luxuriant growth will follow.

Gesneras and Tydas.—These plants will be very useful presently, and in order to retain the beautiful foliage of the former in good condition they must be arranged close to the glass in an atmosphere that is not too moist, or else the foliage will be liable to damp. Care must also be taken that no water, either through watering or the syringe, shall fall upon them, or their foliage will be browned and disfigured. These plants will do admirably on a shelf until they come into flower where the night temperature ranges about 60°. Where some of the earlier-flowering varieties are grown and have ceased flowering they must not be neglected, or the tubers will suffer, and instead of being strong and large for another year they will only be small and weak. They should be as carefully watered until the foliage naturally dies as those that have yet to flower; they should also be retained in a similar temperature. These plants are not unfrequently ruined by neglect after they have flowered. *Gesnera tubiflora* is a grand old plant but very seldom met with in gardening establishments; it is, however, worth a place in every garden, however choice or limited the collection of plants grown may be. It requires early in the season an intermediate temperature, but during summer will do most satisfactorily in a cool greenhouse or the conservatory. This flowers during summer, and is of slender growth, which attains a height of from 2 to 3 feet, and towards the extremity of the slender stem the flowers are produced which are of the purest white, tubular in shape, nearly 4 inches long, and most deliciously scented. It is a very effective plant for the conservatory during the summer, and the flowers individually are useful for bouquet-making. This variety forms tubers which very much resemble Potatoes, and can while at rest be stored away the same as other varieties. In addition to propagation by the tubers, side shoots which are freely produced from the axils of the leaves root freely, and if rooted early in the season form capital tubers in one season. Some of the tubers of this species may now be cleared of the old dry soil and repotted in fresh compost; this kind does not appear very particular about soil. If the plants are to be grown singly 5-inch pots are the most suitable for them, and they are more effective this way than when several tubers are grown together in one pot. Plunge the pots as advised for *Amaryllis* until the plants commence growing, then give them an intermediate temperature for a time.

Achimenes and Gloxinias.—Where a display of the former are required as early in the season as possible the tubers should now be sorted from amongst the old dry soil in which they have been rested. When this has been done they should be laid into pans or pots amongst light sandy soil, and placed in a temperature of 60°. If the soil used is moderately moist when the pans are filled, and they are afterwards plunged, no water will be needed until growth commences. Care, however, must be taken that the soil in which they are placed does not become dry, or they will not start freely into growth. If the soil approaches a dry state tepid water must be given, but this will not be needed if the plunging material is kept moderately moist. All that are not yet wanted for starting may be selected from amongst the soil in which they grew last year, and be laid amongst sand ready for starting at any time when needed. Where the system of raising pots and pans of these plants by cuttings is adopted the tubers may be started into growth amongst the old soil after it has been well soaked with water. *Gloxinias* should also be started for early flowering. These should be turned out of the pots in which they were grown last season and placed in boxes or pans thickly together amongst leaf mould until they commence growing. These should be placed in the same temperature as the *Achimenes*, and be kept moderately moist by syringing the surface. As soon as they have fairly started into growth they should be potted singly into 5 and 6-inch pots, or larger, according to the size of each tuber.

a lucid description of the wax-extractor, and points out the various uses to which it may be put. As the extractor I use is somewhat different from his, perhaps I may be allowed to describe, the main difference being a pipe in the centre of the upper division, which leads into a perforated tube in the tin sieve reaching about two-thirds up. By this addition the wax is extracted much quicker and more thoroughly than when the steam passes from the generator by the sides only. My extractor measures 1 foot 6 inches by 1 foot 3 inches, and the sieve is over a foot in diameter. The steam generator we use for many purposes, and could not do well without it in making comb foundation. Copper or brass would be more lasting and better for some purposes than tin.

After the steam is up and the sieve full of rich combs, should occupy not more than fifteen minutes to thoroughly drain, producing about 5 lbs. of wax each fill. When the wax has been run off it should be re-melted, and in all cases of liquefaction should be melted in double-sided vessels, glue-pot fashion, as boiling spoils wax. When a fine sample of wax is wanted the slower it is melted and the longer it is in cooling the better, all impurities getting time to settle. If the wax is melted in a cone-shaped vessel, then the impurities cover less surface and can be cleared away with less waste than when the surface is broad. For many purposes the wax so moulded requires nothing more; but where cakes of a certain size are wanted, it must be melted again, and poured into moulds of a size and shape preferred, previously well soaked in water, but on no account should soap, soda, or any grease be used; a very small portion of soap spoils much wax, while soda makes it brittle. When wax has been once spoiled by any of these ingredients no after operation will restore its flexible properties.

So far as my experience goes, no sample of foreign wax is equal to our native wax for any purpose, and realises a much higher price in the market—1s. 8d. to 2s. per lb. is offered and readily got for all samples of genuine Scotch wax. It is frequently asserted that wax does not deteriorate by being long kept in the comb state. This is a mistake; it both diminishes in quantity and deteriorates in quality, so the sooner wax is extracted after the combs are removed from the hive the better, and for that purpose it is advisable to have a little extractor, so that all scraps of comb be forthwith melted, thereby saving both wax and preventing an increase of moths.

PRODUCTION OF WAX.

I fully expected to have been able to give an accurate statement of the amount of honey required to produce a pound of wax, but an accident befel the bees I was experimenting with, so for a time I have been frustrated. But it is perhaps worth while to record the following, and it is but one of many cases that can be cited. From the combs of three "Pettigrew" straw hives 6½ lbs. was extracted. Now the bees from these hives were fed with 23 lbs. of sugar, and the hives are filled with combs, and have seemingly as much syrup as will tide the bees over till spring. But suppose each swarm carried off 2 lbs. of honey when being driven, the total would not exceed 25 lbs.; but even with this quantity, and supposing 15 lbs. is stored for winter use, 10 lbs. is all that has been consumed to form same quantity combs that fully 2 lbs. of wax has been extracted from. This at a time when we hear it prophesied that honey must be sold at 3d. per lb. is a momentous question, because if 5 lbs. of honey produce 1 lb. of wax at the present current prices, it will pay better to produce wax than honey, and thereby save all expensive packages and carriage, but it is worth while for bee-keepers to make a thorough test how much honey is required to produce a pound of wax. We are quite prepared to meet the inevitable fall in the price of honey consequent on the increasing numbers of bee-keepers, but I feel certain that so low a figure as 3d. will never be accepted by the fraternity. A combination of the bee-keepers, and the superiority of British honey over foreign, will avert any such calamity. Just as we see foreign Grapes selling at 4d. per lb., while home-raised

THE BEE-KEEPER.

NOTES ON BEES.

WAX-EXTRACTOR.

At page 481, your esteemed correspondent "Felix" gives

ones are selling at 2s. 6d., so will home honey keep the ascendancy over any foreign samples we have ever tasted.

PACKAGES FOR HONEY.

These seem to be attracting the attention of both bee-keepers and manufacturers, and while I agree with "Felix" on the point of utility I am inclined to think crystal ornaments might become too numerous in the house. We want people to consume many pounds of honey annually; we also want something very light and unbreakable. Tin has these properties; but irrespective of what scientists say, the observant housewife discovers that where honey is stored in tins there is always some of it offensive-looking close to the tin, which to eat would be folly. Glass is clean and pretty-looking, but is heavy and brittle. I do not put the same value upon the elegant package as many do. I have often thought of convenient light and cheap packages, but could never fix on one that would be approved of. Skins of various sorts I have thought of, but I have never been able to reconcile myself to them when associated with honey. I contrived a honey sack of common calico waterproofed and lined inside with white paper firmly attached to the cloth by a special paste; into this bag I put the honey, tied it, and found that it answered the purpose well, especially that of sending honey cheaply to a distance. The above description will perhaps induce some one to improve on it, and send out a really useful flexible sack.

RACES OF BEES.

I am sorry I am unable to give an accurate comparison of the different races of bees in one apiary, and under the same conditions, because the pure black bees have in many places disappeared. It is only when at the Heather that comparison can be made. The crossed Cyprians have this year again surpassed everything. Twenty-five pounds (what was believed to be common bees) was the highest make, but the crossed Cyprians rose 40 lbs. This weight was attained by all of that strain. The more remarkable because two of these stocks belonged to different persons to whom I gave queens last year.

One stock of my own that swarmed late in June gave me the highest yield, while its swarm, though three weeks behind others, weighed, bees, honey, and combs, 100 lbs. nett. The Carniolians came hard behind, and perhaps would have equalled, if not surpassed, had they been on same footing at the start. It is now eight years since I had these Cyprians from Mr. A. Neighbour, and they have always excelled. Through ill health I lost both my first imported Syrians, as well as the later imported Cyprians, which prevented me proving earlier their character and good points; but the past summer afforded me ample opportunity of testing the temper of the Syrians, and the autumn brought proof of their eagerness to breed and work. So late as November 25th I observed them collecting water, and although through the lateness of my Syrian stock I had not the opportunity of determining their honey-collecting powers during the height of the season, yet I found nuclei gathered in proportion equal, if not more, than hives of supposed natives. As I have some half a dozen stocks of Syrians in excellent condition, and judging from their anxiety to work, I am in hopes that they will prove themselves excellent honey-gatherers, but I expect a tussle with them on the score of robbing and stinging. They are perfectly harmless when left alone, but interfere with them it requires a steady nerve to handle them. This spirit appears to make them a formidable foe to all vermin about the hive. The earwig that associated itself so much with the common bee dare not venture near a Syrian. While manipulating a hive lately the earwigs ran all about, but none preferred to enter the hive. One I observed at the corner of the alighting board eyed the bees with a thievish suspicion, turned, and fled. Another, less lucky, stood in the run of the bees. One flew out, and without a seeming slackening of speed, picked it up and flew off with it.

CALMING BEES.

The most satisfactory way of calming vicious bees is to keep strangers from the apiary. Frequently they are attacked and stung, which aggravates the bees the more. Be familiar with them, and if any attempt to sting turn calmly aside, but immediately return to the hive. Let them feel your presence by touching the hive cautiously and gently. If the bees rush out a little carbolic acid will cause them to retreat, when more freedom may be used, which should be repeated at intervals until they are subdued. I never failed in subduing the most spiteful hive by this treatment if I except the Syrians.

COTTAGE BEE-KEEPERS.

I quite agree with the remarks by "Felix" on cottage bee-keepers, but with all the cottager has to contend against he will survive the longest. It is the true lover of Nature that is really the bee-keeper, and will keep bees for nothing but the love of them. The mercenary bee-keeper will sooner or later go to the wall. There are hundreds of cottager bee-keepers who thoroughly understand apiculture yet cannot explain it by writing, and could not even take a third-class certificate at the examination of the British Bee-keepers' Association, yet could give any of its first-class experts a salutary lesson in the art, as has been their wont. The true bee-keeper is not only a lover of Nature but is also a true lover of his fellow creature, and it is my lot to be acquainted with gentlemen bee-keepers whose bees do not only give him much pleasure, but many a poor invalid shares with him the bee treasures.—A LANARKSHIRE BEE-KEEPER.

THE BLIGH COMPETITION.

WHAT HAS IT PROVED TO BEE-KEEPERS?

THIS scheme originated with the Hon. and Rev. H. Bligh offering in November, 1881, a prize of £10 to that bee-keeper who could show the greatest nett profit in bee-keeping from a capital of £2, so as to be able to show cottagers what the modern system of bee-keeping would do for them. The idea was favourably received, the £10 increased to £20, divided into six prizes, but the promoters made it a condition that only members of the British Bee-keepers' Association, or of county associations in affiliation with it, were to be allowed to compete, thus showing their anxiety (?) at the outset to get hold of the most profitable system.

Only experts were requested to compete, of which seventeen entered, including Mr. C. N. Abbott, who, with nine others, failed to show at the finish; only three out of the remaining seven kept within the limit of £2, the first prize going to a committee member of the B.B.K.A., who helped to select the judges, and exceeded rule 6 (which limited the outlay to £2) by £1 7s. 4d., while another one made nearly double the amount of profit, whom they disqualified for breaking rule 6, though the published diaries do not show that he did so more than others. It appears also that the first prizeman inspected his apiary on behalf of the B.B.K.A. in his absence, and thus saw what he was doing. When he saw that he was thrown over he claimed the first prize through his solicitor, when the Committee, composed of the first prizeman and two of the judges, passed the following resolution—"Resolved unanimously, That the Committee, having appointed judges to award the prizes in the Bligh Competition, and having no reason to doubt either their competency or integrity, regard their decision as final."

In the same issue of the "B. B. J." which reports the above, is a letter from one of the judges, who says—"Rule 6 certainly was improperly worded, and we must ask pardon of those competitors who were misled, and thus, perhaps, kept back from a higher place in the prize list." A correspondent had asked, as there was to be another one, for the proposed rules to be submitted for criticism, so as to have them perfect, as what was the use of rules if not enforced on all alike? This, however, was never done, though the Editor of the "B. B. J." for October 15th, says—"The rules were again considered by the Committee, and subjected to public criticism. Various suggestions were made, and several improvements were proposed and accepted." I challenge him to prove where the slightest alteration was made in the rules, though they received the condemnation of all intelligent persons. I had intended entering myself, and working skep and frame hives in combination, had the rules allowed me to do so. However, thirty-three entries were made, of which number only nine have turned up at the finish. Of course these show a most wonderful profit account. Remember they had two good summers, and only a mild and dry winter between; but comb honey is valued at 1s. 6d. per pound, and each section called a pound whether it contains ten, eleven, twelve, fourteen, or sixteen ounces of honey; extracted 1s. 1d. per pound, and bees 4s. even at the end of August, when they can be bought at 1s. per pound, and nothing deducted for time or labour, although rule 5 says the time occupied at each visit to the apiary shall be recorded. If this has been done the Judges have carefully withheld it from the public, as no trace of it is in any of the accounts. These

nine out of thirty-three started on May 20th, 1884, with 30 lbs. 12 ozs. of bees, hived on foundation in frame hives averaging 3 lbs. 6½ ozs., each. At the end of 1884 they had been increased to twelve lots, and collected in comb and extracted honey 306½ lbs., comb honey not weighed, averaging for the nine swarms 34 lbs. each, which at 8d. per lb., the top price offered by the Reading Depot for comb honey, gives a return of 22s. 8d. each. On August 31st, 1885, they had increased to nineteen, and gathered this year 864 lbs. of honey (comb honey again not weighed), or an average of nineteen hives of 45½ lbs., which at 5d. per lb., the average nett amount given by the British Honey Company for comb honey, gives an average return of 18s. per hive. From these figures must be deducted the value of the bee-keeper's time employed, sugar used, and the average risk of loss—which, considering over two-thirds fell out, presumably because they had lost their bees, and all expert bee-keepers, mind, must be considerable—to be able to see what the nett profit is on bee-keeping as a business, but as the Judges and the "B. B. J." have given no particulars whatever for last year and most imperfect ones possible for this, of course I cannot tell. For instance, foundation, sugar, &c., 10s. 2½d., no particulars of the quantities, or how used, or what the &c. consisted of. The accounts, as placed before the public give me the impression that they have been shown to prevent the public from criticising the Judges' decisions, and prevent unpleasant demands for the first prize by those put out in the cold.

There is one remarkable passage in the "B. B. J." for October 15th last which I wish to draw public attention to, which is as follows:—"The nine swarms, which weighed in the aggregate 30½ lbs., have, during the fifteen months of the competition, collected no less than 1170 lbs. of honey, or an average of 130 lbs. per swarm." The Editor then goes on to value this at 9d. per lb., and makes a return of £4 17s. 6d. per swarm. Now could anything be more misleading than this? First, to call two whole seasons "fifteen months," then nineteen stocks "nine swarms," and imply two seasons' produce from these as one year's from nine! I think he is "hard up" for an argument to prove the lucrativeness of his system of bee-keeping when he has to do this. On the same lines of reasoning a man who started twenty years ago with a hive which has increased to fifty, might just as well calculate his honey returns as produced from his first one hive, and as the Editor of the "B. B. J." has several times boasted of taking from 200 to 300 lbs. of honey from a swarm of bees it is only natural to think now he got it from a large number of colonies, the offspring of one swarm, and probably spread over a number of years. If this is not so, let him explain.

In conclusion, I submit that the past "Bligh competition" has proved nothing more than that the B.B.K.A. are incompetent to carry out a grand educational and statistical idea, and that the modern bar-frame system of bee-keeping is not so profitable to the average bee-keeper, to say nothing of cottagers, as its advocates would have us believe. I do not think one in fifty, either in this country or America, has made it pay, while only one in a thousand has made great profits, and these are held up as "haits" by those interested in selling bee-keepers' supplies to draw others in, and I assert that the only class who make much profit in bee-keeping are the supply and honey dealers. Though these keep a few bees to sell, I do not know of one keeping bees to raise honey for the markets.

Things may come right in a while, but the prospect is gloomy for honey producers at present.—A HALLAMSHIRE BEE-KEEPER.

FRAME AND STEWARTON HIVES.

I WISH to make two bee hives, and should feel obliged if "A Lanarkshire Bee-keeper" would tell me what is the difference between a bar-frame hive and one of the Stewarton hives. I have only seen one wooden hive since I commenced bee-keeping; it was said to be a Stewarton hive. It consisted of four boxes, two of 6 inches deep and two of 4 inches deep, the 6-inch boxes for breeding and the 4-inch ones as supers. Please say if this is the correct style of the Stewarton hive. I remember seeing at a flower show, where prizes were offered for honey boxes, that one of the boxes was so constructed that the Judges took out the combs quite whole and returned them again. I took no interest in it at the time, but I should like now if I could get instructions how to make one like it. I am unable to understand the directions given for making "The Best Hive in Creation."—JAMES EDGAR.

[The difference between a Stewarton hive and a frame hive proper is that the former is eight-sided or octagon-shaped, consequently only four frames of one size can be got in the centre, and two of a different size for the outside, interchangeable with those on the opposite side, or as they are commonly made with four frames in the centre, the outside ones being bars only. The common Stewarton consists of three body boxes 6 inches deep, having nine bars, and whatever number of honey boxes the strength of the colony and district and season demand. These boxes are 4 inches deep, and have seven bars fastened (as indeed are all of the others) with brass screws, so that any comb can be removed. The Renfrewshire Stewarton has frames as described above, and the depth of the body boxes are 7 and 9 inches, while the supers are the same as the others. I have frequently seen eight employed on one hive at the same time, and all full. The Lanarkshire square hive, of various depths, with its divisible super, gives more central space over the combs than the octagon; but the latter is better adapted to the nature of the bees and is now in great repute both in this country and America, though it was at one time along with the octagon much abused and condemned. But, happily, bee-keepers discovered that they were under the thrall of trade journalism, being

forced as it were through it to adopt hives unsuitable for apiculture, hence the reaction now to the mother hive of scientific bee-keeping. I cannot see where the directions for making the best hive in creation can be made plainer. It is a simple yet cheap hive, the outside being covered with thin boards lapping each other, and bevelled under the edge to give drip, the divisions or hives proper sliding upon a ledge of iron, the hives to have a mouthpiece back and front, not necessary for bees to go out and in, but to prevent their being killed when any division is drawn out or pushed in. The front mouthpiece is closed by a piece of wood fixed between the posts, which the hive receives when pushed in. The divisions must fit neatly between the posts, and when the door of the case is opened behind should show as a case of drawers. If one cannot be made from the directions given it will be advisable to get one as a pattern from Messrs. Warnock & Walker, High Blantyre Station. By studying the directions and making a start the necessary work will suggest itself as you go along, and then we may help over any difficulty you cannot surmount, if it be specifically stated.—A LANARKSHIRE BEE-KEEPER]

* * All correspondence should be directed either to "THE EDITOR" or to "THE PUBLISHER." Letters addressed to Dr. Hogg or members of the staff often remain unopened unavoidably. We request that no one will write privately to any of our correspondents, as doing so subjects them to unjustifiable trouble and expense.

Correspondents should not mix up on the same sheet questions relating to Gardening and those on Bee subjects, and should never send more than two or three questions at once. All articles intended for insertion should be written on one side of the paper only. We cannot reply to questions through the post, and we do not undertake to return rejected communications.

Books (J. S. S.).—A good elementary work is Gill's "School of Art Geometry," price 1s., published by M. H. Gill & Son, 22, Warwick Lane, E.C. Messrs. W. & R. Chambers, 47, Paternoster Row, London, E.C., also publish elementary works on Plane and Solid Geometry, price 1s. 6d. each.

Chrysanthemums (W. A. W.).—Though the blooms sent are decidedly fuller than the others, they are not full enough for exhibiting and are very loose. They have been examined by an expert grower, and he is of opinion that the variety will only be suitable for decorative purposes, its pleasing colour recommending it for that purpose. The pink variety is not sufficiently distinct from Mrs. Sharpe, often called Incognita, and the bloom sent would pass for an inferior example of that variety.

Preserving Wood Trellis (Jas. Thomas).—The best thing to do with the woodwork would be to have it coated with creosote, the trellis being perfectly dry and the creosote applied hot, repeating until the wood ceases absorbing it. But why use wood? Wire trelliswork is not any dearer, and is when galvanised practically indestructible. Even wires along the wall are better than wood, being cheap and readily fixed by any labourer of ordinary intelligence. We have heard that petroleum is a good preserver of wood, and shall be glad to hear if any of our readers have tried it and with what results.

Vine Leaves Falling (Merchant).—The Vines, we should say, are in capital condition, as the wood is quite brown and the buds plump, without which the prospect of a crop next year is not good. It is not unusual for the leaves to fall by degrees—i.e., the upper part, leaving the lower part on the stalks, which will soon follow. Clear away the leaves as they fall, and keep the house as cool, dry, and as freely ventilated as the weather permits. When the leaves are all off, prune the Vines, the crop, we presume, being cleared, or if any Grapes remain they may be cut and bottled. It will suffice if the Vines are pruned between now and the new year, afterwards keeping them cool so as to insure complete rest.

Paneratiums (H. H.).—Paneratiums and Amaryllidaceous plants, most of them being natives of the West Indies and South America, require stove treatment, or a night temperature of 60° to 65°, but a few are hardy. We have no means of knowing to which section yours belong. If the former pot them in a compost of turfy loam with a little sand and charcoal added to keep the mass porous, and if the bulbs are in a dormant state do not keep the soil too wet. If the pots can be plunged in a warm bed of leaves, tan, or fibre, it will be an advantage, but this is not absolutely necessary. The hardy kinds are best started in pots, but in a cooler house. They produce beautiful flowers that are admired in bouquets.

Everlasting Flowers (J. A. F.).—The most easily raised of Everlastings are the Helichrysums, and the flowers are dried and employed in wreath-making and for other decorative purposes. The plants are raised and prepared for planting under the same treatment that is accorded Stocks and Asters. The flowers are much diversified in colour. For producing white flowers *Ammobium alatum* is very useful. Plants are readily raised from seed and grow freely in any fertile garden soil. *Antennaria margaritacea*, a hardy perennial plant 18 inches high, produces clusters of small white flowers, as does a still dwarfer plant *Gnaphalium arenarium*, the flowers of which are used for immortelle wreaths. There is no such work published on that to which you refer.

Digging amongst Raspberries (H. H.).—Much injury is done by digging roughly and deeply amongst Raspberries, which are essentially surface-rooting plants. Where the ground is of a heavy nature and has been made

quite firm through gathering the crops, it may be lightly pointed up with advantage, so as to admit the air without materially injuring the roots. In light soil it is not necessary to use any other implement than the hoe. We prefer to apply manure on the surface. If its appearance is objected to it may be turned lightly in with a fork, or have soil scattered over it, a few barrowfuls sufficing for a considerable space. The manure decaying on the surface, besides affording support to the canes, is valuable as a mulching in preventing the evaporation of moisture from the soil in dry weather.

Gleichenia Culture (R. G. O.).—They require to be grown in rough peat, torn in pieces with the hand and the finer particles rejected. Brown fibrous peat is the most suitable. Good drainage is necessary, and deep pans will answer quite as well as pots, they not being deep-rooting plants. The plants should be potted when they begin to grow, or early in March, and the old soil removed without injuring the roots. To the soil, before potting, add about a sixth of charcoal broken small, and a similar quantity of crystal sand. Work the soil in carefully amongst the roots, keeping the rhizomes well up, and potting moderately firm. Water thoroughly, so as to settle the soil about them, and do not water again until it is necessary, but before the plants are distressed by want of it, then giving a thorough supply. They are best in a light position, with just sufficient shade in very bright weather to prevent scorching, and should have a rather free amount of air, as they do not flourish in the close moist atmosphere of ordinary ferneries. A moderate amount of moisture only is necessary, and water should be sprinkled on the fronds. They require a temperature of 45° to 50° in winter, and 55° to 65° in spring by artificial means, and 10° to 15° rise from sun heat. The summer temperature will range 60° to 65° at night, and proportionately higher in the daytime. The chief things are an open free soil, free ventilation, and not too much water either at the roots or in the atmosphere.

Fruit Trees Cankering (An Old Gardener).—While it is not wise to be prejudiced against what you call "new notions," we think you are right in considering that the truth of the "insect theory" is not yet established beyond dispute. But this is not such a "new notion" as you appear to imagine. We have heard of it years ago, and seen the insects alluded to after the caker appeared, not before. Insects cause ulceration, as in the case of the *Aphis lanigera*, or American blight, but that is not canker as the term is generally understood. The following remarks cited from the "Cottage Gardener's Dictionary" are pertinent to your inquiry, and we have not a doubt there is a considerable amount of truth in them:—"This disease is accompanied by different symptoms, according to the species of the tree which it infects. In some of those whose true sap contains a considerable quantity of free acid, as in the genus *Pyrus*, it is rarely accompanied by any discharge. To this dry form of the disease it would be well to confine the term *canker*. In other trees, with sap abounding in astringent or gummy constituents, it is usually attended by a discharge. In such instances it might strictly be designated *ulcer*. This disease has a considerable resemblance to the tendency to ossification, which appears in most aged animals, arising from their marked tendency to secrete the calcareous saline compounds that chiefly constitute their skeletons. The consequence is an enlargement of the joints and ossification of the circulatory vessels and other parts—phenomena very analogous to those attending the cankering of trees. As in animals, this tendency is general throughout their system; but, as is observed by Mr. Knight, 'like the mortification in the limbs of elderly people,' it may be determined, as to its point of attack, by the irritability of that part of the system. This disease commences with an enlargement of the vessels of the bark of a branch or of the stem. This swelling invariably attends the disease when it attacks the Apple tree. In the Pear the enlargement is less, yet is always present. In the Elm and the Oak sometimes no swelling occurs; and in the Peach we do not recollect to have seen any. The swelling is soon communicated to the wood, which, if laid open to view on its first appearance by the removal of the bark, exhibits no marks of disease beyond the mere unnatural enlargement. In the course of a few years, less in number in proportion to the advanced age of the tree and the unfavourable circumstances under which it is vegetating, the swelling is greatly increased in size, and the alburnum has become extensively dead; the bark above it cracks, rises in discoloured scales, and decays even more rapidly than the wood beneath. If the canker is upon a moderately sized branch the decay soon completely encircles it, extending through the whole alburnum and bark. The circulation of the sap being thus entirely prevented, all the parts above the disease perish. Trees injudiciously pruned, or growing upon an ungenial soil, are more frequently attacked than those which are advancing under contrary circumstances. The soil has a very considerable influence in inducing the disease. If the subsoil be an iron gravel, or if it is not well drained, the canker is almost certain to make its appearance amongst the trees they sustain, however young and vigorous they were when first planted. All these facts before us unite in assuring us that the canker arises from the tree's weakness, from a deficiency in its vital energy, and consequent inability to imbibe and elaborate the nourishment necessary to sustain its frame in vigour, and much less to supply the healthy development of new parts. It is quite true that over-luxuriant trees are particularly liable to this disease; but over-luxuriance is really a demonstration that the tree does not digest and secrete its juices healthily." We do not consider that canker arises from either weakness or exuberance only, but both are contributory causes, and when they exist remedial measures should be adopted accordingly.

Names of Fruits.—The names and addresses of senders of fruit to be named must in all cases be enclosed with the specimens, whether letters referring to the fruit are sent by post or not. The names are not necessarily required for publication, initials sufficing for that. (R. S.).—1, Eyewood; 2, Chaumontel. (T. Buckersfield).—The Pear was so loose in the box and so much battered it was impossible to distinguish it. (Charles Denning).—1, Brougham; 2, Belmont. (G. Picker).—1, Colmar d'Aremberg; 4, Doyenné Boussoch; 5, Colmar; 6, Winter Nelis; 7, Easter Beurré; 8, Beurré d'Aremberg. (J. Cornhill).—The Apple sent as a seedling is marvellously like Fearn's Pippin. The other is Golden Spire.

Names of Plants.—We only undertake to name species of plants, not varieties that have originated from seed and termed florists' flowers. Flowering specimens are necessary of flowering plants, and Fern fronds should bear spores. Specimens should arrive in a fresh state in firm

boxes. Slightly damp moss or soft green leaves form the best packing, dry cotton wool the worst. Not more than six specimens can be named at once. (Slough).—*Sternbergia lutea*.

Reversible Frames (J. H.).—Your letter with a reply by "A Lanarkshire Bee-keeper" arrived too late for insertion in the present issue.

Closing Hive Entrances (R. M.).—They must not be closed entirely, but if large the apertures should be reduced. Many persons restrict them so that mice cannot enter, and yet admit air for the benefit of the bees.

COVENT GARDEN MARKET.—DECEMBER 9TH.

LITTLE alteration from last week. Supplies still heavy, especially Grapes, moving freely at low prices.

AGRICULTURAL PROGRESS.

To those who have given much thought to agricultural depression and its causes comes not unfrequently a feeling of sadness and distrust—sadness arising from a keen sense of past and present difficulties, distrust of the future and the probable additions to our burdens which it may bring to us. Bold indeed would the man be who ventured to predict the advent of more prosperous times in the immediate future, for farming is undoubtedly in a state of transition. A radical change is surely if slowly being effected in the culture and cropping of the soil, in the rearing and management of live stock, and in the marketing of farm produce. Cause and effect are being looked into more closely, science is brought to bear upon practice as it never was before; to energy of action is combined clearness of aim, as the causes of failure or success open up to us. But there is still much ignorance, and its invariable concomitant of prejudice, to overcome; the downright assertions of ignorance, the rash action arising from superficial knowledge, still clog our progress and hinder our efforts for the general good. The clinging to the use of farmyard manure undoubtedly has some justification in the fact that it contains all the elements of plant fertility, notwithstanding the equally weighty fact that the manufacture and application of such manure is exceedingly costly. It is a safe agent in imparting fertility to the soil, and the rough-and-ready practitioner will doubtless cling to it as long as he can. But we already know that plant food is absorbed in a gaseous state, and this fact is literally a golden key to the door of the treasury of Nature, and we are gradually learning how to use it. Nobody has yet won the prize of £10,000 which was offered a few years ago by the French Government for a method of using the nitrogen of the atmosphere for purposes of fertilisation, yet the ploughing-in of green crops for manure is doubtless the nearest approach to such a discovery,

it being certain that such crops receive fertility from the atmosphere and impart it to the soil as they decay. This is certainly a step onwards, the full importance and significance of which one cannot yet realise. Cordially do we invite especial attention to it now with a view to the inducement of thoughtful discussion before the time comes round again when it may be turned to account. Let us try and grasp the practical value of this sowing and ploughing-in of green crops to the farmer. Take a familiar example by way of illustration once more; the lesson is an easy one, yet it must be thoroughly mastered if we are to derive full benefit from it. A Wheat stubble of some twenty acres is very foul with couch grass. Had the autumn been as fine as it was last year this foul grass would have been taken out of the soil and burnt. It was not fine, and we could only have the grass forked out where it was thickest. As early as possible next spring the soil will be cleaned by ploughing, stirring repeatedly by the cultivator and harrows, and if necessary the clods will be crushed with a Cambridge roller to loosen the grass for the harrows. Then, instead of leaving it for a summer fallow, White Mustard will be sown at the rate of 20 lbs. of seed to an acre, and when this crop is fully grown it will be ploughed in. Hitherto we have recommended ploughing in the green crop when it is in full flower, but a little more attention to the composition of plants shows that the seed contains a much larger proportion of potash and phosphoric acid than any other part of a plant, and it is well, therefore, to wait till the seed is quite half ripe before ploughing in the crop. A trifle this? Well, perhaps so in a plant or two, but trifles mount up in the aggregate, and in this instance they "mean money" just as they do in many another. So fully convinced are we of the high value of this process that we shall continue both to practise and preach it.

Another branch of farming in which progress has been made is the laying down land to permanent pasture. We have ample proof before us now that nine-tenths of an old pasturage consists of inferior native Grasses, which certainly give a clothing of herbage, but which is altogether inferior to pasture of the best Grasses. If anybody doubts this the proof is easy, for we have only to render a piece of land clean, to see that it is well drained either naturally or artificially, to reduce the surface to a fine tilth, to impart enough fertility to it to insure a free strong growth, and to sow it with a mixture of such Grasses as have so often been enumerated in these pages—Cocksfoot, Timothy, the Fescues, Dogstail, Meadow Foxtail, with a due proportion of Yarrow, Red Clover, Cow Grass, Alsike, and Dutch Clover. No contrast can well be stronger than between the growth from such a mixture and that from old pastures of an ordinary type. By careful preparation of the land, by equal care in the treatment of the young pastures, particularly in the first two or three years after the sowing, we are able to keep, and keep well, from twice to three times as many sheep per acre as can usually be done upon old meadows. So clearly has this been proved to demonstration that there can no longer be any doubt it was from sheer ignorance that the outcry was raised against laying down land to permanent pasture. We know now that, done in the right way, the process is neither slow nor uncertain.

WORK ON THE HOME FARM.

Ploughing is being done upon our large arable farms upon every favourable occasion, but there has been considerable hindrance to this work from wet weather. It is in such broken weather that we realise the value of what is often termed a mill house, which is a building covering horse gear for driving machinery. Chaffing, corn-crushing, pulping, and all the usual machine work of the farm may so be done, men and horses being kept off the land and under shelter without actual loss of time. A zealous bailiff will sometimes turn out the horses to work on wet days, but while not minding work in the open during a few showers, we decidedly object to an amount of exposure of servants and horses to inclement weather, which may be considered inhuman. We much fear that illness, which is sometimes fatal, arises from exposure for hours in the rain of men whose clothing is ill calculated to keep them either dry or warm. The ploughing done recently has been what may be termed ridge plough-

ing, by which the land is thrown up into ridges and fully exposed to the action of the weather. We do this willingly at the risk of some slight loss of nitrogen, but then soil so exposed is acted upon so readily by wind and sun in spring that we can always have it ready for sowing, and in better tilth than land ploughed in the ordinary way. Foul land, too, will be ridge-ploughed to enable us to scarify and clean it early next year. The heavier the land the more important is it that it should be opened up to the action of the air, and it is obvious how mellow and open soil must become after two or three months of such exposure.

It is a useful plan to watch the action of drains now, so as to ascertain if they are uninjured and bring off the water freely. Soil that is water-logged may now be discovered simply by walking over it a few hours after heavy rain. Drainage is one of the matters about which there must be no false economy. We must set the land free from accumulations of water, for wet land cannot be fertile; the fertility is really locked up, and no matter how freely we try to impart more and more fertility to the soil, we never can get free growth or a full crop till the drainage is sound. No doubt this is a matter requiring sound judgment and some caution, yet with the exercise of due care it is not difficult to ascertain whether or not it is necessary to make drains.

ROOTS AND SEEDS AT ISLINGTON.

THE stands of seeds and roots at the Islington Show contributed by the leading firms of seedsmen make an imposing display in the gallery, and are as usual very tastefully arranged. Messrs. Sutton and Sons, Reading, have an extensive collection of finely developed roots—Mangolds, Swedes, and Turnips of their own selected varieties figuring prominently at the upper part of the stand. Numerous clean and excellent samples of seeds are included, and with the specimens of the various mixtures of grass seeds for pastures and lawns occupy the lower and foremost portion of the stand. The principal varieties of roots represented are Mangolds, Mammoth Long Red, Berks Prize Yellow Globe, Ox-heart Yellow Globe, Yellow Intermediate, and Golden Tankard. The Champion Swede and Purple Top Yellow Hybrid Turnip are the chief varieties of the other roots shown.

Messrs. Webb & Son, Stourbridge, contribute a handsome stand of similar excellence to that which was so much admired at Birmingham recently, and to which we referred last week. Potatoes, Mangolds, Swedes, Turnips, Wheats, Barleys, and other grains, together with general samples of flower and vegetable seeds. Specimens of their special manures form the major portion of the exhibits, all being of admirable quality.

Messrs. J. Carter & Co., High Holborn, have an exceedingly attractive and interesting exhibit, which, like those already mentioned, comprises a great number of fine roots, mostly of the firm's specially selected varieties, which have gained much favour with many agriculturists. The specimens of the Hybrid Wheat which we noticed some time since were also shown, and formed a feature of much interest to a number of visitors.

Messrs. Harrison & Son, Leicester, had a smaller but choice exhibit of fine roots and clean good seeds.

CHICKWEED.—A friend of mine, a large and excellent farmer in this neighbourhood, who keeps his land scrupulously clean, has this autumn been very much troubled with chickweed, which has been most prevalent in one or two of his most highly cultivated fields. He would be glad to know how it could have generated. Can you throw any light on it? If so, the information will greatly oblige.—WILLIAM W. BROWN.

[The chickweed has generated from seed, but whether this has been introduced with other seeds that have been sown, or whether it has lain dormant in the soil for some time, and brought near the surface by deeper ploughing than usual, we have no means of knowing. Charlock and other seeds buried beyond the influence of air retain their vitality for years, and germinate freely when turned up by working the land a few inches deeper than before.]

REMARKS.

29th.—Heavy rain till 10 A.M.; warm, damp, and drizzly all day.
30th.—Warm and damp, with heavy rain all the afternoon.
1st.—Colder, fine and bright.
2nd.—A little fog in morning, but generally fine.
3rd.—Cloudy early; showery morning; wet afternoon and evening; gale at night.
4th.—Wet, with westerly gale; fine after mid-day, with sunshine till sunset; rain soon after; evening fine.
5th.—Generally fine till 5 P.M., steady rain afterwards.
Another wet week; the temperature nearly the same as in the previous week, and rather above the average.—G. J. SIMONS.

FOURTH SUNDAY IN ADVENT.

PLANTS CERTIFICATED IN 1885.

THE Committees and Judges of the leading Horticultural Societies entrusted with the important task of determining the value of the numerous novelties submitted to them have this year been busy, for the number exhibited has been large, and it has required vigilant care in the selection to avoid bestowing honours upon plants of uncertain merit, and at the same time not to pass those of real worth. The greatest portion of this work has necessarily fallen upon the Floral Committee of the Royal Horticultural Society, and it is very satisfactory to observe that, owing to the excellent judgment exercised in granting or withholding their awards, the certificates are becoming more valuable as official recognition of plant merit. The Judges engaged by the Royal Botanic Society invariably have some scores of novelties brought before them at the four exhibitions held annually in Regent's Park, and though, perhaps, certificates are rather more freely granted there than at Kensington, there is no material cause for dissatisfaction. It must be considered, too, that the dual system of botanical and floricultural certificates adopted at Regent's Park allows a greater latitude than the ordinary first-class certificates of the other Society. The award of botanical certificates is also undertaken by the Scientific Committee at Kensington, but these are now as rare as the doubtful second-class honours have fortunately become, and which at one time were much too frequently bestowed. What is really needed is a reliable indication to the horticultural world of what plants amongst the hosts of new claimants to popular favour are worthy of culture, either as improvements on older forms of a similar type, or as new introductions. Merely certificating a plant because it is new, or because it is distinct, is not sufficient; if it does not possess some qualities to recommend it as a garden plant, no award should be granted by Horticultural Committees.

Next to the two Societies already named the Floral Committee of the National Chrysanthemum Society has awarded the greatest number of certificates, though nearly all these have been confined to the special object of the Society's existence—the Chrysanthemum. This Floral Committee is a comparatively youthful institution, and perhaps in a few instances their zeal has somewhat outrun their discretion, certificates having been very freely granted. More experience at their work, and a fuller appreciation of its importance, will probably render them more careful in their awards. They have unquestionably done much valuable service, and it is with a desire to see the Society take the position it deserves that we advise a more rigid economy in their honorary awards.

The National Carnation and Picotee Society, the Judges at the Crystal Palace and a few other leading shows, have also assisted in the work of selection, but it would be well if local societies refrained from granting certificates, unless it be conditionally recommending the exhibitors to submit their productions to the higher tribunals. There is one form of certificate—namely, for culture, which many local societies

might advantageously grant, and such would be of far more practical value to gardeners than the usual recognition accorded.

Taking the awards of the bodies named, we find that the substantial total of 346 plants and flowers have been deemed worthy of certificates, several having been honoured by two or more societies. Of this total 127 are miscellaneous, stove, greenhouse, and hardy plants, species, hybrids, or introduced varieties, and the remaining 219 are florists' flowers, or varieties of garden origin. These numbers are favourable signs of the activity prevailing in the horticultural trade, and also indicate how great must be the demand for novelties when so much labour and expense are incurred to provide the public with additions to the already long lists of cultivated plants. At no period in the history of horticulture have such enormous numbers of novelties been introduced from other countries or raised in our own as at the present time, and if any proof were needed that the love of horticulture is extending, this fact affords it most convincingly.

A brief glance at the principal groups of plants will indicate to some extent the direction of popular favour, and as for several years past we must again place the Orchids at the head of the poll with a large majority. No less than seventy-six of these have been certificated this year, and adding to these 100 other novelties in the same family that have been described or figured in the principal gardening and botanical publications of Europe during the same time, we can gain an idea of the rapidity with which collections are being increased. The *Odontoglossums* preponderate amongst the certificated Orchids, twenty-one having been chosen for honours, a good proportion being varieties of the *O. crispum* type. Next in number are the *Dendrobiums*, ten being selected, all either hybrids or varieties of such well-known species as *crassinode*, *Falconeri*, *heterocarpum*, *macrophyllum*, and *nobile*. Of *Cattleyas* nine have been certificated, including some grand varieties of the leading types. Seven *Lælias* have found favour with the censors, and the remainder is made up of *Calanthes*, of which several beautiful hybrids have been obtained, *Cypripediums* and miscellaneous species. It is worthy of remark that *Angræcum* or *Aeranthus Leonis* was shown on the same day by five exhibitors, and each obtained a certificate—a very uncommon occurrence.

Following the Orchids, in point of numbers, strangely enough, come the *Chrysanthemums*, with a total of thirty-eight, the largest number of varieties that have ever been certificated in one year. Again we find one group largely predominant, the Japanese having been increased by twenty-seven varieties, and some of these may be expected to take a prominent place amongst the exhibition varieties. It is quite evident that the Japanese forms with the early-flowering and what are termed decorative *Chrysanthemums* are advancing most rapidly in favour, and for purposes of utility the incurved forms, though so highly esteemed by florists, will have an inferior position. A well-grown incurved bloom is very handsome as regards symmetry, but it is of little value in ordinary floral decoration, whereas the more graceful Japanese, the *Anemones*, the reflexed, and the single varieties can be employed to excellent advantage in numberless ways.

Fuchsias follow the *Chrysanthemums*, twenty-one having been found worthy of special notice by the Floral Committee at Chiswick. A large collection has been grown there during the year, and from these the number mentioned has been carefully examined and considered distinct and meritorious enough to deserve certificates. This list is a substantial addition to the varieties already in cultivation, but it should be remarked that several of these were not strictly new, though not generally known. They were all good varieties, and the fact of so many being recognised may serve to draw some additional attention to the usefulness of *Fuchsias* as flowering plants for the conservatory. Specimen *Fuchsias* are occasionally seen at exhibitions, but except in the west of England it is seldom that they are shown in their best

condition, though well-grown examples are valuable additions to any exhibition.

Nearly equal in numbers are the Tuberous Begonias (nineteen), both single and double forms from several raisers having been found sufficiently distinct, notwithstanding the great advance that has been made in recent years. The general improvement has, however, been so marked that probably certificated varieties will decrease in number each year, especially since it has been proved that strains of seed in each of the principal colours can be obtained true. Of *Gladiolus* eighteen have been honoured, chiefly of the *gandavensis* type, but a few forms of *G. Lemoinei* have been added, and these will soon constitute an interesting group of free-flowering hardy varieties that will be duly appreciated in many gardens. A dozen each of Dahlias and Amaryllises have gained favourable notice, while Cinerarias, Carnations, and greenhouse Rhododendrons are equal with ten certificated varieties each. The last-named include some extremely beautiful forms, and it is surprising how much they are being improved in the hands of skilful hybridisers and cultivators—the colours are being more diversified, the flowers enlarged, and, what is of still more importance, the habit is being rendered dwarfer and more compact. This point cannot receive too much attention, for the chief failing of these Rhododendrons has hitherto been the tendency to become straggling.

Pelargoniums and Roses have been well represented amongst the novelties, and nine each were certificated, but to the former must be added four of the much-admired Ivy-leaved varieties, all double forms, the flowers of which are found so useful for cutting and arranging either in bouquets or vases. One of the zonal varieties, *Volonté Nationale Album*, deserves special notice, since it has obtained no less than four certificates this year from different societies. It is encouraging to note that six of the Roses are of English origin, one of which, Mrs. John Laing, has obtained many honours.

Many other useful and beautiful plants have received official recommendation to public notice, but they need not be referred to specially here. It is, however, remarkable what a preponderance of flowering plants figure amongst the novelties, those distinguished as “fine-foliage plants,” being comparatively few; even including Ferns, Sarracenias, and Nepenthes, they only number twenty-two, indicating a great change in popular taste.

KEEPING GRAPES.

It is not difficult to maintain a supply of ripe Grapes the whole year round if the accommodation for growing them is equal to the demand. Not unfrequently are the fruits of such late varieties as Alicantes and Lady Downe's kept in good condition for eight months after they are ripe, and placed on the table with Black Hamburgs and other early-forced Grapes towards the end of May. It is surprising how fresh and plump they will keep until that time, or even into the following month if desired.

The length of time that late Grapes will keep fresh, however, depends upon the time they are thoroughly ripe and the treatment they receive during the last stages of development. If ripened by the end of September under moderately cool airy conditions, they will generally keep well, provided the atmosphere of the house in which they are to hang is properly regulated. It is a great mistake to ripen Grapes in October by the aid of strong fire heat, for this is not only detrimental to their keeping satisfactorily, but it tells materially on the crop the following season, and perhaps proves disastrous to the Vines if persisted in for a few years.

When the Grapes are ripe by the time named, and under the conditions most suitable, they give comparatively little trouble as far as keeping them is concerned, until the damp foggy days of November set in. Even light irregularities in the temperature and the atmospheric conditions of the house do not prove so injurious to them as would be the case towards the close of the month or the early part of the next. It is wise to maintain a regular temperature as nearly as possible, being guided by external conditions, and ventilate the house judiciously during that trying month. No doubt the most critical period for Grapes is

from the time the foliage commences to fade until it has fallen from the Vines. During this stage the berries are most likely to be affected by mould, as they will be quickly if any injudicious course is followed in the regulation of the atmosphere.

The idea so generally prevalent, that every plant must be removed from the houses during the period named, is a mistake, for bedding and other plants can be kept in them without the slightest injury to the Grapes or Vines. If such plants can be accommodated elsewhere so much the better, but large numbers who may be required to keep a house of late Grapes are not so favourably situated. We are generally compelled, by the want of space elsewhere, to keep a large stock of *Selaginellas*, small Ferns, and other plants for decoration in these structures, and they are worse than Pelargoniums, as these require but little water now. A little more care is, however, needed in ventilating the house.

In damp localities, where the atmosphere is saturated with moisture, and dull foggy days are the rule, it is very difficult to keep the Grapes in the house with Ferns that require to be constantly watered. Once or twice during the past few years we have been compelled to remove such plants from the house, but this has only been necessary when long spells of bad weather have been experienced. The difficulty that arises under such circumstances is to remove the moisture that condenses on the surface of the berries, which may be effected by keeping the temperature of the house a few degrees warmer than is usually necessary. The dull appearance of the berries at once shows this condensed moisture, and if immediately removed the Grapes can be preserved.

The temperature of the house in which the Grapes are hanging should be kept from 55° to 60° at night, and from 60° to 65° during the day, the heat being regulated by the external atmosphere, whether mild or cold. If the house is full of plants it may be necessary on some occasions, even during cold weather, to maintain the temperature at the highest figures given, as well as when damp and foggy. If the house is empty and the border has been mulched or covered to prevent evaporation from the surface, even a lower temperature of 5° or more by day, as well as by night, may safely be practised. Fire heat in such cases only is needed to keep the atmosphere sufficiently dry to prevent moisture from being condensed on the berries. During sharp frosty weather, even when no plants are in the house, the temperature should be kept moderately high.

Although the regulation of the heat, according to circumstances, is very important in the preservation of Grapes, it is no more essential than the ventilation of the structure. The idea which formerly existed, and is not even now obsolete, of admitting a little air and heat daily, irrespective of external conditions, cannot be too strongly condemned, for if persisted in the Grapes are certain to decay. When the air outside is moist the ventilators should be kept closed, and a steady heat maintained in the house, regulated by the amount of moisture inside. When the outside atmosphere is dry every advantage should be taken to ventilate the house liberally.

Care is also necessary in applying water to the roots of the Vines. If none is given from the time the Grapes are ripe until they are cut from the Vines the roots may suffer, and the Grapes commence shrivelling. If the border needs water it can be applied at any time until the end of October, but afterwards a favourable opportunity should be selected when the atmosphere outside is dry, so that the moisture inside can be expelled by free ventilation and the use of fire heat. Watering the border, however, should if possible be avoided during that critical period when the foliage is decaying. After the leaves have fallen water may be given if it is needed. The roots of late Vines are inside and out, and we have often experienced very wet weather during the time the foliage is dying, but no difficulty has been experienced in keeping the fruit. Far more harm is likely to result from a superabundance of moisture in the atmosphere, which is condensed on the berries, than by heavy rains or watering the Vines at their roots.

Many allow the Grapes to hang upon the Vines as long as possible after the foliage has fallen, but this is a mistake; the Grapes will keep in a dry airy room just as well as they will upon the rods. Allowing the fruit to remain upon the Vines until February, or when the sap rises, only imposes an unnecessary additional burden upon them; they are liable to bleed when pruned, and if this does no harm it certainly does no good, it also robs them of that season of complete rest which is so essential to success. The sooner the fruit is cut after the new year the better, and in every case where practicable we strongly advise this to be done, then the Vines can be pruned, kept cool afterwards, and thus have a good period of rest.

After Grapes are cut from the Vines they will keep perfectly well in any dry airy room if the wood from which the bunches

hang is placed in bottles of water. It does not matter which end of the wood is placed in water, for either will do equally well. I have never found any difference, and it is often difficult to place in the bottles what may be termed the right end, or that nearest the stem of the Vines. This, with such varieties as Alicantes, is often too short, and therefore the end beyond the bunch must be used. The bottle should be filled with clean water, and so that the stem leaving the bunch will reach the water at whatever angle the bottles may be suspended. It is immaterial whether charcoal is placed in the bottles of water or not; we never adopt this plan now, and find no difference. The idea that too much water will pass to the berries unless the stem has been charred, or the tubes through which water passes stopped by other means, is a mistake. We always place the stem into the water as cut from the Vine, and find the Grapes keep well. Some use clay to stop the mouth of the bottles to prevent evaporation, but this is only a waste of time, and does no good if only an attempt is made to regulate the temperature and conditions of the room to prevent a moist atmosphere and the condensation of moisture upon the berries. The less heat that can be used to accomplish this the better. It is also necessary to examine the bottles occasionally to see that the stem is still in the water; if this is not the case they must be filled, or the Grapes will shrivel instead of remaining fresh and plump. Care must also be exercised in looking over the bunches lest any berries should decay, for unless these are removed at once they will soon destroy the whole bunch by decaying all those that surround it.

The fruit room must be freely ventilated whenever the weather is favourable and will allow of this being done, the same conditions being observed as when the Grapes are hanging upon the Vines. It is surprising how well the fruit can be kept even in what may be regarded as unsuitable places, provided due care is taken in regulating the atmosphere in the room. It is, indeed, very difficult to lay down any hard and fast rule for their management after they are cut, because the position of the room, as well as other varying circumstances, all tend to prove that intelligent observation must guide those in charge, as rules probably would in many instances prove unsuitable.—WM. BARDNEY.

NEW ROSES.

THERE was a time when Rose-growers waited in a flutter of expectation for the new catalogues which came pouring in from France, and they were eagerly scanned as to the hope of new acquisitions which should surpass in excellence and beauty anything that we already possessed. Sometimes these expectations were realised, when, as in 1853, three such Roses as Gloire de Dijon, Jules Margottin, and Général Jacqueminot gladdened the Rose-growers. 1861 was another grand year, for it gave Charles Lefebvre, Duc de Rohan, Maréchal Vaillant, Maurice Bernardin, Mrs. Charles Wood, and Prince Camille de Rohan. But we get no such years now: perhaps it is unreasonable to expect it. We have so many beautiful Roses that it seems well nigh impossible to get anything to excel them, and hence we take the new-Rose fever in a much milder form than we used to do. We have learned to discount the magnificent descriptions, when all the glowing adjectives of the French language were used to describe the novelties which the raisers had to offer, and we have, rather than take these descriptions *au sérieux*, looked upon them as good jokes, and have measured our expectations rather by the doings of the raisers in former years. When a raiser has mostly given us good Roses we place confidence in his new bantlings; when, on the other hand, he has generally given us indifferent flowers we do not care to trust him for the future. In looking through the list which I have now before me of the new Roses, I find fifteen Teas and thirty-four Hybrid Perpetuals, besides a few miscellaneous Roses. I shall take them under the names of their raisers, as being likely to give a better indication of their value, taking Teas first.

TEAS.—GUILLLOT ET FILS.

Comtesse de Frigneuse.—A robust free-flowering variety. Flowers full, of a beautiful clear canary yellow; the blooms large. As Guillot has only this one Tea, and as he has already given us some good Roses, we are hopeful that this may be an acquisition.

NABONNAND.

It is well known that this raiser every year floods the market with new varieties, very few of which remain permanently in our catalogues; for in the National Rose Society's catalogue of exhibition Roses I find only one of his, Francisca Krüger. In the present year he offers five.

Camille Roux.—A large globular flower. Plant very vigorous and free-flowering; colour, centre lively red, borders of petals rose.

Ecardelphé.—If the superlatives used for the description of this Rose indicate anything it must be something grand. Everything is "très!" It is very vigorous, very floriferous, very large, very full, very well formed, and very sweet, while the colour is a perfect yellow. What more, my masters, can you want? If there is truth in words everyone ought to go in for this, but —

Flavien Budillon.—Here again the superlatives come in, but not quite so many as in the previous description, still they are abundant—very vigorous, very free-flowering—flowers very large, full, globular, cup-shaped, beautiful tender rose colour.

Reine Olga.—Robust, very vigorous; large full flowers, perfect shape, colour coppery red; very sweet-scented.

Suzanne Blanchet.—Very vigorous and free-flowering, of imbricated form; colour beautiful flesh rose.

LEVET.

Claudius Levet.—Vigorous and free-flowering, large and full, of a beautiful carmine rose shaded with purple, centre salmon colour.

Edmond de Bianzat.—Plant vigorous. Flowers large, full, of good form; colour a beautiful salmony peach.

Marguerite Ramet.—Beautiful flowers, well formed, large size; colour beautiful china rose, the centre veined with carmine rose, edge of petals bordered with bright rose.

LEVEQUE.

Comtesse Horace de Choiseul.—Vigorous. Flowers large, well shaped; colour delicate rose shaded with copper yellow.

PERNET, PÈRE.

Madame David.—Vigorous. Flowers large, nearly full; colour tender rose edged with white, shaded salmon rose.

Souvenir de L'Admiral Courbet.—Moderately vigorous, having some likeness to Polyantha Roses. Flowers medium size, full or nearly so, of a lively red colour. Very free-flowering variety for borders.

DUBREUIL.

Marquise de Vivens.—Very free-flowering. Flowers medium or large, of a most charming colour, the base of the petals white; the edges lively carmine, showing at the front china rose colour, gradually shading into straw colour towards the centre; inside flesh colour shaded with sulphur yellow. The buds are very long, of fine form. This Rose has a delicacy of colour and refinement impossible to describe. Well, at any rate the raiser has made a good attempt at doing so, and excites in no small a degree one's curiosity as to what it may turn out in reality.

SOUPERT ET NOTTING.

Reine Nathalie de Serbie.—Very vigorous. Flowers large, well formed, flesh rose in colour on cream-coloured ground lightly shaded with yellow.

GONOD.

Souvenir de Hélène Lambert.—Very vigorous, thorny, very floriferous; colour yellow, reverse of petals deep rose.

BONNAIRE.

Souvenir de Victor Hugo.—Vigorous. Flower large and full, bright pink, slightly edged with yellowish white; centre yellowish.

HYBRID PERPETUALS.—EUGÈNE VERDIER, FILS AÎNÉ.

Amiral de Joinville.—Flower large and well formed; colour deep red shaded with purple; very sweet-scented.

Denis Cochin.—Very vigorous. Colour crimson red shaded with velvety crimson.

Chatelaine d'Eu.—Larger well-formed flowers, carmine red lighted with brilliant purple; centre pansy-coloured violet.

Léon Delaville.—Vigorous. Large well-formed flowers, red deep shaded, flushed with carmine, lighted up with violet crimson.

Louis Callu.—Large flower. The description of colour baffles one—purplish red, shaded with puce, marbled with white.

Prince Waldemar.—Vigorous. Colour cerise red shaded with silvery white.

Princesse Marie d'Orléans.—Vigorous. Colour lively cherry red shaded with silvery white.

Madame Vauvel.—Very vigorous. Flower extra large, very large petals, lively rose colour.

SCHWARTZ.

Auguste André.—Vigorous. Colour silvery rose, lilac centre, passing to pale rose.

Climbing Monsieur Boncenne.—A rampant-growing variety of this well-known variety, very free-flowering.

Climbing Pride of Waltham.—This has also originated with Paul & Son at Cheshunt, and is being sent out by both firms. Of strong growth. Flowers like the type.

Souvenir d'Eugène Karr.—Flowers medium size; colour reddish scarlet passing into puce; back of petal with whitish shading.

MARGOTTIN, PÈRE.

Raoul Guillard.—Flowers large, full, very sweet-scented, brilliant vermilion red; back of petals amaranth colour. My good old friend rarely sends out a new Rose, so that one is hopeful when he does so it is something good,

LACHARME.

Clara Cochet.—Vigorous, erect growth, full, with large petals; clear rose colour, centre brighter.

I may say the same of honest old Lacharme, to whom we are indebted for so many good flowers, and who has sent out so few bad ones. As this appears to be his only Rose this year let us hope it may confirm his previous reputation.

LEVÊQUE.

Comtesse Freisinet de Bellanger.—Very vigorous. Flowers large, full, of a beautiful clear rose colour shaded with bright rose.

Madame Baulot.—Flowers large, full, imbricated; colour bright rose shaded with earmine.

Maréchal Canrobert.—Vigorous. Flowers large and full; colour cerise red shaded with earmine and purple.

Princesse Amédée de Bréglié.—Very vigorous. Flowers large, full, and globular; colour clear bright rose, cherry colour in the centre, back of petals silvery.

Professeur Maxime Cornu.—Vigorous. Flowers large, full; colour lively red without any shading. Very free-flowering.

MOREAU.

Docteur Pinel.—Very vigorous. Flowers very large, full, of good form, flowering in clusters; colour vermilion red shaded with earmine.

Madame Lefebvre.—Vigorous. Flowers large, flowering in clusters; colour satiny rose, deeper in the centre.

Nicholas Leblanc.—Flowers very large, globular; colour cherry red passing into delicate rose.

LIABAUD.

Madame Gomot.—Very vigorous. A seedling from Souvenir de la Reine d'Angleterre; very large flowers, nearly full; colour lively, glossy rose.

Madame Musset.—Very vigorous. Flowers very large, full, of good shape; colour clear red.

Madame Rebatel.—Very vigorous; a seedling from La Reine. Flowers very large, well shaped; colour bright rose shaded with lighter tint of same colour.

Madame Villy.—Vigorous, having the appearance of Rose Madame de Cambacères. Flowers large, full; colour brilliant amaranth red.

SOUPERT ET NOTTING.

Madame Ph. Dewolfs.—Very vigorous. Flowers large, full, shape of Centifolia; colour madder rose shaded with clear violet.

Madame Pierre de Beys.—Vigorous. Flowers large and full; vermilion red passing into shaded earmine.

VIGNERON.

Madame Sanglier.—Vigorous. Flowers large, full, globular; colour amaranth red, reverse silvery white.

Monsieur Moreau.—Vigorous. Flowers large, full, globular; colour lively rose, passing into delicate rose; reverse of petals silvery.

GONOD.

Rosieriste Chauvry.—Vigorous. Flowers large, full, a seedling from Victor Verdier; colour fiery red, the deepest colour of this series.

J. LUDOVIC.

This is quite a new name to me, nor do I know his *locale*. It sounds more German than French, and his Rose is named after that enthusiastic rosarian

Frederick Schneider II.—Vigorous. Flowers large; colour lively rose shaded with brilliant red.

PERNET PÈRE.

Souvenir de Victor Hugo.—Vigorous. Flowers large, nearly full, globular, beautiful satiny rose.

It will thus be seen that Mons. Eugène Verdier heads as usual the list as far as number goes with eight varieties, while such cautious growers as Lacharme and Margottin have only one each. It is utterly impossible to say where we are to look for the prizes; but however glowing the descriptions they do not strike one as promising anything very novel or extraordinary.—D., Deal.

ICE HEAPS.

The remarks and illustration anent this subject (p. 512), together with the fact that we are now actually engaged in the work to which they refer, induce me to bring under the notice of your readers a

method of preserving ice that is not so well known as it deserves to be. I refer to "stacking ice" in the open, and the *modus operandi* of which I have not seen practised elsewhere. There are no doubt many of your readers who would like to have their own store of ice had they but the accommodation in the way of a house in which to preserve it, and yet in most cases they possess all that is necessary to gratify their wishes in this respect without expending a penny in excavating and fitting up an ice house. This is to be done by following in detail the instructions herein given, which represent the method of procedure practised here for several years with the most satisfactory results.

In a valley shaded by spreading trees, the foliage of which shades the ice rick from the direct rays of the sun during the summer and early autumn months, and at the bottom of a slope having an angle of about 30°, thus affording ample drainage—we commence our rick, and build "uphill" about 12 or 15 feet to the edge of the cartway, which we made for the occasion. We then place some hurdles at the bottom and ends to prevent the ice when "tipped up" at the top from going beyond its bounds. It is then well broken with mallets, and boiling water applied as the work proceeds to consolidate. The section of the rick when finished somewhat represents that of a three-quarter span house, the cartway representing the wall plate of the hip-roof. Then a man, with a ladder placed against it, spade in hand, commences at the top and trims the whole rick right round to the bottom, thus filling all the crevices with the descending "ice dust," which is well beaten in as the operator progresses with his work. This done, the whole is covered with sifted sawdust to the depth of 4 or 5 inches to exclude the air, following this with 2 feet thick of freshly collected leaves and a sufficient long litter to prevent the wind blowing the leaves off; and, as a "finishing touch," the rick is enclosed by hurdles, which are fastened by tarred string to stout sticks driven into the ground to keep cattle, &c., away. We use a half-inch-mesh sieve for the sawdust. The making of the ice into a "rick" instead of a "stack" is the better way, inasmuch as it obviates the question of insufficient slope arising to prevent the system being practised on that account. But the rick, as a matter of course, should be made sufficiently long to compensate for loss sustained through deficiency of height and width.

We have an excellent "ice house" here, but having so thoroughly demonstrated the fact that a good supply of ice can be had all the year round without incurring the expense of making and filling an ice-house I have ceased to make use of the one here on the score that nearly half the labour necessary to fill the house is sufficient to make a "rick" containing a like complement of ice. From a "rick" so made we have had a supply of ice for sixteen months from the date of making it. This was a test "rick," and after it was finished we had recourse to the ice house, which had been filled in the ordinary way to supplement the supplies previously obtained from the rick, but it only contained four or five loads of ice out of some 200 loads stored therein the last week the previous November, 1880. These facts go not only to conclusively prove that a supply of ice can be secured all the year round from a rick made above ground, but that in ordinary winters an "over-lap supply of four months" can also be had. In order that the openings made in the coverings of the ice rick each time that a fresh supply of ice is required may be again made air-tight, it will be advisable to send the same men on each occasion.—H. W. WARD, Longford.

STRAWBERRY PLANTS IN WINTER.

THE majority of those who grow Strawberries in pots do not begin to force them until March or thereabouts, as successful forcing in January or February is work which can only be done by those possessing the best of appliances. It is very satisfactory to have ripe Strawberries as early as possible, but plants which would only produce a very moderate crop in February would produce a heavy crop in April or May, and as a rule it is most profitable to defer forcing until the days have lengthened considerably. Previous to beginning forcing it is a bad plan to keep the plants in such a high temperature that they will never be at rest throughout the winter; keeping them growing slowly is a sure way of ruining them. The quieter and cooler they can be kept until forcing begins the better. In years gone by some of our most successful plants have been left in the open air until February. They were turned down on their sides at the end of November and laid along the bottom of a wall, where they were partially sheltered, and the roots soon became so dry that when frost came the soil did not swell and break the pots; but no harm was done to anything, and now we always allow some of our plants to be treated in this way. We also place some of them in a cool frame, and only draw the lights over them when it is severe frost or much rain. These are not kept so dry at the roots as those at the bottom of the wall, and they force almost as well, but not so early. We have put some plants into a Peach house where there was no artificial heat, but the sun heat raised the temperature so much at times that the plants showed signs of growing slightly, and as we have a decided objection to this we do not approve of storing them in Peach houses or vineries, and keep them in the

open air or in a cold frame. I have known the pots to be stacked up on each other in a large heap with the plants outwards, but except making them more convenient for covering this plan possesses no advantage over ours. One thing is certain, as long as the soil is moderately dry there is no danger of the plants being injured by frost, and no one need keep them in a high temperature during frost under the impression that they would be injured if left under its influence.—A KITCHEN GARDENER.

LOGWOOD (*HÆMATOXYLON CAMPECHIANUM*).

THIS evergreen stove plant, which attains to a moderately sized tree in South America, furnishes the logwood of commerce, and from the colour of which its name is derived—"haima," blood, and "xylon," wood. It belongs to the order of Leguminous plants, and has agreeable foliage and slender racemes of yellow flowers. It is of easy cultivation and may be readily increased from seeds, which, however, germinate more

Fig. 79.—Logwood (*Hæmatoxylon campechianum*).

freely if steeped in warm water for some hours before sowing. Cuttings of partially ripened young shoots also strike freely in sand under a bell-glass. A compost of loam, peat, and sand is suited to the requirements of this plant, with a temperature in summer of 70° to 85°, and in winter 50° to 55°.

It is a native of Campeachy, the shores of Honduras Bay, and other parts of tropical America; but it has been introduced into Jamaica, where it has become naturalised. The flowers are fragrant, and give out an agreeable odour said to resemble that of the Jonquil. The wood is hard, compact, and heavy, with a specific gravity higher than that of water; has a fine grain, and is susceptible of a fine polish. It is chiefly employed by the calico printer to give cotton a black or a brown colour; if it be dyed with an alum mordant in a decoction of logwood it becomes black. It was first cultivated in Jamaica in 1715, from seeds brought from the Bay of Campeachy, and was introduced into English gardens in 1724. Its colouring properties depend on a peculiar principle called hæmatoxylin or hæmatin.

THE PEAR CONFERENCE.

[Interim report of the Executive Committee of the National Pear Conference, held in the Royal Horticultural Society's Gardens, Chiswick, October 21st to November 4th, 1885.]

WE have received from the Secretary of the Royal Horticultural Society the following abridged statement taken from the full report of the Pear Conference recently held at Chiswick, and which is not yet suffi-

ciently advanced for publication. This extract will, however, serve the purpose of disseminating useful information to intending planters during the present season, and it is with this object that the Council have decided upon giving it the earliest possible publicity. The report has been skilfully prepared by Mr. A. F. Barron, and we shall look forward with interest to the full report whenever it is ready.

THE selection of the present season for the holding of a great Exhibition and Conference on Pears in succession to that on the Apples in 1883 proved to be especially propitious, the crops of Pears throughout the country being in general very abundant and good. The cold dry summer was not specially favourable for the growth and development of Pears, and in many instances the fruit was much smaller than usual, especially of the earlier varieties. The later varieties benefited greatly by the autumnal rains, and proved in general of a fair average character.

The response to the invitation issued by the Council proved of the most satisfactory character, the number of Pears sent in for exhibition far exceeding the most sanguine expectations of the Committee, the Exhibition being not only great in extent, but in all respect a truly representative exhibition of nearly all the varieties of Pears grown or cultivated in this country. The total number of exhibitors taking part in the Conference numbered 166, contributions being received from thirty-five of the English counties, also from Scotland, Ireland, Wales, and the Channel Islands, the total number of dishes or different lots of Pears staged numbering 6350. In addition several large and meritorious collections were received from France, which proved of great interest.

Counties.	No. of Exhibitors.	No. of Dishes.	Counties.	No. of Exhibitors.	No. of Dishes.

The total number of reputedly distinct varieties of Pears exhibited subsequent to the corrections made by the Committee amounts to 650.

An audit taken of the whole of the varieties exhibited gives the following result as to the most favoured or popular varieties, Beurré Diel, although only a second-rate Pear, standing at the top of the list, having been exhibited 194 times; Marie Louise being placed second, 155 dishes of which were shown; and Louise Bonne of Jersey third, 132.

LIST OF THE FIFTY PEARS EXHIBITED THE GREATEST NUMBER OF TIMES.

	No. of Dishes.		No. of Dishes.
Beurré Diel	194	Comte de Lamy	73
Marie Louise	155	Knight's Monarch	73
Louise Bonne of Jersey ...	132	Ne plus Meuris	73
Duchesse d'Angoulême ...	121	Beurré d'Amanlis	72
Winter Nelis	121	Beurré Superfin	70
Passe Colmar	118	Pitmaston Duchess ...	69
Josephine de Malines ...	113	Uvedale's St. Germain ...	68
Bergamotte Espéren	112	General Toddleben	67
Beurré Rance	108	Conseiller de la Cour ...	61
Catillac	108	Beurré Bosc	57
Beurré Clairgeau	106	Thompson's	56
Doyenné du Comice	103	Napoleon	55
Beurré Capiaumont	86	Marie Louise d'Uccle ...	53
Beurré d'Arenberg	80	Glou Morceau	53
Vicar of Winkfield	78	Van Mons Léon Leclerc ...	51
Chaumontel	77	Huyshe's Victoria	50
Beurré Hardy	74	Gansel's Bergamot	50
Beurré Bachelier	74	Baronne de Mello	50

In regard to nomenclature, each of the collections exhibited was carefully examined by the Committee and corrections made where considered requisite. Errors of judgment may in some cases have occurred, due to the altered appearance the same fruits often assume under different conditions, &c. Some others may have been overlooked, or their proper labels have got misplaced. Every endeavour was, however, made to secure the most correct nomenclature possible. The corrections made by

the Committee have in all cases been sent direct to the exhibitors. A pleasing feature noted by the Committee was the general correctness of the nomenclature.

On a general examination of the whole of the collections exhibited, and noting the more prominent varieties in each, the following list has been prepared—viz.,

SIXTY OF THE MOST PROMINENT VARIETIES OF PEARS EXHIBITED AT THE CONFERENCE.

Alexandre Lambre	Josephine de Malines
Bergamotte Esperen	Jersey Gratioli
Beurré Alexander Lucas	Louise Bonne of Jersey
d'Amanlis	Madame André Leroy
d'Anjou	Treyve
de l'Assomption	Marie Benoît
Bachelier	Marie Louise
Baltet, père	Marie Louise d'Uccle
Bosc	Nouvelle Fulvie
Clairgeau	Olivier de Serres
Diel	Passe Colmar
Hardy	Passe Crassane
Rance	Pitmaston Duchess
Spae	Princess
Sterckmans	Souvenir du Congrès
Superfin	Suffolk Thorn
Chaumontel	Thompson
Comte de Lamy	Urbaniste
Conseiller de la Cour	Van Mons Léon Leclerc
Doyenné Boussoch	Williams' Bon Chrétien
du Comice	Winter Nelis
Duchesse d'Angoulême	Zéphirin Grégoire
Durondeau	
Easter Beurré	STEWING PEARS.
Emile d'Heyst	Bellissime d'Hiver
Flemish Beauty	Catillac
Fondante d'Automne	Gilles d'Gilles
Gansel's Bergamot	Grosse Calebasse
General Todtleben	Uvedale's St. Germain
Glou Morceau	Verulam
Huyshes's Bergamot	Vicar of Winkfield

Of modern Pears or varieties, although not new, which are not yet in general cultivation, the Committee made the following selection, which are highly recommended for good quality both in flavour and bearing properties—viz.,

Beurré Giffard	Season August
Madame Treyve	September
Summer Beurré d'Arenberg	" "
Clapp's Favourite	" "
Pitmaston Duchess	October, November
Beurré d'Anjou	November
Beurré Baltet, père	" "
Emile d'Heyst	" "
Marie Benoist	January
Nouvelle Fulvie	" "
Beurré de Jonghe	" "
L'Inconnue (Van Mons)	" "
Duchesse de Bordeaux	February
Passe Crasanne	February, March
Olivier des Serres	" "

Varieties recommended by Committee for growing for market purposes—

Beacon	Season August
Fertility	September
Souvenir du Congrès	" "
Marie Louise d'Uccle	October, November
Durondeau or de Tongres	" "

Of new varieties, the Conference Pear exhibited by Messrs. Rivers and Son (season, October) was awarded a first class certificate.

In the collections of varieties exhibited from France, and not yet proved in this country, the Committee recommended the following as worthy of introduction:—

Beurré Dumont	October.
Madame André Leroy	November.
President Mas	" "
President d'Osmanville	" "

No list of the worthless varieties has been prepared, it being deemed sufficient in this report to notify those that are worthy of cultivation.

Without entering into comparison of the merits of the different collections exhibited, it is important to notify this fact—that the cultivation of good Pears is not confined to any particular climate or district of the country. If we take the magnificent examples from M. Cornu of Jersey as the result of good and careful cultivation, we have their equals produced by Mr. Haycock and by Mr. Thomas in Kent, and closely followed by Mr. Wildsmith in Hampshire, and Mr. Breeze in Sussex. Many other single examples throughout the exhibition were equally meritorious. No one failed to remark on the excellence of the examples from Lord Chesterfield in Herefordshire, or those further north still from Mr. Dalrymple, St. Boswells, Scotland, which were probably the most meritorious of all. Nothing contributed so much to these successful results as good and careful cultivation. As a general rule, the best fruits are produced where the greatest care is bestowed. An important factor in the successful cultivation

of the Pear is, as gathered from the returns, in the use of the Quince stock, which, from its close surface-rooting character, is more directly amenable to the attentions of the cultivator.

A general detailed report is in course of preparation, but which will necessarily take some time. This will contain the cultural and other notes supplied by the various exhibitors and the selections of varieties made by them; also a short descriptive catalogue of the whole of the varieties exhibited.—A. F. BARRON, *Secretary to the Committee.*

THOUGHTS ON CURRENT TOPICS.

MR. HIAM has again invited me to give my opinion on the cause of canker in fruit trees "quite independent of anything he has written." It is not very easy to consider this subject apart from your correspondent's views, because it is the conflict of these with established doctrines that brings the matter immediately under discussion. When casually alluding to this subject on page 422, I was inclined to think there might be something in the theory of insects causing "what is known as canker," but how much it was impossible to say, so long as evidence was withheld in support of that theory; but is Mr. Hiam's reply on page 517 evidence at all? It is the honest reiteration of his belief recorded with the best of motives, but the accuracy of his views appears only to be in some vague way confirmed by one individual who has "not actually seen the insects." So long as Mr. Hiam confines his observations to his own trees I am not in a position to say they have not been injured by insects; but as he makes a broad statement applying to trees generally that "insects are the cause of canker," I am not able to acquiesce.

THERE are hundreds of fruit trees affected with "what is known as canker," but which is really ulceration. This is caused by the punctures of insects. I had this in view when writing before, and I now find support, then quite unexpected, in the reply given to a correspondent on page 529. The question in my mind was, Are Mr. Hiam's trees ulcerated only, or really cankered? If the former he is probably right in his opinion respecting them, but if he asserts that the genuine canker of all fruit trees is "caused by insects," I am of opinion he is wrong. I prefer to rely on the causes ascribed on the page quoted. One statement embodied therein I know is true—namely, "if the subsoil be iron gravel canker is almost certain to make its appearance, however young and vigorous the trees when first planted," and the circumstances under which I gained this knowledge may be worth recording.

SOME years ago I had more to do than was pleasant with a number of young Apple trees, not a dozen or two of a few varieties, but hundreds, covering many acres of ground, embracing all the most useful varieties in cultivation. The trees were planted for commercial purposes, and perhaps no better could be had. The soil, too, appeared of the best—a reddish brown, sound, yet free-working, loam, 18 inches or more deep, and naturally drained by the gravelly brash on which it rested. The proprietor of the trees felt certain they would eventually be very profitable. For a time they grew well, producing sturdy wood that was well ripened, but in the course of four or five years canker appeared on the branches. They were fine trees then, with heads 4 to 6 feet in diameter. They were pruned, the branches doctored with strong insecticides, the soil over the roots dressed with manure, but still the scourge spread. Some we dug up, root-pruned, and replanted, but the improvement resulting was only of a temporary character. It became evident a cure was impossible. The trees were ruined, and the land sold. It was purchased by a company for extracting the abundance of iron it contained. It was full of iron, which glistened in the stones excavated. The trees I had to remove, or at least the few considered worth removal. The worst cankered roots and branches were cut away, and the trees replanted in suitable soil. They were dressed with no insecticide, yet they "grew out of the canker," and have since borne many a good crop of fruit. It was an excess of iron in the soil, and not minute insects on the branches, that caused the destruction of that great and once healthy collection of young trees. It was a lesson never to be forgotten of the importance of making sure of the real condition of the soil and subsoil before planting fruit trees extensively.

To return to the insects. There is only one way in which these, if they had "caused" the canker of the trees in their old position, did not injure those removed to the new—namely, being shaken off in transit, and I have yet to learn that fruit tree pests can be "shaken off" so easily. I have been managing and mis-managing fruit trees for nearly thirty years, and have been able to trace canker to other causes, but never satisfactorily to insects. I have seen them in cankered portions of Apple tree wood under the microscope, as I have seen others marvellously like them in the decaying wood of a gate post; but as I was not able to regard the mites as the cause of the collapse of the post, I could not consistently regard them as the originators of canker in the tree. This is my response to Mr. Hiam's invitation, and his reply shall have my respectful consideration, as, though at present I must dissent from his views, his researches are fully appreciated.

In the account of Rood Ashton Gardens on page 519, the writer informs us that Mr. Miller intends trying if a "good pail of tar" in a Peach house will keep wasps out of it. Possibly it may, but if it does not, it will, I am inclined to think, prevent the wasps eating the Peaches, because they will in all likelihood be flavoured with tar. I am not able to speak positively on that particular point, but I believe ripe fruit, as a rule, is a powerful absorbent of effluvia, including tar. I am able to state,

as a fact, that Apples, Pears, and Melons become highly flavoured with tar if any is kept in a fruit room or frame, even if the tar itself never touches the fruit. I have seen a vessel of tar placed in a Melon frame as an experiment in destroying red spider. It was only in one night, and besides injuring the foliage of the plants, some fruits approaching ripeness that were subsequently sent to the dessert table of the owner of them were returned to the gardener as "tasting of tar." They were unmistakably tar-flavoured. It is a fact also that a large quantity of Apples and Pears have been spoiled in flavour by tar having been incautiously used in a fruit room, though not a speck of it touched any of the fruit. The effluvia was simply absorbed, just as it would be absorbed by butter if tar were placed in a dairy. Tar is dangerous in plant houses also. A grower of Pelargoniums for market tarred the stages in a large house, and arranging plants on them too soon hundreds were ruined. Considering these circumstances, I certainly think tar is best kept outside any structures in which plants or fruit are kept; and if I may be allowed to do so I would suggest that a ripe Peach be placed under a large flower pot with a saucer of tar for a night, and the flavour of the fruit be tried before placing a pail of tar in a Peach house to exclude wasps.

ON the page last quoted Mr. Williamson refers to me as having "very lightly touched" on the subject of what may be termed half-pruning Vines in the autumn. I touched lightly, because I know from experience that all readers do not alike comprehend what writers intend to convey, and I did not wish to encourage any reckless slashing. On some Vines, and especially where the growths are much crowded, the leaves near the base of the laterals are next to worthless as assimilators and storers of nutriment, and to cut back the laterals too early to such so-called leaves would probably be a mistake; but in the case of well-developed and in every respect perfect leaves, I am of opinion it is quite safe to shorten the laterals just before the foliage commences changing, provided four are left on each lateral. After the leaves change it is doubtful if they store up much more food; and it is also a question if the removal of a number of them checks root-action to the prejudice of strong established Vines. I have tried the plan carefully for several years, first limiting it to one Vine the crops on which warranted an extension of the practice. I know also the plan is systematically adopted by one of the most famed Grape-growers in England, who has a brilliant record in exhibiting; also in a celebrated garden where Grapes are not grown for showing; but the crops are undeniably fine, and the gardener is admittedly one of the most able of the craft which he adorns. Still, though I and others have found the practice good, I do not advise its indiscriminate adoption, and regardless of the actual condition of the foliage, but would rather counsel others to do what I did myself—proceed cautiously and experimentally, then extend or stop procedure according to the results achieved.

I THINK the food stored by the leaves in the upper parts of Vine laterals does not benefit the lower buds which we rely on for future crops of Grapes, but is cut away. We want more nutriment storing by the lower leaves, and these should at no time be shaded, overcrowded, or weakened in their functions by the foliage above. Mr. Williamson's friend no doubt pruned his Vines too closely, and possibly too early in the season, and in that case would be certain to defeat his object.

A VERY useful hint is given on page 525 on forcing Seakale by covering the crowns with soil dug from between the rows and filling the trenches thus made with fermenting materials. Persons who are content to wait for "Kale" may have produce of the first size and finest quality without any artificial heat. Plant sets, with growths starting, a foot apart in two rows in rich deep soil in March, then have a space of 2½ feet and plant two more rows, and so on. If well tended very fine crowns will form during the summer, and these covered 7 or 8 inches deep with soil dug from between the twin rows early in the spring push through it, giving finer produce than can be had in any other way, and of a quality that cannot be surpassed. As hundreds of persons refrain from growing Seakale because they possess no means of forcing it artificially, this simple method is worth thinking about; and the more so since the Kale is ready between the seasons of winter Greens and early Peas. Large quantities of Seakale are grown in the manner described by a few individuals, but the practice is by no means so common as its merits deserve. The lighter the soil the better, and it should only be placed on the crowns when in a dry, free, workable state. The Kale is ready for cutting immediately the growths are seen pushing through the soil.

ANOTHER good hint was recorded a little time ago on growing Tuberose in a very simple manner. It appears Mr. Bell of Strathfieldsaye keeps the bulbs in paper bags till May, then plants them in good soil in the open garden, takes up the plants and pots them in the autumn, and they afford flowers plentifully under glass in the winter. It is to be remembered that Strathfieldsaye is in the south of England, and it is not to be expected that similar results are attainable everywhere; yet the experience reminds me that years ago Tuberose were started in pots towards the end of March or the beginning of April, grown under glass and prepared for planting out in June in clumps of three or five in mixed borders, and they flowered freely towards the end of summer many miles north of Hampshire. I have seen scores of them, but no one appears to have thought of lifting and potting those that were late. They would, of course, be later still by not planting till May, and then in the open ground like Potatoes, and the plan that appears to be so successful with Mr. Bell is certainly worth trying by others who covet these delightful flowers.

EVIDENCE appears to be conflicting as to the hardness and usefulness of the American novelty, the White Plume Celery, that needs no earthing. I have been so many times disappointed with sensational introductions that this variety has, as adjudicators of exhibited articles not good enough for approval euphemistically say, been "passed." I haven't grown it nor seen it, and, with all due respect to those who praise it, shall stubbornly refuse to admit its equality with the old-fashioned Celery of British gardens until I have proof of its virtues. It may be said there is no "reason" in this decision; probably there may not be, but I presume a person has a right to be incredulous, and even stubborn if he likes.

I HAVE had occasion before to say that Mr. Iggnlden is a "tough customer." When he gets anything into his head it appears a fixture. He stands to his guns on the question of what he believes the error of exhibiting late Grapes till the Chrysanthemum show season. In that case he would exclude collections of Grapes from shows until then, and then admit all the varieties; but I suppose he knows that all of them are not in the best condition even in November. His instance of a gardener showing several varieties so well in August with the approval of his employer, simply shows the gardener does his duty in endeavouring to merit that approval; and then he somewhat strangely asks what is to prevent others doing the same without the approval of those who employ them? The answer is obvious—their disapproval. That is quite sufficient. He need have no fear that if owners of vineries constructed for the purpose desire Grapes after November they will not have them. The truth is that since the exhibition of a few of the long-keeping varieties of Grapes before November a greatly increased number have been provided long after then, otherwise the prices for them in the first three months of the year would increase instead of diminish. A good many Black Hamburgs and Muscats are shown before they are even presentable, but that is no reason they should not be exhibited when they are. The whole question turns on the stipulations of schedules. Make these clear and contentions will vanish. For instance, take the Madresfield Court out of the Any other (than Black Hamburg) variety class, and assign it a class to itself, and there will be little left to grumble about; and it is observable that persons who are in the habit of winning first prizes with six or eight varieties of Grapes in August or September do not complain. The condition that three bunches of Grapes shall form a dish is to say what hundreds feel—absurd. In that I agree with our reformer; and also that a good judge would not award a prize to unripe fruit if there were ripe fruit in the same class, and otherwise good; but there is a good deal of "ripe" fruit staged that represents, if it represents anything, the reverse of good culture, and most good judges recognise the evidence of superior cultivation, which exhibitions are supposed to promote.

MR. WARD refers to my test example of judging, in which an uneven stand of Chrysanthemum blooms examined individually merited two points more than those more even in size in another stand. The same relative differences in Pears and Apples would have afforded an equally good example. Your correspondent does not say he would have awarded the first prize to the stand in which the blooms were determined after close examination to be two points inferior to the others, but observes I "allow nothing for evenness." Granted. The question is, permit me to say, not what either I or he would do in such a case, but what would be right to do under such circumstances? This is an important matter, and, with the object of testing the point I will submit that as a matter of principle everything staged should be judged on its individual merits, and that the general evenness of a number of blooms or dishes of fruit in which some varieties, even when perfect, are naturally smaller than the others, should only turn the scale when the points of merit, deduced after critical examination, are equal, it being understood that every quality is taken into consideration in the individual inspection, and that the character of each variety when fully developed is kept distinctly in mind. I think it is time some general understanding was arrived at on this question for the guidance of both exhibitors and judges, as it is clear some adjudicators attach more importance to the general evenness of collections than others do who found their awards on the merits of the individual examples in the collection, and thus exhibitors are often in doubt as to "what to be at."—A THINKER.

ROOT PROPAGATION OF BOUVARDIAS.

THIS is one of the most popular autumn and winter-flowering plants in cultivation. It is a profuse bloomer, and can be had in flower during five or six of the duldest months in the year. For cut blooms, or for plant decoration, it has few equals at this season, when flowers are in great demand in most establishments. All the varieties are easily propagated and cultivated. When well grown many of them will produce corymbs of flowers almost as large as Lilies, which stand for a long time on the plant and in a cut state before decaying.

They are propagated from cuttings of the plant and division (or cuttings) of the roots. I prefer the latter system, as the plants raised in this way grow more strongly, and are not so liable to flower prematurely as those struck from cuttings in the ordinary way. To obtain plants with strong well-ripened flowering shoots by the autumn the cuttings should be inserted by the end of February or the beginning of March. The compost we use for the cuttings consists of loam, leaf mould, and silver sand in equal parts, passed through a fine sieve, and thoroughly incorporated. In making the cuttings the soil is shook clear from the roots of the old plants, which are small and wiry; they are then cut in lengths of not more than half an inch. These are sown thickly in well-drained pots,

pans, or boxes, as the case may be, and covered to the depth of half an inch. They are then placed in a gentle heat, watered with a fine-rose pot, and covered with pieces of glass, which keep the soil moist with but little watering until they are growing.

When the plants have grown large enough they are placed into 60-size pots and kept growing under glass until the beginning of June. If the weather is favourable then they are turned out of the pots and planted in an open but sheltered position in the kitchen garden, where they will be exposed to sun and air. We plant them in rows 2 feet apart, and 20 inches asunder in the row. A little leaf-mould is mixed with the garden soil round each plant. They root freely in this, and can be lifted with fine roots in the month of September.

The summer treatment consists of watering the plants in dry weather, stopping them two or three times during the season to make them branch, and in staking the plants as they grow to prevent their being broken by wind or rain. This, and sprinkling the surface of the soil with Thomson's Vine manure occasionally, is all the labour they will require until they are potted and staked in September; after which they are placed in cool frames and kept close for a few days till they have taken with the shift. When this has been accomplished the plants can be removed to a greenhouse, and made to flower at pleasure by placing them in a gentle heat as required.—A. PETTIGREW, *Castle Gardens, Cardiff*.

[We learn from a competent judge who has seen the plants referred to that they are of unusual excellence.]

LADY BEATRICE LAMBTON PINE APPLE.

REFERRING to "D. B.'s" question regarding the successful ripening of this Pine Apple, I beg to say that I have found it necessary to entirely withhold water from its roots immediately it shows signs of ripening. Under this treatment I have some fine examples of it just now that have coloured to the crown without any sign of decay at the base. I know of no Pine Apple that is so full of juice, and the flesh of which is so melting and richly flavoured as this. In appearance and in every respect it is a noble Pine. It has, however, one fault—viz., it grows so tall where other varieties grow short and stubby, that it cannot get head room in our pits.—D. THOMSON, *Drumlaurig*.

THE PRIMULAS.

(Continued from page 467.)

PRIMULA JAPONICA, *Asa Gray*.—After ten years' failure, owing to the plants and seeds being destroyed on the homeward voyage, it was at last, through the efforts of Robert Fortune, successfully introduced early in 1871. It was first seen by him in a florist's basket near Yedo, the capital of Japan, in May, 1861, and, as he says, at once crowned by him the "Queen of Primroses." The following is the description given at the time. Its flowers are of a rich magenta colour, arranged in tiers one above another on a spike nearly 2 feet in height, with leaves not unlike our English Cowslip. On the same authority we are told that the first living seeds of this remarkable Primrose were carried in Robert Fortune's vest pocket, who, curiously enough, had a great difficulty in disposing of them, not only at his own price, but almost at any price at all. The glowing descriptions of this plant compared with the knowledge hitherto possessed of this genus looked too unreal to be taken at first hand. The seeds eventually became the property of Mr. Bull of Chelsea, who says that it was one of the best plants commercially that had ever passed through his hands. The very first year it flowered it received along with a variety called *Lilacina* a first-class certificate from the Royal Horticultural Society, since which time its popularity has only been a matter of course, and although now not so much cultivated in pots as it has been hitherto, it is yet one of the most common hardy summer decorative plants we have, an inmate of every garden, and deservedly so, as it has by now been proved to be perfectly hardy even during our most severe winters, and, indeed, the most brilliant coloured flowers we ever had the pleasure of seeing were grown from seedlings in the open air, forming tall robust specimens. It may, however, be noted that the locality is mild, the soil rather dry than otherwise, and the position partly shaded from the east and south. In low-lying or cold situations we are not so sanguine about perfect success in the open air; but if a sheltered corner be chosen, and suitable rich soil in which to grow it, we have little doubt about it ultimately. It is also largely used planted out in beds in the conservatory, more especially in the north, where it is much appreciated for this purpose, and in a few cases grown in pots for the want of beds or borders in the house. There can be little doubt about the advantage of planting out, soil and light being considered, there being a considerable saving of labour both in watering, potting, and other little attentions. Liquid manure should at first be given both weak and sparingly, gradually increasing it until the flowers begin expanding. If there be a rough semi-wild portion of the rockery choose such for *P. japonica*. It should be planted in a position 2 or 3 feet above the walk, so that the spikes will be almost on a level with the eye, a background of Lady Fern, stones, or even old decayed roots, any of which will show it to the best advantage.

The seed should be sown directly it is gathered from the plant. This saves much time and trouble, for if the seeds be kept until spring or until the outer covering has become hardened they invariably take one, two, and three years to germinate, perhaps more before all are up, whereas by sowing at the time of gathering they germinate freely in little over a fortnight, and a succession of young, fresh, vigorous plants are annually at the disposal of the grower. In some cases it may be found expedient to replace the old plants, fill up gaps, or else plant fresh colonies. As the seedlings are extremely variable the process is always interesting, when we see some with marbled or variegated leaves, others with pale, almost white, flowers, and so on, the chances being generally in favour of something good turning up in the case of large batches.

Much was said at the time of its introduction anent its hybridisation and the probable new races of Primulas we were soon to have; but we have as yet seen no hybrids, which we would fain lay to the want of application and proper material, for until a year or so ago, on the introduction of its near ally *P. prolifera*, and a year previously *P. floribunda*, we had few worthy of being matched with this gigantic species. It has been crossed with both the above, and we are anxiously awaiting the result, the more so as the hybrids so far are not typical *P. japonica*. A brief description of this popular plant may be pardoned, so as to make the series more complete. Leaves not unlike those of a robust Cowslip, almost sessile, from 3 to 6 inches long, and half as broad, between obovate and oblong, wrinkled, and generally doubly toothed, inclined to be erect in the form of a basin or nest; flower stalk from 1 to 2 feet in height, bearing from three to nine whorls of brilliant magenta or variously coloured flowers, the numbers in each whorl varying, but sometimes very numerous, an inch or more in diameter, the little pedicels as long as the flowers, and the corolla tube about three times longer than the calyx. It flowers May and June, native of Japan. It was first described by Dr. Gray in "Mem. Amer. Acad. Science," vol. vi., p. 400, from specimens collected in 1855 near Hakodadi, and afterwards collected by Maximovitz at Yokohama. Syn. *P. pyramidalis*, *Sieb.*

P. KAUFMANNIANA, *Regel*.—A comparatively new species from Turkestan, a coloured figure being given by the author in the *Flora* of that country, recently published. It has more resemblance to a Cortusa than a Primrose, and certainly distinct from any we have hitherto had in cultivation. It is said to have a marked resemblance to *P. septemloba*, differing in having more numerous lobed leaves and smooth pedicels. *P. Kaufmanniana* grows from 6 inches to a foot in height. The scape slender, with two whorls of from twelve to eighteen flowers, glossy violet, and very handsome, almost an inch broad, with a tube about the same length. The calyx is sub-campanulate, teeth lanceolate acute; the bracts at the first whorl narrow, dentate, those of the upper entire. Leaves on long stalks, orbicular in outline, with a deeply cordate base, and divided into about ten principal lobes, these being irregularly serrated, prominently veined, and, as well as the flower stalks, covered with a soft pubescence. Like our common *P. cortusoides* the leaves die entirely off during winter, leaving a little round bud. It is perfectly hardy and does well on the rockery in a rich light soil. It was found at the foot of the Almatz mountains, the top being covered with snow. It flowers April. Syn. *P. cortusoides*, *Herder*.

P. KERNERI, *Göbel and Stein*.—An interesting hybrid, *P. sub-Auricula* × *viscosa*, *Stein*, and easily cultivated in situations suitable to the Alpine *Auricula*. It was first collected by Mr. Kiegschomissar on Eisenhut, near Turrach, in Steiermark, in company with P. Göbelli underneath or near to Elm trees, and described by Stein in the "Botanik Zeitschrift" a few years ago. The leaves are light sap green, broadly spatulate or obovate, their edges serrate, dentate from the middle to the apex, and, like others of the hybrids between *Auricula*, *viscosa*, and *daonensis*, the middle or end tooth considerably larger and longer than the others. The whole plant is densely covered with short whitish hairs, having black glandular tips, those on the leaf edges being longest. Flower scape stout, an inch or two in height, carrying several large reddish violet flowers, with a whitish yellow centre. Calyx campanulate, the teeth twice longer than broad, elliptic, or nearly ovate, and pointed. Also found in Styria, flowering with us April and May.

P. LONGIFLORA, *All.*—A charming species resembling *P. farinosa* in a general way, but much larger in all its parts, and altogether a handsomer plant. The leaves are only slightly mealy underneath, much longer than those of *farinosa*, about the same shape with the exception of being a little more pointed and more irregularly notched, and not so distinctly dilated at the base. The flower stalks are much longer, nearly 1½ foot high; bracts surrounding the umbel longer and broader; the divisions of the calyx more distinctly triangular and pointed, and the corolla tube three times longer. The flowers are over half an inch in diameter, brilliant violet or violet purple, contrasting well with the sulphury dust

which almost envelopes the calyx. It is a more valuable garden plant than its near ally, and if a little more difficult to manage well it repays handsomely all the extra attention given to it. During the winter or resting season the leaves die off, leaving a little mealy ball, which will be all the better for protection with some loose material, the looser and lighter the better, so as not to engender damp, which is the greatest enemy to this gem. It belongs exclusively to the granitic regions, and should be grown in a light well-drained soil, a shallow raised pocket being the best, as it insures the water running off more rapidly. The compost we use consists of peat, leaf soil, plenty of sharp sand, a little loam, and a few pieces of granite, more particularly round the collar. Native of the grassy regions of the high Alps at elevations of from 5000 to 7000 feet above sea level. Flowering with us May and June. It ripens seed fairly well, and may be increased by this means. Syn. *P. farinosa* var., *Scop.* *P. longiflora* Krattlii, *Brugger*, 1876, said to be a hybrid between *P. farinosa* × *longiflora*, does not diminish the difficulties already existing with regard to nomenclature. *P. luteola*, *Rupr.*, is one of those free-growing Primroses that cannot be too well treated in the way of rich soil. A robust grower naturally, and when in its element one of the handsomest of the yellow-flowered kinds in cultivation. In strong specimens the flower stalks have a tendency to become fasciated, but this, instead of diminishing, adds greatly to its beauty, as it rarely fails to open all the flowers, the head being often about half a foot across. It delights in a cool clayey bottom, and may be grown in a partly shaded spot in a deep rich soil; indeed, wherever *P. Stuarti* and *sikkimensis* will do *P. luteola* will be found to thrive well.

It generally grows from a foot to 18 inches high, the stem thinly covered with golden yellow dust, terminating with a large head of sizable sulphury yellow flowers. Leaves from 3 to 6 inches long, lanceolate, having small abrupt serratures along its margins, smooth, shiny, light green. They die down during winter, leaving a large oblong bud, which may be protected with a loose material during severe frosts; otherwise it is perfectly hardy. It flowers during the spring months. Native of the Caucasus.

Syn. *P. auriculata*, *Hort.* It also does duty for *P. nivalis*, *Pall.* —D.

THE annual general meeting of the NATIONAL ROSE SOCIETY will be held, by the kind permission of the Horticultural Club, at their rooms, 1, Henrietta Street, Covent Garden, on Thursday, the 17th December, at three o'clock, for the purpose of receiving the report electing the officers and Committee for the ensuing year, confirming or otherwise the arrangements made by the General Committee for the exhibitions of 1886, and the transaction of other general business.

— AT the last meeting of the Royal Horticultural Society, several interesting hybrid *Calanthes* were shown by Sir Trevor Laurence, Bart., M.P., amongst them being *CALANTHE PORPHYREA*, which was raised in the rich collection at Burford Lodge. It was obtained from a cross between *Limatodes labrosa* and *Calanthe vestita rubro-oculata*, and while resembling the former in size and style of flower is intermediate in other respects, and superior to both in colour. The sepals and petals are small, but of an exceedingly rich crimson, very bright, the lip being lighter at the base, with numerous crimson spots and a yellowish spur. It may be remembered that another fine *Calanthe*—*Sandhurstiana*—was obtained from nearly similar parentage, *Limatodes rosea* taking the place of *L. labrosa*.

— A USEFUL plant shown and certificated at the same meeting was *CHRYSANTHEMUM BOULE DE NEIGE*, a reflexed variety, of dwarf habit, and very free flowering. The blooms are pure white, and as a late variety it will prove most valuable. Mr. R. Owen also exhibited it at the National Chrysanthemum Society's meeting on the following day, when it was again certificated.

— A CORRESPONDENT, "J. R.," will be glad if any experienced gardeners will detail their methods of filling ICE HOUSES, as the information would be of service to him, and he thinks to many other readers. Mr. Ward communicates details of an excellent method of storing ice but not in houses.

— "J. R." also asks if anyone can give information respecting an insect which is doing considerable damage amongst his potted *Hyacinths* by eating the roots. The insect somewhat resembles a large mealy bug, being quite white and about the same size and shape. He has never been troubled with it before, and thinks it is rather unusual.

— WE learn that MESSRS. WEBB & SONS of Wordsley, Stourbridge, have recently been honoured with a special Royal warrant, appointing them seedsmen to Her Most Gracious Majesty the Queen.

— A USEFUL conservatory climber is *PASSIFLORA CÆRULEA-RACEMOSA*, as it produces its purplish flowers in great profusion through the summer months. In the autumn it is almost equally attractive, as it is then laden with abundant golden yellow fruit, which set very freely. There is a fine example of this plant trained to the roof of the greenhouse at Coombe Leigh, Kingston, and at the time when Mr. Orchard had his *Chrysanthemums* in their best condition this also was highly attractive.

— SOME time ago we announced that a committee of the leading inhabitants of Bridge of Allan, N.B., had been formed to obtain funds for a TESTIMONIAL TO DR. A. PATERSON, in recognition of the service he has rendered as medical practitioner during forty years in this district. In the horticultural world Dr. Paterson is also well known as an enthusiastic and skilful cultivator of Orchids. We now learn that the subscription list is to be closed on Christmas Day, and all intending subscribers should therefore at once communicate with Mr. R. P. McCagie, Bridge of Allan, N.B.

— IN the description of new garden structures at Cleverley, on page 524, a misprint occurs in the address of MR. JOSEPH BRAMHAM, which is given as Wall Street. We learn there is no such street in Liverpool, and readily give Mr. Bramham's correct address—namely, 104 Dale Street; works, 44, Elizabeth Street, Liverpool.

— WE observe in CARTER'S VADE MECUM, just issued, that trade enterprise in offering prizes for the produce of seeds has developed into a somewhat advanced form, prizes of £10, £5, £3, £2 and £1 being offered for the best "record of the season"—that is, to exhibitors winning the greatest number of prizes at any shows in any districts. Subject to the conditions attached, the prizes are open to all "amateurs and gentlemen gardeners," which we presume means gentlemen's gardeners, but we are open to correction on the point.

— "A VISITOR" writes:—"I recently saw a GRAND DISPLAY OF EUCHARIS at Shirecliffe Hall, Sheffield. There were six plants 3 to feet across, the leaves 2 to 3 feet long, proportionately broad, dark and healthy. They were bearing scores of pure white Lily-like flowers, filling the air with their delicate fragrance. The plants were arranged with a background of large specimens of *Asparagus plumosus*, *A. plumosus nanus*, *Stevensonia grandifolia*, *Dæmonorops palembanicus*, *Croton majesticus*, *Musa Cavendishii*, and *Adiantum cardiochlaena*. I never saw a more lovely sight of its kind."

— THE usual monthly dinner and conversazione of the HORTICULTURAL CLUB took place on Tuesday last, at the rooms, 1, Henrietta Street, Covent Garden. Amongst those present were Mr. John Lee (Chairman), the Hon. and Rev. J. T. Boscawen, Dr. Masters, and Mr. Charles Eliot (Boston, U.S.A.), Dr. Hogg, the Rev. F. H. Gall, the Rev. Th. Fintoff; Messrs. C. T. Druery, Collings, Upcott Gill, G. Bunyard, H. Turner, and the Secretary. The discussion was opened by Dr. Masters on "Town Gardens, and Plants Most Suitable for Them," and a very interesting discussion arose on the subject, many of the facts brought forward by Dr. Masters being evidently new to most of those present.

— REMARKING on the DURABILITY OF WOOD CUT IN SPRING AND IN WINTER, the Editor of *Forestry* says:—"Timber cut in the spring is, according to some authorities, not so durable as that cut in winter, and recent scientific investigations appear to sustain this belief. It is shown that the richer the wood is in sulphuric acid and potassium the more liable it is to rot and mould. Wood cut in the spring months contains eight times as much of the former and five times as much of the latter as wood cut in the winter; hence it is concluded that the best time to cut down trees is winter. It would be interesting to have the opinions of experienced practical men on this point. It is a fact that trees are felled at all times from late autumn till late spring, much in accordance with convenience, custom, and other considerations. The question as to

whether the above-noticed deduction applies equally to resinous and non-resinous trees deserves special consideration."

— A PACKET of Messrs. Cassell & Co.'s publications, received a few days since, contains the following—Part 19, "Cassell's Popular Gardening," giving chapters on trees and shrubs, house and window gardening, bush fruits, stove plants, hardy fruit garden, bulbous plants and propagation, with numerous illustrations, including a frontispiece showing a group of Orchid flowers. Part 4 of "Familiar Trees" is devoted to the Apple, with coloured plate of fruit and blossom. Part 81 of "Familiar Garden Flowers" gives plates and descriptions of the Foxglove and *Deutzia gracilis*, the latter being an unsatisfactory representation of this popular plant. Part 22 of the "Encyclopædic Dictionary" contains from "Croose" to "Cyclopterus," or from page 577 to page 640. Part 19, the "Book of Health," has some useful chapters; and part 43 of "Canaries and Cage Birds" deals with miscellaneous British birds, giving a coloured plate of the Finches.

— *Nature* states that the United States botanist, "DR. ASA GRAY," was presented, on November 18th, being the seventy-fifth anniversary of his birth, with a silver vase, by the botanists of America. It is described as being about 11 inches high, and is appropriately decorated with those plants which are distinctively American, and which are most closely associated with Dr. Gray. The place of honour on one side is held by *Grayia polygaloides*, and on the other by *Shortia galacifolia*. Among others, *Aster Bigelovii*, *Solidago serotina*, *Lilium Grayi*, *Centaurea americana*, *Notholœna Grayi*, and *Rudbeckia speciosa*, are prominent. The workmanship is described as highly artistic, as well as remarkably accurate. The vase stands on a low ebony pedestal, which is surrounded by a silver hoop bearing the inscription:—"In token of the universal esteem of American botanists." The greetings by card and letter of the 180 contributors were presented on a silver tray. They contained the warmest expressions of esteem and gratitude."

— A CORRESPONDENT of the *American Gardeners' Monthly* thus describes finding in Carolina the AMERICAN CLIMBING HYDRANGEA, *DECUMARIA BARBARA*, a plant which is scarcely known in England:—"For years I had admired a climbing plant with myriads of white flat clustered flowers, which clung to the tree whereon it grew with the tenacity of Ivy, and always intended removing a small specimen to my own home, thinking it would be a good companion with my *Ampelopsis Veitchii*, which covers hundreds of feet of the brick foundation of my home. At haphazard I drove to this specimen and collected many branches, feeling sure as soon as I reached it that I had it correctly, for it having flowered in June it was filled with its seed vessels, which, according to descriptions, ought to be urn-shaped, and sure enough they are. They remind me of the old-fashioned pot-pourri pots of our grandmothers, with their queer squeezed-in little covers."

— A FRENCH nurseryman announces that one of his novelties to be sent out this season will be *PASSIFLORA VIOLACEA*, which has been recently imported from Brazil. It is said to be "one of the species described by Vellozo in his 'Flora Fluminensis,' but though well known to botanists it has never before been introduced in a living state to Europe. The petals are lilac, the outer filaments white, and the inner ones violet blue, darker at the base; the central column is green, the stigmas green spotted with purple, and the anthers are yellow."

A CAUTION TO GARDENERS.

KINDLY permit me to call the attention of my fellow practitioners to the tactics of certain unscrupulous members of the craft, who have lately in my district thought it part of their duty to endeavour to obtain a situation by a mean and despicable trick. One of these persons called at my employer's house about seven o'clock one evening, a couple of weeks ago, and on being asked by the butler to furnish his name and the nature of his business, he declined to do so, saying he wished very particularly to see my employer, mentioning his name. As my employer is an aged gentleman he refused to see the man personally, but sent his son to inquire the reasons he had for so particularly wishing to see the former. As with the butler, he was still unwilling to state his business other than to my employer, but on being told that he could not possibly see him, he naïvely said, "I hear you require a head gardener." "Nonsense," said my employer's son, "You are mistaken; our gardener is not leaving us, you must have made a mistake in the name of the place." "Oh no!" said the man, "I am sure I have not, for a friend, who knows the place well, brought me to the door. I assure you, sir, your gardener intends leaving you." "But who told you so?" "A friend from Chislehurst." "Well," said my employer's son, "all I can say, my man, is that you have made a grand mistake," and forthwith bid him good night. The next day

my employer mentioned the matter to me, but happily they repose too great a confidence in my integrity to believe that I was guilty of surreptitiously endeavouring to obtain another berth without first communicating my intention to them, therefore the would-be aspirant for my post utterly failed in the object he had in view. This state of things might, with some employers, have caused unfounded suspicions, and perhaps cost innocent gardeners the loss of good situations. A case similar to this did happen not far from here a few months ago, but happily the informant did not get the coveted post.

On inquiry I found that the person who had been trying the trick in my case was temporarily employed in a large nursery a few miles from here, and I sent him a letter through the firm requesting the names of the person who informed him that I was leaving my situation, but, as I expected, no reply has been as yet received. I may add that the firm is entirely exonerated from any knowledge or participation in such methods of procuring situations, and no one more than they regret that such methods should be adopted by men in their employ. I hope my fellow practitioners will be on their guard against such men who, stooping to such acts, are unworthy of the profession, and richly deserve a greater punishment than the publication of their misdeeds in the press.—T. W. SANDERS.

CANKER IN FRUIT TREES.

MUCH is written about canker in fruit trees. My experience on a strong soil, with clay subsoil, is head down trees afflicted with canker and graft with a strong-growing sort. Some years ago I had an old tree of Summer Orange (a local sort, good eating in September). This tree was badly cankered all round the stem. It was grafted with Warner's Seedling Apple, a strong grower. The grafts only grew on one side. This side is now quite clean. The other side is still cankered, but not so badly as it was years ago. Nothing whatever has been done to the stem to try to cure the canker, and the tree has neither been root-pruned nor manured in any way. Therefore I attribute the cure of one side entirely to the influence of the grafts, which have for several seasons borne good clean heavy cooking Apples, keeping until April and May sometimes. If Mr. J. Hiam would tell me through your paper where I can get the Cobham or Popes' Apple tree true to name he will confer a favour.—ROBERT WARNER.

MR. J. HIAM, page 517, commences with this sentence—"I am well acquainted with the fact that almost every writer is against me in my conviction that insects are the cause of canker." This may be so to a certain extent, and if he holds that they are the cause of every canker I also am against him. That they cause a form of canker I am almost positive. I hold that there are different sorts of canker (two, if not three). One I doubt not caused by imperfect drainage, and the tap root being allowed to run into cold wet clay. In my garden here (not five miles from the Liverpool Exchange) I have no such canker, not even on Ribston Pippin or Lord Suffield trees, more than ten years old. Why? Because the trees are all on red sandstone rock, which, although moist, never holds water like clay, and the tap roots cannot penetrate into them; nevertheless I have had a canker show itself on some branches of newly planted trees, caused by American blight, but this I have immediately stopped by painting the part attacked with petroleum, using an ordinary paint brush. This destroys the insects instantly without injuring the tree, and the canker does not spread. Trees once attacked by this pest should be watched, and directly there is a trace of it seen apply the petroleum and it will soon cease. The petroleum I use is the same that I burn in the lamps. Anyone having fruit trees on rock must use plenty of manure yearly if he wants a good crop of fair size fruit, whether Apples or Pears, &c. If I had heavy clay soil I should take out a good area before planting a tree, put in a good layer of brickbats, stones, &c., and under the tap root a slate, thus preventing one sort of canker at any rate; and by watching for insects and applying petroleum when they are found endeavour to do away with canker *in toto*.—L. J. W.

CHRYSANTHEMUM BELLE PAULE.

ONE of the best Japanese novelties shown this season is that of which a bloom is represented in the accompanying woodcut, fig. 80. Though a novelty to English growers it is not strictly new, having been sent out by M. Marrouch in 1881, but it does not appear to have been introduced to England until last year, when it was distributed to a few of the leading Chrysanthemum exhibitors. Mr. Molyneux succeeded in developing the characters of the variety, and two blooms staged by him in his collection of thirty-six varieties at the Crystal Palace Show, with which he won the £10 prize, was the first time it attracted prominent attention at a London exhibition. At Kingston in the following week it was again well shown by the same grower, both in the Challenge Vase collection and in the class for six blooms of one Japanese variety. The latter were wonderfully fine, and indicated the character of the variety to perfection. At this show both Mr. Molyneux and Messrs. Jackson & Son were awarded first-class certificates for it, while at a recent meeting of the National Chrysanthemum Society Mr. N. Davis of Camberwell was awarded a similar honour.

The variety has been generally shown under the name of Belle

Pauline, but M. Ghys gives the name in his list as Belle Paule, and we are informed that this was the title adopted by the raiser. The florets are long and drooping, broad, flat, or partially fluted, very distinctly margined with lilac purple on a pure white ground, a character which renders the variety most telling in a stand of blooms, especially as it is of good substance and size. Mr. Molynenx describes it as "a tall,

some seed of my selection at the Editor's request, and will gladly wait the result.

If Mr. Venus would like to send some of his to the Fruit Committee, he need have no fear in doing so, as it is not for competition, but comparison, but I will gladly wait his convenience in that matter, any time when agreeable to him will suit me.

Mr. Oliver says a few plants were selected from a seed bed and given

Fig. 80.—CHRYSANTHEMUM BELLE PAULE.

vigorous grower, and with good treatment sure to produce fine blooms." It will undoubtedly become a favourite with exhibitors, and we may expect to see it much more generally shown next season.

VENUS'S v. COOK'S EARLY CABBAGE.

I AM very glad to be able to comply with Mr. Oliver's suggestion to have the two selections fairly tried side by side, and herewith enclose

to Mr. Venus. Now, Mr. Venus told me he selected them himself from Cook's Early, after they were planted out. When I say that my selection is superior to Mr. Venus's, I do not signify they are distinct; the only difference is that my selection is more conical, consequently less liable to injury from frost and wet, being a strong point in its favour, but what I maintain is that neither of them has departed far enough from the true type to be named anything else than Cook's Early, and in this I am supported by some good old Northumberland gardeners and nurserymen who have grown Cook's ever since it was sent out. I am at one with

Mr. Oliver in saying it ought to be more widely known, as it is undoubtedly the best all-round Cabbage I know. We are cutting daily from a large square of them which have come through a series of very severe frosty nights last week, and to-day they seem as fresh and plump as before the frost, which proves it to be a very hardy Cabbage.

My chief object in writing was, if possible, to prevent this old variety being sent out under a new name, and it would be to the interest of the public if nurserymen's catalogues contained a less number of synonymous names.—DAVID INGLIS, *Howick, Lesbury, Northumberland.*

[Mr. Inglis has sent us seed, and the two stocks referred to shall be fairly tested.]

THE HORTICULTURAL OUTLOOK.

WE are fast approaching towards the end of another year, and it may not be out of place to "take stock" of what are the prospects of horticulture in the future. We know that sometimes the "unexpected happens," and it may be that the material prosperity of the country, which has shown in recent years some signs of backgoing, will now progress by leaps and bounds. This is no doubt a sanguine view of matters, and is not, I fear, very generally shared in. It will have to be conceded, I fear, that no such great improvement will take place, and there are many reasons for thinking that such is most likely. The agricultural outlook is not so bright and flourishing as it was twenty years ago. The boundless stores of other lands are now so easily transported to this country that the farmer will have to face this kind of competition, always in the future in a great degree, and even in a much greater degree than that at the present time. This means reduced rents, and consequently reduced landlord's incomes; and they in turn must be further compelled to reduce expenses, and also to try and enlarge their incomes by means which most of them in more prosperous times would not have thought of. Selling farm and garden produce is now quite common among landed proprietors, and one can hardly blame them. At the same time they are reducing working expenses in every way possible, and this means a loss to the working man. It is, indeed, true that one class cannot be independent of another, and in this present crisis the straits of certain classes are making themselves felt on all.

Those who make a living by horticultural products are of course feeling very severely the "hard times." Look for instance at the prices obtained for Grapes in Covent Garden and other markets in the country at the present time. They are simply ridiculously low. It may be urged that this is the result of over-production. No doubt this has something to do with it. But the over-production is caused more by gentlemen selling the produce of their gardens, and by the general public not giving so many dinner parties, than by the quantity produced being in excess of the demands of the nation if only trade were good and rents had not come down. At the same time, if such a state of matters is to continue some growers must go to the wall, and things will in some measure right themselves by bringing about the "survival of the fittest." This is not a pleasant prospect to contemplate, but it must be faced.

Emigration must be more and more increased if our countrymen are to find scope for trade, and also "ways and means" of living. "Greater Britain" must in the future receive from her more ancient and somewhat failing progenitor more of her sons and daughters, so that they may find room to grow and flourish, and also employment that will give them a due reward. Having had a good deal of experience in regard to sending young men abroad to grow Tea, Coffee, Cotton, &c., I may venture to advise young gardeners who have good constitutions, and are of steady and moral habits, to seek engagements in some of the quarters of the globe where there are openings for enterprise and prospects of employment which will yield a fairly good competence for after years. It must be admitted that ill times at home have also had a bad effect on the prospect of foreign enterprises too, but still there is more room for pushing young gardeners abroad than here.

Compared with sixty years ago, of course, horticulture has made such wondrous strides that almost no comparison can be made; but such enormous preparations have of late years been made to supply what till very lately appeared an ever-to-be-increasing demand for gardeners and all things required to stock gardens and carry them on, and also to supply the apparently quite unlimited public demand for fruit, flowers, and vegetables, that now, when things are either at a standstill or going back, there is a glut in the market, and produce is being disposed of at miserable prices for the vendors.

There seems no way of getting out of this difficulty but by the old rule of supply and demand, and I fear many will have to suffer in the process.—HORTUS.

CHRYSANthemum NOTES.

NATIONAL CHRYSANthemum SOCIETY.—This Society held its last floral meeting of the year on Wednesday the 9th inst., at the Royal Aquarium, when many fine blooms were exhibited. The chair was occupied by the President, Mr. E. Sanderson, and amongst other members of the Committee present were Messrs. Holmes, Ballantine, N. Davis, R. Dean, H. Cannell, Gibson, Berry, and Swift. The variety Cullingfordi again occupied the attention of the Committee, Mr. Holmes pointing out that the variety being already published in the official catalogue as a Japanese, the decision at which the Committee arrived at their last meeting might lead to some confusion. After discussing the subject at some length it was agreed to refer the matter to the General Committee. Messrs. Drover, Fareham, submitted the following blooms of Japanese

Chrysanthemums, and were awarded first-class certificates in each instance:—

White Dragon.—A large white flower, with broad florets, somewhat in way of Golden Dragon.

Bicolor.—A promising American variety of the Mons. Desbrieux type; colour reddish bronze, with distinct gold markings.

Gloriosum.—A clear bright yellow flower, with slightly twisted florets.

Messrs. Veitch & Sons were awarded first-class certificate for

Pelican.—A large white Japanese, with broad florets, also of the Dragon type.

Mr. N. Davis, Camberwell, showed a number of fine blooms, including several well-known varieties, such as Striatum and its parent Roseum Pictum, Thunberg, Boule d'Or, Sarnia, &c. The following five varieties, all Japanese, received first-class certificates.

Jackson's Duchess of Albany.—A variety much resembling Brunette; colour orange buff; a large and fine exhibition flower.

Ceres.—A large pinkish white flower, very useful as a late variety.

Japonaise.—Deep orange, with incurved florets, in way of Comte de Germany.

Mons. Burnet.—A very full flower, of a rosy peach colour.

Ville de Toulouse.—A superb flower, of the richest violet amaranth, with silvery reverse, much admired.

Messrs. Cannell & Sons showed an interesting collection of cut flowers of Chrysanthemums neatly arranged in bunches. One of the varieties, a large Anemone flower, was awarded a certificate.

Catherine-wheel.—A strikingly distinct Anemone variety, with long narrow white spreading or drooping ray florets, and a bright yellow centre.

Mr. R. Owen, Maidenhead, showed several plants of the dwarf white free-flowering reflexed flower, named Boule de Neige, which will be useful for decoration, and as such was certificated; it was also so honoured on the previous day at Kensington. The total number of certificates awarded was eleven, the largest number given at any one meeting. A vote of thanks to Messrs. Cannell and Mr. N. Davis for their exhibits brought the meeting to a close.

CHRYSANthemum CULLINGFORDI.—Considerable discussion has taken place as to this variety being classed as a reflexed or Japanese, and as far as I can see we are not likely to bring the question to a satisfactory decision by argument. I think when the matter was brought before the Floral Committee of the National Chrysanthemum Society, and it was unanimously resolved to classify it as a reflexed flower, the resolution, as far as that Society was concerned, should have decided the matter. If the Committee could not decide with flowers actually before them, it is hardly likely that they can come to any satisfactory conclusion without blooms, which probably will not be forthcoming at their next meeting, when the question is to be re-opened. I have seen a considerable number of blooms of Cullingfordi both this season and last, and I never saw a better type of a reflexed flower outside the old Christine family. Cullingfordi was simultaneously sent out from several nurseries as a reflexed flower. It was certificated by the Royal Horticultural Society, and likewise by the National Society itself as a reflexed variety. It was also reported upon by the whole of the horticultural press as a reflexed variety. The usual custom would be to follow such a unanimous decision until good cause is shown to the contrary. I venture to say that as a Japanese flower it would rarely be shown in any good stand, and would soon be put on one side like Progne, Julia Lagravère, and other favourites, simply because they are not large enough. I noted Mr. Barker's remarks, and fail to see the resemblance of Cullingfordi to Père Delaux. Has Mr. Barker got the variety correct? I rather doubt it from his description.—A GROWER.

CHRYSANthemums MRS. HEALE AND PRINCESS OF WALES.—There seems to be some confusion respecting these varieties, and perhaps my opinion may be worth recording. Mrs. Heale is as distinct from what I will call White Princess as Lord Alcester is from Golden Empress, and more so. There are two varieties of Princess of Wales in cultivation—one a rosy pink with longitudinal lines of pearl grey, petals broad at the base and tapering to the point, and shell-shaped; the upper half of this flower loses some portion of colour with age, but before it has entirely lost its distinctive colour in that respect the lower petals have turned to an absolute purple, thus rendering it practically unfit for exhibition purposes. This is what I take to be the original Princess of Wales. A very large flower is rarely seen. The other variety, which I call White Princess, and which is correctly named and described in the National Society's catalogue under that name, is a large flower, very frequently occupying a back row in good exhibition stands; it is pearly white, slightly suffused with pink in colour, petals slightly narrower at the base than the true Princess, not quite so much incurved, and semi-transparent in texture. I have grown these two varieties for six or seven consecutive years, and they have always come true to their respective characters as I have here portrayed them. Mrs. Heale is a medium-sized flower, on an average like the true Princess of Wales; the florets are as much incurved as its parent, and are about the width of those of White Princess. They are nearly opaque in texture, and vary in colour from milk white to creamy white, and have an almost imperceptible glaze on the outer surface.—A NORTHERN EXHIBITOR.

AN AMERICAN CHRYSANthemum SHOW.—The Massachusetts Chrysanthemum Show, held last month in Boston, is said to have been

very successful, being visited by 10,000 persons. One of the principal exhibitors was Dr. H. P. Walcott of Cambridge, who, besides taking numerous prizes, received certificates for several varieties. "Standing out in marked distinction with the average run of seedlings was a magnificent white reflexed flower shown by Dr. Walcott. This, which was labelled C 10, was considered the finest white seedling ever shown in Boston or anywhere else. It is a perfectly shaped globular flower, with firm strap-shaped petals of such pure colour that Elaine looks dusky beside it. The petals reflex in such a way that the flower appears to be globular, and the centre is filled to perfection. The specimen on exhibition measured over 4 inches across. It was awarded a first-class certificate of merit, and was stolen on the last night of the Exhibition by someone who no doubt hoped to propagate it from the stem."

CHRYSANTHEMUM BOULE D'OR.—A handsome bloom of this fine Japanese variety has been sent us by Mr. N. Davis of Camberwell, by whom it was also shown at the Westminster Aquarium last week in very good condition. Well-grown examples of this are most telling on an exhibition board, and as the bloom can be had of great size, it takes its place amongst the heaviest of "back row" varieties. The florets are very broad and long, the outer ones drooping and twisted, the inner ones curling and twisting in a peculiar manner, giving the bloom a remarkably distinct appearance. Though sent out by a French raiser about three years ago, it is not yet generally grown in England, but it will undoubtedly soon find a place in the best collections.

CHRYSANTHEMUM SHOW REPORTS.—The reporters of horticultural papers and their respective editors are to my mind the backbone of horticulture. What they see and communicate form the basis of our learning on all matters connected with horticulture. Flower shows would lose their chief interest if the world at large had no reports of their doings. A large number of readers will no doubt agree with me in complimenting the staff of the *Journal of Horticulture* upon the vast amount of information reported in its pages during the recent Chrysanthemum shows. In a short space of time we have had reports of shows extending over a large area—from Kent to Cornwall, and from Cornwall to Aberdeen, and to get reports of all these shows some hundreds of miles must be travelled in anything but pleasant weather. I congratulate and thank the Editor for the full information found in these pages.—N. DAVIS, *Camberwell*.

CARTER'S BRONZE QUEEN.—Calling at the Perry Hill Nurseries the other day I was interested in observing that this fine new variety is producing an abundance of cuttings, indicating that it is a "good doer." The two plants that were exhibited at the Crystal Palace, and produced blooms that were certificated by the Committee of the National Chrysanthemum Society, will be the progenitors of a sufficient number during the ensuing spring to induce the firm to distribute plants. The necessarily limited number will command a rather high price, but the variety is of such great promise that the demand is sure to be considerable.—A VISITOR.

HOT WATER AND SCALE ON FRUIT TREES.

In a recent number of the *Journal* directions were given to a correspondent for getting rid of scale on a Pear tree trained against a wall. Having a tree in the same condition, I wish to ask whether the scale may not be got rid of by syringing the tree with water hot enough to kill the scale, but not hot enough to injure the tree? I have an indistinct recollection that this plan was tried many years ago with success. It has this advantage over scraping and painting, that it is more easily applied, and by the water running down the wall at the back of the branches the scale would be killed in places where it could not well be reached for scraping and painting. If this plan is feasible I shall be glad to know what is the greatest degree of heat at which water can be safely applied to a tree in a dormant state.—AN INQUIRER.

[Possibly some of our correspondents may have tried the hot-water cure for scale and can supply the information requested.]

THE RANUNCULUS.

THE Ranunculus is one of our most beautiful old-fashioned flowers, yet it is seldom seen, though very useful for cutting, being both a good traveller and lasting several days in good condition. If cut whilst the buds are young or about a third expanded they will continue to unfold the same as if growing on the plant. A bed of the old florists' varieties is a sight to be remembered. Many gardeners no doubt are under the impression that the Ranunculus is rather fastidious. They want attention, we admit, but they only require ordinary treatment if the soil is suitable. Sandy clayey loam is the best soil, similar to that in which the common Buttercup grows freely, and if this flower flourishes in the district it may be taken for granted that the Ranunculus will thrive too if the following details are carried out.

Whilst growing the Ranunculus requires an ample supply of moisture, but it will not thrive in a close sodden soil. The position for the bed should not be in a high and dry place, or where the soil is not drained and in a well pulverised condition. The site of the bed having been marked out stir the soil deeply, and if it is poor we would sooner add some fresh loam than use manure; but if it is de-

cided to use the latter, in autumn cow manure should be dug in, not being nearer to the surface than 6 inches. The most suitable time for planting is any time after the middle of February, when the weather is favourable and the soil in a workable condition, and we would sooner wait a week than plant when the ground is in a wet state. When planting some people draw drills about 1½ inch in depth; but what we have found the quickest and best way is to make the surface of the bed level, placing an edging of thin boards around the bed, the top edge of the board to be 1½ inch above the level. Instead of drawing drills press the tubers on the surface in rows 3 inches apart and 4 inches between the rows, covering each with a pinch of sand, which will cause them to turn out clean when the time arrives for lifting. When the tubers are all laid out the soil should be levelled carefully over the tubers up to the top edge of the boards, and levelled off firmly with the back of a small rake. If those gardeners who have hitherto planted Ranunculus in drills were to adopt this plan they would not regret it, and the tubers would all be of a uniform depth.

There is one point in the preparation of the tubers before planting that needs attention, and that is to soak them in water for about twenty-four hours. When this is not done the tubers are apt to force themselves upwards too near the surface, and often out of the ground altogether, which weakens them considerably, and if not detected at once they perish, this being the cause of many failures. Another cause of failure is through the tubers not being harvested carefully, or they are stored in a damp place. A blue mould or mildew will often appear amongst them, which, if not detected at once, will soon cause serious havoc. If this should happen to appear the mouldy tubers should be picked out at once and the remainder laid out thinly in a dry place.

As the young foliage appears above the ground all weeds should be removed, and on the first dry day lightly work the surface of the bed with a small stick or fork, and press the soil lightly about the roots. All the treatment they will require is to keep them free from weeds and to give them a thorough watering occasionally if the weather prove dry. A slight mulching with well-pulverised manure would also prove beneficial and would lessen the supply of water, keeping the roots cool. When the blooms commence showing colour take care that no water touch them, as the construction of the flower causes them to hold water, and if the sun happens to shine powerfully the blooms would most likely be injured unless a shading should be provided. As the blooms fade they must be removed, or the tubers may be weakened, and as soon as the foliage turns yellow and withers lift the tubers, clear them of soil and old foliage, and lay them out to dry in the open air out of the reach of sun, or, what may be better, in an airy shed. When perfectly dry store them away. If the tubers are left in the ground after the foliage decays they are apt to commence making fresh growth or roots, which weakens them considerably.—A. YOUNG.

VALLOTA PURPUREA.

I CAN fully endorse all that Mr. Roberts says respecting the treatment of this handsome greenhouse bulb at page 524 of your last issue. Your correspondent truly says that the drying system practised by some gardeners is wrong, as after having had experience with this plant for a number of years, I am convinced that it is a mistake to allow it at any time to become dry at the roots. I have generally had the best results from plants where the bulbs were allowed to increase without being disturbed; but they are extremely useful if grown with one strong bulb in a 5-inch pot, as with good feeding they throw up a grand spike of their beautiful scarlet flowers. At one time I thought it was quite right to gradually dry them off after flowering, but now instead of that I supply them with liquid manure occasionally right through the winter, and I have every reason to be satisfied with the change of treatment.—F. H., *The Chestnuts, Walton-on-Thames*.

THE CARNATION AND PICOTEE.

"The fairest flowers o' the season
Are our Carnations and streaked Gillyflowers."

I WOULD have ventured to apologise for once more writing on this subject, if it had not been that so many people are clamorous for information about the winter management of their choice plants. I am afraid many persons do not preserve their back numbers. We value our Carnations all the more when we read that they gave exquisite pleasure to Shakespeare and so many of the ancient great and good people of centuries ago. It was evidently a favourite of Queen Elizabeth and her courtiers. Indeed, it was cultivated in England as early as the reign of Edward III., at least we would infer as much from Chaucer, the father of English poets. We also read that "many varieties of Carnations were cultivated in the time of Charles I., whose queen is reported to have been excessively fond of the flowers."

It is curious also to note the pre-eminence of the Picotee over the Carnation at one time, and anon that the flaked varieties of the Carnation were most esteemed. One would infer from Miller that Picotees were most in favour with the early florists, and that in Miller's time the flaked Carnations were preferred.

A hundred years ago flaked and bizarred Carnations were of nearly as good quality as they are now, but the Picotee did not possess the same excellence. It has been greatly improved during recent years, however. The bright golden yellow Picotee would have been a joy for ever, but it has been lost. If any grower of Picotees has the means of referring to Hogg's *Treatise on the Carnation*, sixth edition, page 58, there is a coloured plate of a fringed and not well-formed yellow Picotee. It has few good qualities to recommend it from the point of view of a modern Picotee fancier; but all will admire its rich orange yellow colour. Many varieties of this type were cultivated in England long before Hogg cultivated them so successfully in his garden at Paddington. He names as many as fifty varieties, all of which are lost to our gardens. We are told that the Empress Josephine cultivated an admirable collection of yellow Picotees in the gardens at Malmaison, also that the late Queen Charlotte and the Princesses a few years ago had a superb collection of yellow Picotees at Frogmore, which were the delight of all who saw them. The above remarks may be useful information to those who have an idea that the Carnation is quite a modern flower. Of course, one cannot judge any plant or flower either by its past or present popularity. The Carnation and Picotee must stand or fall on their own merits, although it is well not to exclude any degree of sentiment that may be attached to them.

At the present time there are many good varieties in all the sections easily to be obtained, and by ordinary care their culture presents no great difficulty. A very grave mistake which some persons make is the attempting to grow too many varieties. Exhibitors are more likely to suffer from this than those who merely grow them for cutting or garden decoration.

It is better not to grow more than about six varieties in each class or section. Thus, if we begin with the scarlet bizarres the best six are Admiral Curzon, Arthur Medhurst, George, Mars, Rayner Johnson, Robert Lord. Of crimson bizarres Harrison Weir, H. K. Mayor, John Simonite, Master Fred, Rifleman, and Shirley Hibberd. Pink and purple bizarres, Mrs. Barlow, Sarah Payne, Squire Llewelyn, Squire Penson, William Skirving, T. S. Ware. Purple flakes, Earl Stamford, Florence Nightingale, James Douglas, Mayor of Nottingham, Squire Whitbourn, and Squire Meynell. Scarlet flakes, Figaro, Henry Cannell, John Ball, Matador, Sportsman, Superb. Rose flakes, James Merryweather, Jessica, John Keet, Rob Roy, Sybil, and Tim Bobbin.

Picotees, Red-edged—Brunette, Clara, Dr. Epps, Emily, J. B. Bryant, John Smith, W. Bower, Princess of Wales, Mrs. Gorton, Thomas William, Violet, M. Douglas, William Summers. Purple-edged—Alliance, Baroness B. Coutts, Clara Penson, Her Majesty, Jessie, Mary, Mrs. A. Chancellor, Mrs. Summers, Muriel, Picco, Rev. J. B. M. Camm, and Zerlina. Rose and scarlet edged—Constance Heron, Empress Eugénie, Fanny Helen, Favourite, Miss Horner, Miss Lee, Mrs. Payne, Mrs. Webb, Mrs. Rudd, Royal Visit, Evelyn, and Mrs. Nicol.

Yellow ground Picotees—Alice, Eleanor, Flavius, Lightning, Princess Beatrice, Princess Marguerite, Prince of Orange, Ne Plus Ultra, Mrs. Colman.

The cultural remarks are simple and easily summed up. The staple should be good turfy yellow loam, but I know it is almost as easy for some people to get gold dust as good yellow loam. To those who cannot obtain it, get as good garden mould as possible, add to it a fourth or fifth part of decayed manure, some leaf mould, and sand; in case leaf mould is not obtainable, peat will do. Anyone having sufficient knowledge of potting can tell by the feel of the compost whether it is light enough for the roots to run readily through it. I like to get all the plants potted in October, a pair of plants into a large 60, or one plant into a small 60. The plants do not take long to root into the fresh potting soil, and when they are fairly rooted abundant supplies of air ought to be admitted. The lights of the frames ought to be entirely removed in fine weather; when it rains they ought to be tilted. I have grown Carnations and Picotees for many years, but have never had any plants suffer from spot, or that swelling of the stems near the surface of the soil which has been denominated gout. Green fly is troublesome, but can readily be destroyed by dusting with tobacco powder or fumigating with tobacco.—J. DOUGLAS.

FREE-FRUITING GRAPES.

LATELY some inquiries have been made about these, and I am not surprised at it, as it is quite natural that amateurs with limited knowledge

of Grape-growing should wish to secure as good a return as possible. Some may say all the best-flavoured Grapes are the most difficult to cultivate, and this may be so, as the whole of the Muscats are not easily managed successfully; but there are others by no means bad Grapes, and it is more satisfactory to grow them and have them in good condition than attempt the choicer sorts and only get fruit of a third-class character. Muscat of Alexandria, although not a shy Grape in producing bunches, is very shy in forming berries, and it may frequently be seen bearing bunches which are mere skeletons. Cannon Hall Muscat is worse still in this respect. Muscat Hamburgh is also deficient, and Madresfield Court loses so many of its berries before they gain proper maturity, that allowing it to be a good one to form bunches, it is certainly far from furnishing perfect bunches at cutting time. Gros Guillaume is very shy to produce bunches, and should never be grown unless there are practical hands to attend to it. Gros Colman produces bunches very freely. Duchess of Buccleuch, a small white Grape of exquisite flavour, is one of the best of all to produce bunches. I have counted as many as five on one side shoot. The flavour of this Grape is as good as the finest Muscat, and I am surprised it is not more grown by amateurs. Black Hamburgh is a capital variety to produce bunches, and the Black Alicante is better still. Trebbiano bunches more freely than Syrian. The Duke of Buccleuch is not a very free-bunching variety, neither is Golden Champion, as both may often be seen in the best of vineries with a few bunches on one spot and no more for a considerable distance. I know of an amateur who planted a rod of the Duke four years ago, and as yet he has not seen it produce a bunch. Some may say this must be the fault of the cultivator, and I say so too, but it only goes to prove my words that amateurs had better be contented with free-fruited Grapes of average merit than trouble with shy growers and the highest class ones when there is little chance of growing them so as to fully develop their good qualities.—A KITCHEN GARDENER.

CHRYSANTHEMUMS AND THEIR CULTURE.

PREPARING PLANTS FOR CUTTINGS.

HAVING been requested to detail my experience in cultivating these increasingly popular flowers it will be well to begin at the beginning, and this is the treatment of plants after blooming for affording the best cuttings for propagation. I regard a favourable start as being necessary to a successful finish. The foundation must be thoroughly laid to insure that success which all should strive to attain who engage in the cultivation of this flower.

When the plants have done blooming cut those varieties that are plentiful producers of cuttings down to within a few inches of the soil, but do not cut shy-growing, new, or scarce varieties lower than 2 feet above the soil, as more opportunity is then afforded for the plant to break and produce cuttings, although they are not so good in quality as those pushing from the soil or close to it, for the reason that those growing out of the hard stem are much more likely to show flower buds prematurely—often, indeed, as soon as the young plants commence growing. This should be avoided as much as possible. Still, where the variety is scarce, it sometimes happens that we must have these cuttings or none at all.

Place the pots containing the old roots or stools in any cool house as close to the glass as possible, to prevent the growths becoming drawn and consequently weak. No situation is better for them than a vinery or Peach house at rest where plenty of light can be had consequent on the foliage of the Vines or Peaches having fallen. Some growers place them in cold frames, which answers very well, except in the event of very hard frost; in that case the plants require protection, or the young growths will be injured if not spoilt, as they are very tender at this stage by reason of their having been growing a long way from the glass prior to cutting down.

Some varieties will throw up cuttings so freely as to become weakened by being crowded. When this is likely to occur thin out the weakest shoots in good time to give space to the stronger. In the case of any varieties not promising to afford a sufficient number of cuttings, loosen the surface soil, and if the roots are bare through the continual drenchings of water given previous to the plants blooming, cover the roots with light gritty soil composed principally of leaf mould and sand. Examine the drainage to make sure the plants are not waterlogged, and give occasional waterings with weak liquid manure, which will tend to strengthen the growths. Too much water applied to the roots will induce a yellow sickly growth, which must be avoided. It sometimes happens that some plants will refuse to start at all without special treatment. After correcting any defect in the drainage place such plants in gentle bottom heat, and syringe the stems occasionally. This is the only way I know of to force stubborn plants into growth. Those starting freely will not require any heat, but merely protection from frost, with plenty of air on all favourable occasions. Green fly occasionally attacks the points of the young shoots, and can easily be got rid of by fumigating with tobacco.

There are other systems adopted by growers to produce cuttings in quantity, which I will endeavour to explain as clearly as I can.

In the spring following the plants blooming inside—say in March or April—shake the old roots partly out of the soil and plant them about 3 feet apart in an open position in the garden, previously digging the ground well; but unless the soil be of a very poor description it is not wise to add much manure, as this induces strong and consequently too sappy growth. It is much better to add some fresh soil around the roots when planting, such as refuse soil from the potting bench or the materials of spent Mushroom beds, treading the soil firmly about the plants, which induces a stocky growth. Should the weather be very dry during the summer give water freely and apply a mulching of decayed manure, which dispenses with the necessity of watering so frequently when other matters press so heavily. Do not allow many shoots to extend during the summer for flowering, but only sufficient to prove the variety is true to name—an essential point, as many growths weaken the plant somewhat and overcrowd the young shoots, thus drawing them up weakly in the autumn. Should the weather not be severe during November and December good cuttings may be had, but should these be injured by frost the trouble entailed in planting out and attention during the summer is to a great extent lost. If they once get frozen they are crippled, and do not quickly recover. They can no doubt be sheltered from light frost with straw or litter; but I do not think the advantage derived by this system is adequate to the trouble entailed, as a severe frost is always likely to occur in December, and before the growths recover from its effects the best season for striking the cuttings is gone. Some varieties, notably of the Christine family, do well under this treatment; but they invariably produce good cuttings freely in the ordinary way when blooming inside.

A much better method of producing sturdy cuttings of varieties that are shy in throwing up suckers, or in the case of new varieties of which the stock is limited, is to strike the side shoots that are often produced in excess during May and June when the plants are grown for large blooms. Instead of throwing these growths or suckers away, as is usually done, insert them singly in small pots in sandy soil, plunge in a gentle bottom heat, keeping them close and shaded till rooted, then remove to a cool frame. As soon as the pots are filled with roots shift the plants into 4 or 5-inch pots, using moderately rich soil, pressing it down hard, and short stocky growths so desirable for good cuttings will be produced. Stand the plants out of doors in an open position, allowing one stem only to extend. This will attain a height of 2 to 4 feet according to the variety, and produce one bloom. Such plants are useful for decoration on the side stages of the conservatory or elsewhere. Cut them down rather early after blooming, and they will be certain to produce good suckers. I find that they always throw up more freely when grown in small pots in the manner described than when grown in the orthodox way for affording exhibition blooms, as no doubt the constant removal of the suckers during the summer treatment weakens the plants for the after-growth of cuttings. This does not occur when grown as above indicated. As the primary object is not the production of large flowers, but sturdy shoots for propagation, this is a system which I can strongly recommend as being certain to insure success.

Another system, sometimes practised by nurserymen who require cuttings in large numbers, is the following:—After cutting down the stems the roots are partly shaken out of the soil and planted thickly together in heated pits, where they can have a little bottom as well as top heat, keeping the plants close to the glass. In this manner space is economised by the removal of the large pots from the houses, but in private gardens heated pits are seldom so numerous that they can be devoted to this purpose. Gardeners, as a rule, have to adapt themselves to more economic principles, and cuttings forced in heat are not so good as those grown naturally in cool houses from the first.—E. MOLYNEUX, *Swanmore Park, Bishop's Waltham*.

(To be continued.)

CULTURE OF LISIANTHUS RUSSELLIANUS.

A CORRESPONDENT—"C. R., Ipswich"—desires information respecting the culture of this handsome plant, and as it is undeservedly neglected now we give an illustration of a specimen grown some years ago by a skilful cultivator. The cultural particulars are condensed from those which appeared in this Journal with the cut.

This beautiful and much-esteemed plant was introduced into this country in 1835 from Mexico. Being found to be capable of producing ripe seed in abundance, a large stock of plants was soon diffused among our best cultivators, who hailed it with delight. Nevertheless, strange to say, its successful cultivation, except in a few instances, still remains a desideratum—a fact amply proved by the paucity of really well-cultivated plants produced at our great metropolitan exhibitions.

Having been somewhat more successful than some of my neighbours in growing and flowering this plant, truly magnificent when well managed, I will give my plan, which is as follows:—The seed is sown early in spring, first filling a 6-inch pot half full of potsherds, over which is placed 1 inch of sphagnum moss, then filling the pot within 1 inch of the top with rich light sandy soil. When all is pressed down equal and firm, and a smooth surface made with the bottom of a small pot, sow the seed and cover it very slightly with dry white sand. Cover the pots with bell-glasses, and place them on a shelf in a shady part of an early vinery, keeping the surface constantly moist by pouring water on the outside of the glasses. As soon as the plants appear air is admitted, and increased as they advance in growth. When sufficiently strong they are pricked out into small pots, having the same drainage, moss, and mixture as the seed-pots, and are again shaded with hand or bell-glasses until the plants become established. In three weeks or a month they require to be placed singly into small pots, and encouraging their growth as much as possible by placing them in a shady part of either a vinery or Melon pit, whichever is kept at the highest temperature, with a humid atmosphere. As soon as they begin to fill their pots with roots give them once a week a little clarified liquid manure.

About the middle of August they are placed in larger pots to suit the

Fig. 81.—*Lisianthus Russellianus*.

size of the plants, in the same temperature as before, till their pots are filled with roots. After this prepare them for winter by giving them less moisture, more air, and a cooler temperature; and finally place them on a shelf near the glass, in the coolest part of the stove, and wintered rather dry. Early in February increase the heat and moisture; and as soon as they begin to grow freely replot them, which is generally about the second week in March. They receive another shift in April, and those that are intended for large specimens a third in May (using 18-inch or 20-inch pots), and a mixture consisting of equal quantities of good strong loam, peat, or bog mould, burnt clay, leaf mould, and cow manure, with a little white sand. These materials are well mixed together, and if dry are moistened to prevent their running too close in the pots. In potting a large quantity of drainage is used, and plenty of rubble stones, small potsherds, and coarse river sand amongst the mixture. Make the mixture just firm, and be very careful to leave it quite porous. Give very little water till the roots reach the sides of the pots: it is increased as the plants and the season advance, giving heat and moisture in proportion. Too much stress cannot be put upon making a proper mechanical arrangement of rich, porous, and well-drained soils, which are essential for the healthy development of plants of the nature of the *Lisianthus*.

When the young shoots have become sufficiently advanced stop them immediately above the second joint; each shoot will then produce four. They require stopping about three times. The last stopping for plants

required to bloom early should take place in the first week in June, and for plants required to bloom later, in the first week in July. As they advance in growth the branches will require to be tied out with sticks, to make round and well-formed plants.

When the plants are growing freely they are sometimes attacked with a disease at the base, which is produced by the moist and confined atmosphere that is required for their free growth. To prevent this allow the surface to become quite dry once a week, during which the plants are supplied with moisture from feeders or pans, in which the pots are placed for a few hours, being careful not to allow any stagnant water to remain about them. As soon as the blooms begin to expand keep a drier atmosphere, and expose them to more air and light, which much improves their colour.

PRUNING DENDROBES.

I WAS glad to see Mr. Prinsep bring the above matter forward once more, as it is interesting to all Orchid growers. No doubt many have tried the experiment during the past season, and I hope we shall hear the results of the practice from many different growers. Last spring I pruned several in a half-hearted kind of way—that is to say, I did not cut all growths away that had flowered, but left those of the previous year. The result with me, I am sorry to say, is far from satisfactory, for in nearly every case the growths of the past season are both shorter and weaker than the preceding ones, while on the other hand the unpruned plants have increased in both respects in a satisfactory manner; for instance, *D. Wardianum* has increased in some cases from 3½ feet to 4½ feet in length, *D. fimbriatum ocnatum* from 29 inches to 57 inches, *D. nobile* 19 inches to 29 inches, *D. Dalhousianum* from 28 inches to 43 inches, *D. fimbriatum undulatum* 17 inches to 28; in fact, scarcely any unpruned plants have failed to improve, while the pruned ones in only one or two cases have maintained their ground, but, speaking generally, have decidedly deteriorated. Perhaps the most striking instance was that of a pan of *D. chrysanthum*, which usually made growths about 4 feet long. As it was growing very strongly, I cut the whole of the old growths away after the young ones had got a start of 10 inches or 12 inches. After pruning they did not make much progress, and finally stopped at about 18 inches or 20 inches in length and flowered very poorly, but I am glad to say it is now looking as if it would make up for lost time. I am not disposed to regard my little experiments as conclusive of the failure of a system which Mr. Prinsep, and I believe some others, can practise with success; still, any further experiments, as far as I am concerned, will be on a still more limited scale than in the past.

I find *D. nobile* usually flowers on the earliest growths of the preceding year, while later growths stop until the second year. Some have bloomed from six nodes, and are now showing flower at several more, both above and below where they flowered last spring. I believe Mr. Prinsep grows his Dendrobates at a higher temperature than is usually considered necessary for them. I think he mentioned in a former communication 100° to 110°. I must say I do not like working at such high temperatures. I find 90° quite warm enough, allowing 5° or 6° extra on special occasions; and if the loss of old pseudo-bulbs must be made up by employing so much more heat I shall prefer retaining the growths, but if both are important to success, why not employ both at once?—J. J., Lancashire.

TRAINED SPECIMEN CHRYSANTHEMUMS.

ON page 491 Mr. W. Monk alludes to what I have written concerning these, and is pleased to find that "*D., Deal*," has spoken in favour of trained plants, adding, that in his opinion, "a show without good specimen plants is not worth visiting." For my part, I should not grieve if specimen Chrysanthemums, such as I imagine Mr. Monk admires, were altogether excluded from shows, and I believe many more share in this opinion. I have before stated that those trained specimens which win premier honours at good shows, represent a great amount of skill and attention, and fully deserve all that is awarded to them; but the question is, Are these specimens profitable? or, in other words, Is the amount of pleasure they give, especially to their owners, at all proportionate to the labour expended on them? What do they look like when "at home," and do they not require much more house room than they deserve? Properly set up at a show they may be effective, but who that saw them daily would not soon tire of their formality, and much prefer those ordinarily staked conservatory plants that may be made to perfect equally as fine blooms, many of which may be cut without any disfigurement.

My principal objection to providing so many classes for trained plants is the certainty of this, inducing many to attempt their culture who have neither the skill nor the convenience for bringing them to perfection, and what is more unsightly than these miserable failures with their forests of stakes, coarse unpainted ones, too, not unfrequently shabby foliage and inferior blooms? Pompons, even, we often see trained, and pretty objects they sometimes are. In the case of Japanese varieties there is now less cause for adverse criticism, as many of them lend themselves to the work, and some of the least objectionable trained specimens I have seen lately were Bouquet Fair, Madame Bertie Rendatler, Source d'Or, James Salter, Lady Selborne, Baron de Prailley, and L'Ile des Plaisirs. In this case there was abundance of bloom with few or no stakes visible, a very different state of affairs prevailing in the first-prize plants of incurved varieties staged by the same exhibitor.

We must have plants at Chrysanthemum shows, and in considerable numbers too, when a large hall has to be made attractive, but if good prizes for more naturally grown plants of each section of Chrysanthemums, as well as at least two classes for groups, were offered, the great improvement that would rapidly be accomplished would soon more than compensate for the loss of the trained specimens, and this would very probably increase the number of competitors, owing to owners of plants sharing in the approval of this method of exhibiting. I have seen nothing this season to cause me to modify my opinions as noted by Mr. Monk. At the same time public caterers must endeavour to please all classes of visitors, and for this reason it may be necessary to still offer prizes for trained plants, but let these classes be fewer in number, in order that funds may be available for those more naturally grown. So far is this mania for trained plants in the ascendant, that even the classes provided for conservatory plants are invaded by them, and at Bath, owing to there being no class to prevent it, they were awarded all the prizes in that class. It is this laxity in the framing of schedules that often leads to misunderstandings and unpleasantness. I am of opinion that groups of plants should be more encouraged, and shall not easily forget the results attending this phase of exhibiting at Kingston-on-Thames and elsewhere during the season of 1884. Every society ought to provide two classes for these, one for good-sized, and another for smaller groups. Those of a semi-circular form, with a wall for a background, should, I think, be preferred, the largest being say 10 feet by 5 feet, and the smallest 6 feet by 5 feet, but perhaps these dimensions may be improved upon. It is somewhat surprising that such a very old-established Chrysanthemum Society as that of Liverpool should still be behind the times as far as groups are concerned, and another equally as well-known old society, the Bristol or Clifton, has only quite recently offered prizes for them.—W. IGGULDEN.

REVIEW OF BOOK.

The Orchid Grower's Manual.—Sixth edition. By B. S. WILLIAMS, F.L.S. London: Victoria and Paradise Nurseries, Upper Holloway.

THIRTY-THREE years ago Mr. B. S. Williams, who had then gained considerable fame as an experienced Orchid cultivator, issued the first edition of his "*Orchid Grower's Manual*." The plain, practical, and reliable character of the instructions it contained led to a most favourable reception, though orchidists were then not nearly so numerous as now. In a comparatively short time a second edition was called for and issued; third, fourth, and fifth editions following in due course, the last being published in 1877, greatly enlarged. The past eight years have, however, seen a surprising extension of Orchid culture, large numbers of plants have been imported, many new species and varieties added to the lists, and handsome garden hybrids have been raised in this country. The beauty and interest of Orchids have been more generally recognised, and for usefulness may have obtained a place amongst the best plants grown for flower-yielding or floral decoration. The attention which Mr. C. Darwin drew to these plants a few years ago awakened the interest of the scientific world generally, and served also to render them the fashion of the age. In most gardens where the owners take a genuine interest in plants the Orchids now constitute an important part of the collection. Many gentlemen who take a special interest in them have expended fortunes in acquiring the choicest and most beautiful members of the family, while commercially the amount of money invested in them is enormous.

Taking these facts into consideration, Mr. B. S. Williams, in preparing a sixth edition of his Manual, acted wisely in determining to enlarge and improve it, so as to render it a standard work suitable to the demand for information now existing and the extent of the subject. That these objects have been satisfactorily accomplished all must admit who obtain the new edition just issued, for, while still preserving its practical character, it has also been endeavoured to render it of scientific value as a work of reference. A brief comparison of the fifth edition with the present one will show how this has been accomplished. The previous edition contained 326 pages, the present one has 659, the number of species, varieties, and hybrids described having been increased to 1470, besides giving 478 synonyms. The introduction, which now occupies ninety pages as compared with sixty in the fifth edition, has additional or much-extended chapters on "*The Season for Collecting Orchids*," "*Risks of Collecting*," "*Raising Orchids from Seeds*," "*Orchids for Room Decoration*," "*Shading Orchid Houses*," "*Growing Specimen Orchids for Exhibition*," "*Insects and Diseases*," besides the other chapters on general cultural matters comprised in the older edition, and from which any novice can gain sufficient knowledge to enable him to master the chief requirements of Orchids.

Turning to the "*Select Orchids*," we find the improvements have been numerous. Under each genus is given the essential culture, and, where some of the species need particular treatment this is described under their names. The botanical authorities are given for the names of both genera and species, while under the latter are given references to the most readily accessible works containing coloured plates. In this portion of the work Mr. T. Moore of Chelsea has rendered the author valuable assistance, which is duly acknowledged. As examples of the increase in the number of forms described we give the following genera as they occur in the two last editions. The *Aerides* have been advanced from 38 to 57; the *Angræcums* from 12 to 26; the *Anoctochilus* are only 22 as compared with 26, owing to transference of *A. Dayi* and *A. Lowi* to *Dossinia marmorata*, *A. Petola* and *A. Veitchi* to *Macodes Petola*, *A. quercicola* to *Physurus*, and other changes. *Calanthes* have increased from 14 to 25, *Cattleyas* from 100 to 161, *C. Mossiae* varieties being 35 against 28 in 1877, and *C. Trianae* varieties 18 against 7. *Celogynes* now

number 27, an increase of 12. Of *Cypripediums* 88 are described, 31 of these being hybrids, while in 1877 only 46 were enumerated. *Dendrobiums* have advanced from 98 to 132, *Epidendrums* from 28 to 39, *Lælias* from 38 to 73, *Masdevallias* from 15 to 51, *Ollontoglossums* from 69 to 145, *Oncidiums* from 78 to 95, *Phalenopsis* from 15 to 37, and *Vandas* from 20 to 38.

The illustrations have been proportionately increased—namely, from fifty-seven to 147, many of these having previously appeared in the pages of this Journal and those of our contemporaries, but Mr. Williams has added several small illustrations showing the habit of the plants in the principal genera, which, though necessarily much reduced, are clearly executed and very useful. The work is more closely printed than the former edition, but a good bold type has been employed, and the names of species are printed in small capital sideheads instead of italics as before. It has been carefully revised, a list of corrigenda at the end rectifying the majority of the slight literal errors that were passed. In recommending this work to the attention of our readers we need only add that it is well and appropriately bound in green cloth embossed with gold, forming a handsome and substantial volume, of which Mr. Williams has every reason to be proud and which every Orchid grower should possess.

ALPINE PLANTS AND THEIR CULTIVATION.

(Continued from page 491.)

THE first matter to be decided is the position of the rockery. This should be fully exposed, and not half hidden or shaded by trees above, or sufficiently near for the roots to enter the mass of soil, and so reduce it to poverty. The main bulk of the soil of which the rockery consists should be good loam, kept open by abundance of sharp sandy grit and stones. In hilly districts rockeries will not only be more easily constructed, but numerous examples will be afforded in the neighbourhood. For the sake of economy the stone of the district should be used, unless it be of a nature likely soon to crumble and decay, and where this is the case rockeries are better not attempted at all. There are many rock formations, however, which answer very well, and indeed almost any kind will suit. As to its general aspect and bearing, this remains a question of taste with the operator, but in all cases he should as closely imitate Nature as possible. Not unfrequently are huge and picturesque stones packed and cemented together in such a way as not only to be utterly out of character with the natural rock, but ruinous to the plants when placed upon them. It is not a question of how much money has been expended in making it, and which in many cases is so much squandered, but rather a question of providing suitable compartments for the plants.

There are many alpenes, and these the most brilliant and rare, that delight in being placed in sunny fissures of rock, at the same time able to send their tiny fibres deep into the earth. Herein is the secret of successful alpine culture on artificial rockeries. Too often are the so-called pockets for the reception of alpine plants shallow in the extreme, containing only a small portion of soil, and quite detached from the main body of soil, with the result that they are always satisfactory, and the ultimatum is that they dwindle and die, simply because that instead of catering for their requirements, all chance of their obtaining the necessary food has been cut off. With alpine plants in their native haunts it is a common occurrence for them to send their tiny fibres from 2 to 4 feet deep in search of the nourishment they require; thus it is where plants, even the minutest types of vegetation, exist through long-continued drought, even though they are situated on some projecting ledge which guarantees no supply of moisture for them. Melting snow and rains find their way into these narrow fissures among the fibres, and hence the supply for their needs. So in the construction of the artificial rock, let it be borne in mind that one of the greatest essentials should be providing a sufficient depth of suitable soil calculated to afford sufficient moisture for the plants even in the driest weather, and do not in any case divide your compartments, rather allow a cavity of fissure to remain open at the back, charged with soil, and in direct communication with the body below.

Without further dwelling on what might be done with rockeries on a large scale, and which, when tastefully designed and arranged, are very desirable in garden scenery, I will pass on to briefly note how the majority of these rare plants may be successfully grown in raised borders or rockery beds. Two years ago I assisted in the formation of one of these rockery borders, and having a number of plants, such as *Erinus*, *Globularias*, *Alpine Pinks*, *Edelweiss*, various species of *Primula*, *Gentiana bavarica*, that gem of *Gentians*, and many more, it was decided that a slightly raised rockery border should be made for their reception. This is the most simple means which can be employed, and at the command of all, and such as will insure success at a minimum cost. Presuming the border to be already

full of good soil, the only thing will be to get a number of stones, prior to which a few barrows or cartloads—depending on the size of the border—of rubble, small stones, broken bricks, or sharp grit, should be spread over the surface of the soil, and there worked into it. If inclined to be of a stiff retentive nature old mortar rubbish or ballast, which has been burnt, will make suitable material for keeping it open. The next thing will be to bury, or half bury, the stones, which may be done in several ways, and in some cases so that the plants may be placed against their sides. Such a border as this might be so constructed as to grow almost any alpine plant which might be placed upon it, and yet need not be more than 2 feet or 3 feet above the ordinary level. Place the stones in such a way that they will have the appearance of cropping out of the earth, and avoiding all formality of appearance. Even in dry seasons the plants will be greatly benefited by the use of the stones, which will retain a certain amount of uniformity of moisture about the roots. Some of the woolly-tufted members of *Androsace*, and other very choice plants, may for their greater preservation have some small stones placed beneath and about them to keep them from damping off at the "collar" in wet seasons. This, and such like items, will materially assist in keeping many plants through our variable winters.

This brief sketch would not be complete if I did not refer to the conditions under which alpine plants pass the winter in these snow-clad mountain regions. The reason of their refusing to pass through our ever-changing winters is this: In their native home from the end of October to the beginning or end of May, dependent on the altitude, they are continually covered with snow, and never feel the icy breeze which blows continuously across the mountains. Deeply embedded in the snow they remain dry, snug and warm throughout the entire winter, through which they pass without ever experiencing any great change in the temperature, save that of 1° or 2°, while above the snow the cold is variable and piercing in the extreme. We see that the hardships which they have seemingly to endure are as naught compared with the variable climate of England. Again, what protection can we afford these plants which can in any way equal that with which Nature covers them at home? or what can provide for them a more efficient watering than the melting snows in spring, which start them simultaneously into active vigorous life? Conditions such as these, that we cannot imitate in English gardens, conditions which keep them in check till all fear of being arrested by spring frosts and winds is past, so that they spring from their resting place and start into growth, flower, and perfect seeds in a comparatively short time; after which comes a repetition of the former winter, and the plants are again at rest. But let us notice that from the time that the plants start into growth, labouring under a bright sunny sky, with copious waterings afforded them from melting snows above, all around seems to encourage a speedy growth, and this, coupled with the perfect drainage arranged by Nature's hand, completes their success. Is it, then, to be wondered that the lover of alpenes in England cannot boast of complete success with such choice plants as the *Fairy Forget-me-not*, *Eritrichium nanum*, many of the *Gentians*, *Androsaces*, and the like, which baffle not a few of us in our attempts to grow them? I answer No; rather is it a source of greater wonder that we can collect such a vast number of precious gems from alpine floras, say from an area of 100 square miles, and bring them into a garden space here in the lowlands of the same number of yards, and induce the majority of them to endure the vicissitudes of English winters. Frost many will endure with impunity, but what they cannot endure is a sharp biting frost followed by a rapid thaw, and may be rain and frost again, all in twenty-four hours. Thus it was that for some of them I adopted a frame some years ago with bricks left out here and there, and the lights continually tilted above them, which while effectually keeping off the rains, admitted abundance of air. In this way many of the very choicest alpenes may be wintered with success. Frost and cold they will endure, but not wet.—E. JENKINS.

HARDY FRUIT GARDEN.

OLD TREES.—Attention may now be given to old fruit trees in view of seeing what can be done to improve them. We believe the term

"improve" is that which reformers and, we may add, enthusiastic young fruit-growers are wont to use in their discussions of the treatment of old fruit trees. At various periods of our life we have had all sorts of such trees under our care, and they have afforded us many a useful lesson. Among the best and most prolific of such trees we may mention a Green Gage Plum and a Peach tree, both with old hollow stems, and both bearing really fine fruit year after year. The most prolific Apricot tree we ever had was an old wide-spreading tree trained against an east wall, the bark of its stem and main branches being rugged and hard. We have in our garden now a huge standard Beurré Capiaumont Pear about 50 feet high, with a large spreading head, the stem and main branches being clothed with a thick rampant growth of Ivy; yet this tree had this year a heavy crop of many bushels of excellent fruit. It has been suggested to us that the Ivy ought to be taken off the stem, but we decidedly object to that, knowing as we do that it would do the old tree serious injury. To those who wish to improve old trees we may say, then, be cautious. If the tree is barren, see if the main roots have run deep down into a cold wet subsoil; if so, sever them from the tree; if not, leave them alone; but in either case a top-dressing of rich soil with plenty of lime in it will do good. If the branches are cumbered they may be shortened to induce fresh healthy growth, or shortened and grafted next March. We have so grafted old Pear trees with excellent results, and commend the plan. If, however, old fruit trees continue bearing fruit in every favourable season, leave stem, spur, and branch altogether alone; never mind a little crowded or misshapen growth so long as you get plenty of useful fruits. Old Peach and Nectarine trees, on the contrary, may derive much good from severe pruning if the branches are cankered and are dying. In such cases it answers best to cut down the head to within a foot or two of the stem, to shorten the roots, and to renovate the soil with sweet, fresh, rich loam. The usual result of such treatment is a sturdy robust branch growth, so vigorous as to rival that of younger trees, with which it is equally fruitful.

FRUIT FORCING.

CHERRY HOUSE.—The trees having been attended to in dressing as advised in a former calendar, the house should now be closed. The treatment should be such as will not excite growth prematurely, therefore only a slow progression should be allowed; a temperature of 40° to 45° at night and 50° in the day will need to be maintained by artificial means. When the external conditions, however, are favourable a few degrees higher may safely be permitted, but anything calculated to bring on the trees too quickly should be carefully guarded against, as undue excitement at the commencement is likely to prove injurious to the crop. Ventilation should be given at 50°, just a little at the apex to insure a change of atmosphere, ventilating freely at 55°, allowing an advance to 65° or 70° with sun, and closing at 55°. The atmospheric condition should be moderately moist, which will be attained by syringing occasionally, but an over-moist atmosphere should be avoided, and in all cases allow the trees to become dry before night. It is highly important that the borders be thoroughly moist, as when the trees are excited into growth fresh roots will speedily be formed, and to encourage them moisture is absolutely essential.

VINES.—*Late Grapes.*—Examine these at least twice a week for decayed berries, and keep the house as dry and cool as may be consistent with the safety and preservation of the fruit. When thoroughly ripe and the Vines are leafless a mean temperature of 50° is suitable until the time arrives for bottling. Anything much below this is liable to foster mould and decay; and fire heat to maintain a light temperature, especially at night, will undoubtedly cause the berries to shrivel immediately after the fall of the foliage. No further time should be lost in getting the Grape room ready for the reception of the stock of keeping Grapes, which should be cleared off the Vines not later than the first week in January, and a week's steady firing and ventilation is necessary to draw out damp and expel it. The certainty with which Grapes keep bottled for four or five months in better condition and at less expense has given confidence in a system which gives relief to the Vines, insuring that perfect rest so essential to their after well-doing. Gros Colman requires the longest time of any on the Vines, as it lays on colour after the foliage is ripe, and owing to the soft fleshy nature of the footstalks, which are liable to decay, it is best kept in the driest and warmest part of the Grape room, by which means it parts with its earthy flavour and improves in quality. To do it well it requires to be started at the beginning of February—not later—as it needs a long season of growth, and the fruit ought to be finished by the end of September.

Midseason Houses.—Pruning the Vines in these should be pushed forward, as the Vines break and show better when they have a good season of rest. The Vines should be dressed, and the house thoroughly cleansed ready for a fresh start when the proper time arrives. The loose inert surface soil also should be removed down to the roots, and a layer given 3 inches thick of fresh turfy loam, to which has been added a sprinkling of bonemeal and charred refuse. The houses should be kept cool and dry until the time arrives for closing. If they must be used for plants keep them cool, or 40° to 45° by artificial means, and as dry as practicable.

Young Pot Vines.—Those intended to be grown into fruiting canes may be cut down to a couple of eyes or close to the pots, and dressed with styptic, and placed in a succession house, which will be started early in January. Single eyes may also be placed in small pots, or in pieces of turf, and kept cool for two or three weeks before they are placed in bottom heat.

Making Vine Borders.—Where young Vines have to be planted in spring, advantage should be taken of suitable weather for mixing the

compost, and the borders made up ready for their reception. Drainage being the first essential, this part of the work must be well done. Three-inch tiles should be placed with proper fall and outlet to carry off the water passing the drainage, and if the bottom of the border be wet or the strata unfavourable it ought to be concreted, than which nothing answers better than two parts gravel and one part lime formed into a mortar-like mass. The gravel should be fine as for garden paths, or passing through an inch-mesh sieve, and should be 4 to 6 inches thick. The drainage should be clean, and not less than 9 inches thick, better a foot, coarsest at bottom and finest at the top, covering it with a layer of turves grass side downwards. Thirty inches depth of border is sufficient—i.e., of soil, which may consist of the top spit of a pasture where the soil is a medium-textured loam, light in preference to heavy, and chopped up roughly. To this add a tenth of old mortar rubbish, a twentieth of charcoal, and a fortieth part of half-inch or crushed bones, the whole thoroughly incorporated. It is advisable to keep the border well above the surrounding ground level, especially in low damp situations, and give the surface a good slope to the front, so that when covered rain and snow is thrown off. A 6-foot width will be sufficient to start with, and should be inside, the roots being confined to it by closing the apertures in the front wall, as it is advisable to have the inside border well filled with roots before admitting them to the outside one.

STRAWBERRIES IN POTS.—Forcing operations have been delayed by the severe weather, and it is useless striving to push vegetation under conditions that can only end in failure. Therefore, proceed cautiously (and there is not greater need for it than in Strawberry forcing) in frosty dull weather, allowing the temperature inside to fall corresponding to that of the outside, seeking only progress when there is sunshine or at least gleams of it, when the heat may be turned on early in the day so as to rise and maintain a temperature of 50° to 55° through the day, and the walls and paths may be damped, but only when there is a prospect of sun, so that the moisture by its action and that of a little air will have dried up before night, and the temperature should fall to its minimum of 40° to 45°. This should be continued under adverse circumstances until the new year, after which it is surprising how the plants progress with comparatively little aid. The system of starting Strawberries on beds of leaves and dung in a fermenting state is a bad practice, as it starts the roots into activity for no purpose, Nature itself being the best prompter in this respect, and unless the plants have already a sufficient quantity of roots they are unfit for forcing. It is a good plan to start an equal quantity of two kinds, so that one variety will come in after the other in successional order. Be careful to allow the plants sufficient water at the roots, examining the plants daily.

PLANT HOUSES.

Fuchsias.—A few of the plants that rested early in the season may now be started into growth for early flowering. If the plants are well formed and as large as required when grown, they should be pruned closely back, leaving only one eye or two at the most of the last season's wood. If larger plants are required the ripened wood need not be pruned so closely. The soil should be soaked with tepid water, and the plants syringed twice daily until they break into growth. If this is done the one watering will prove sufficient until they have started and are ready for potting. A good place to start these plants is an early vinery or Peach house. The remaining plants at rest in sheds and other similar positions should be protected from frost by covering them with dry straw, fern, or other material. Young autumn-struck plants now in small pots must be kept moving slowly, which they will do on a shelf close to the glass in a temperature of 45° to 50°. If this is done they will be ready early in the new year for placing into 5-inch pots.

Zonal Pelargoniums.—Plants that have become tall and ceased to flower may be placed on a shelf and kept dry at their roots for a few weeks, when they may safely be pruned and started again into growth. Others of a bushy nature, that may have discontinued flowering through use in the conservatory where the temperature is rather too low to keep them growing and flowering, should be given a light place close to the glass, and if carefully watered they will flower again freely in early spring, proving very useful for various purposes of decoration. These should occupy a moderately dry airy structure, where the night temperature can be maintained at about 45°. In order to keep conservatories gay with these plants the whole of the winter months, it is necessary to devote a house to these plants, where a moderately dry atmosphere can be maintained with a night temperature of 55°. As plants are removed from this house to the conservatory it should be refilled with others that have been reserved for the purpose in cool houses. If these plants have been carefully watered since they were housed they will be in good condition and quickly unfold their flowers in the temperature named. After these are introduced they may be watered with weak stimulants, or given an application of artificial manure on the surface of the soil. Plants to follow these as well as young stock for spring flowering should be watered with great care and kept in the temperature indicated above for those intended for flowering at that period. All plants in flower must be kept in a moderately dry atmosphere, or the flowers are liable to damp.

Heliotropes.—These plants will continue flowering more or less the whole winter if they can be given a temperature of about 50°, with a circulation of air daily whenever the weather will allow of this being done. Young stock in small pots for flowering early in the season will remain in good condition in a temperature of 40° to 45°, according to the temperature. The points of the shoots may be pinched if the plants are not sufficiently bushy, and when they have started again into growth

they will be ready for 5-inch pots and a little higher temperature if they are wanted in flower as early as possible.

Double Petunias.—These are very useful for conservatory decoration as early as they can be brought into flower, and the young plants rooted in August should now be bushy little plants in small pots. It is necessary to sort the plants prepared for this purpose, for all will not have made the same progress. The bushiest plants, if in any way backward in growth, should be placed on a shelf close to the glass, where the night temperature will not fall below 45°. They will advance slowly in this temperature, and the growth made will be sturdy and compact; they must not be at this period of the year unduly excited, or they will make weak puny growth and be ruined. The remainder can be pinched if they show signs of becoming too tall, and allow them to grow for the present under cool conditions. If these plants are sufficiently advanced until they can be placed into larger pots keep them moving and as cool as possible consistent with attaining this end.

Callas.—If wanted in flower as early as possible these may be introduced into a temperature of 55° to 60°, and they will not be long before they unfold their pure white spathes. Where these plants are well grown many spathes will be already well advanced under the cool treatment the plants are now receiving. These are highly prized for church and other forms of decoration in a cut state at Christmas. For decoration in pots for the conservatory they are really not needed until the following month if due provision is made for a late batch of *Chrysanthemums*. *Princess of Teck* is probably the best variety for this purpose in cultivation, for we shall have it this year until February has well advanced.

Solanums.—Those past their best by being employed in rooms and other not very favourable positions should now be pruned and placed in a cool house to commence growth, so that they will have a good chance to set and ripen their berries for early use another autumn. If necessary to increase the stock of these plants place them in heat, and they will soon start into growth, producing shoots suitable for cuttings. To produce good-sized well-berried plants in one season cuttings must be rooted early and grown on quickly for a time afterwards.

THE BEE-KEEPER.

SWARMING AND NON-SWARMING.

THE wisdom of coming to an early decision as to whether increase of stocks is desirable is very evident, and it is for this reason that the subject seems to be one suitable for the present time, when each one has in the dark evenings time to spare to make use of in any way which is likely to be useful. To the bee-keeper it has always been a source of constant doubt whether in the following year the apiary shall be managed on the one or the other of these very opposite systems, the principles of which are so diametrically opposed. The one allows some scope to the natural instinct of the bee, the other thwarting instinct and substituting in its place an artificial desire to gather more honey than would, if the bees were in a natural state, be gathered without throwing off a swarm, and so giving scope to the laying powers of the queen, and also providing for the perpetuation of the species. Mr. Pettigrew gave several reasons why the swarming system was the preferable mode of management, and these are so often quoted that I cannot do better than state them very briefly:—

1, The stimulus of an empty hive makes the bees work harder.

2, The combs of swarms are sweet and free from a superabundance of bee bread.

3, By swarming the number of hives is annually doubled and often trebled.

4, By the adoption of the swarming method the stocks' hives are changed every year.

5, On the non-swarming mode of management the queens grow old and die.

For these five reasons, after adding that in the swarming system there is a certainty of success, he maintains that moderate increase is desirable. I am not able altogether to agree with this great bee-master, for although great results may be obtained from either mode of management, it seems to me that if comb honey in supers or sections is desired, the absolute prevention of increase is the surest way to gain a large quantity of the best quality with the least trouble.

It may not be out of place to consider the five reasons which seemed to Mr. Pettigrew to prove the soundness of his conclusions, and so I will very briefly do so. There can be no doubt that the stimulus of an empty hive makes bees work harder than they do in the old hives, unless sufficient super room is given to the old stock at the proper time, when it is quite an open question whether a stock which has thrown a swarm can—both old stock and swarm—together produce an amount of super honey as great as a stock which, supered with judgment, is continually working freely all through the season.

With the second reason—namely, that the combs of swarms are sweet, &c.—I have no concern, for it seems to be the wiser plan at the end of every season to break up all the stocks and form sugar-fed ones for another year. Then we come to an argument apparently of great force, in that by the swarming system the number of hives is doubled and often trebled. Now, the first thought that occurs to me is, Is there a market for stocks? Can the surplus be disposed of? If not there is no reason in producing an article which is unmarketable, unless, indeed, we desire to increase our stocks, which must generally be done at the expense of comb honey. If run honey is the object, then the question bears a different aspect, and to this reference shall be made again. Another saving is effected by this method, and that is that there is no necessity to buy bees in autumn to unite to the ones with which it is proposed to form the sugar-stock, or with which to strengthen the stocks selected to stand the winter.

By the adoption of the above method the stocks are changed each year, but here again this is no argument in the mind of the man who uses sugar-fed stocks, and never keeps stocks formed from swarms. And lastly, as to the queens growing old and dying, this is a point which needs attention, but if the bee-master does as I am convinced it is wise to do—that is, strengthen each stock in autumn by a numerous addition of bees—he can very easily, if necessary, substitute a young fertile queen in the stead of the one grown old and feeble. The conclusion, then, arrived at is that for comb honey swarming must not be allowed; that the best plan to make most profit is to prevent swarming by judicious supering; each year to break up all stocks and form sugar-fed ones for the following season. The honey taken from the stocks is generally a good deal more than sufficient to pay for the sugar and the extra bees required, and the remainder is left, together with the wax, to pay for the time and labour spent in driving, feeding, &c. A stock of new sweet comb, with good patches of brood, sufficient pollen and sealed store of the healthiest description, are insured, and the seed for a bounteous harvest in the coming season is sown. Disease, if any existed, is nipped in the bud. Moths and insects are all extirpated with the least possible trouble and no expense. Why, then, shall we trouble about having swarms to provide good sweet comb for the stocks another year? Now, for the man who wants run honey, his best plan is to allow a moderate increase, a swarm and a cast, thus trebling his stocks. The swarming will gain great weight; he will have three queens laying instead of one; he will have three hives to break up at the end of the year, three hives of wax, three of honey, but the quality of the latter will be a little inferior to that run from supers which have never contained brood or pollen.

There is only one more point to which I need allude, and that is the uncertainty with which in some apiaries the attempt to prevent swarming is successful. If to prevent increase it is necessary to excise queen cells, to cut out drone comb, to examine the hives at frequent intervals, the expense and labour attendant upon such a course would deter me from endeavouring to persuade others to follow it. If by the simple means of judicious supering swarming cannot be prevented, the advocates of the modern increase method must be considered to have gained their point. Anything and everything which tends in the slightest degree to increase

the cost of production must, in the face of the continued low and still falling prices of honey, be excluded from the apiary, unless a greater amount of honey can be gained from its adoption to compensate for the increased outlay. It is impossible to impress upon the minds of bee-keepers too clearly the absolute necessity of rigid economy in every department of the apiary. That system which at least expense produces the greatest nett profit is the one which must be adopted to the exclusion of all others. If honey in one apiary can be produced at 1d. a pound less than in another, such reduced expenditure in production will enable the bee-keeper to meet the lower prices, and to dispose of his honey so as to give a reasonable profit. A penny a pound saved in production gives 1d. a pound more profit. In my opinion honey produced from stocks managed in simple hives on the non-swarming system will produce most cheaply, and will in the worst of years give some little super honey sufficient, if not to give an actual profit, at any rate to pay expenses; while in a good year a hive ready for supering at the end of April kept continuously at work until the honey season is over, without the hindrance of swarming, will produce a vastly great amount of high quality honey at less expense than a hive managed on the increase system will produce at a greater cost both of time and labour.—FELIX.

REVERSIBLE FRAMES—PERFORATED ZINC FLOORS.

I OBSERVE that you do not approve of reversible frames, but as I would like to try these for several reasons, will you kindly advise me what you consider the best frame for that purpose, and any other hint you can give for the making a suitable hive with reversible frames, so that my joiners will understand? Would you also kindly say whether perforated zinc floors are really necessary or not? As I observe the *British Bee Journal* says they do not see any necessity for them. I am desirous of studying economy as advised by "Felix" and yourself, therefore if they can be dispensed with the hives will be cheaper.—JOHN HALL.

[The hive best suited for reversible frames (the latter being of a very simple kind, which I advised some bee-keepers to try a number of years ago, when reversible frames were spoken about) differs very little from other frame hives. If a dividing board is used it must be of the sort which parts in the middle, and described in this *Journal* for Nov. 26th. The upper edges of both the front and back of the hive should be a quarter of an inch shallower than the sides; a loose piece of wood a quarter of an inch broader than the thickness of the hive makes up the space, which may be tongued into the sides, or held by two screws let into it through two cross mortices, whereby it will slide in and out so that it will come close to the ends of the frames which have no ears. A rabbit half an inch deep by one-eighth of an inch wide, so that drop slides may rest on the ends of these, may be checked or tongued so that the slide may pass freely over them. This is all the difference required from hives having ordinary frames, excepting a slide of iron let in right in the middle of both the front and back of the hive, which must not project further than a quarter of an inch. The frame, as stated, must have no ears, the top and bottom bars are the same breadth, which is a great fault. The ends of the frame will be better if slightly combered, so as to be easier of manipulation. Right in the centre of the ends of the frames nail a little cleat of wood, $1\frac{1}{2}$ long, which keeps the frames at the proper distance, and a quarter of an inch thick, serving as rests, which the frame hangs by, and five-eighths of an inch broad. This breadth secures the frames to one level on both top and bottom whichever side is uppermost, the former being level with the edge of the hive, and the latter five-eighths from the floor. This distance will be found better than anything less, as it secures a free circulation of air, and encourages the bees to build their combs down to the bottom bar. When frames are as close as a quarter of an inch to the floor, as advised by some, with the shrinkage of the hive bees are sure to be killed when the frames are being replaced after inspection. Then there is more risk of the space being blocked up with dead bees and debris of the hive than when a good depth is allowed. When bees are flying out and in, those inside form a ladder of themselves, so as to allow the active bees a free passage. The above is a hint worth taking. The foregoing plan for reversible frames, it will be observed, cannot be easily improved upon for simplicity and cheapness, the frame being a single rectangular frame easily made by anyone. In fact, I have often thought of having my ordinary frame hives made with the rests in the middle instead of the upper side, as is the case with all frame hives. Zinc floors are absolutely necessary in hives if the health and comfort of the bees are studied. Do you not observe the answerer of the query referred to in the *British Bee Journal* acknowledges he "has no knowledge" of what many bee-keepers know to be a very great de-deratum in bee hives towards successful wintering and apiculture generally? and of course, being ignorant of its benefits, does not "see the necessity of its use," and so disparages a very useful invention. But turn to page 383 of the same journal, under "Useful Hints," and read the following extract:—"After a fortnight's absence of rain, again we have a deluge. Hives are dripping—moisture inside, and alighting boards covered with dead bees

and wax chips, which have been extruded by the bees, the weather being sufficiently warm to enable them to descend from their combs and to perform their duties as scavengers. Assist the bees by removing accumulations from entrance, and permitting a free current of air to enter the hives." Had perforated zinc been employed no such disaster could have taken place so early in the year, nor would the bee-keeper be required to clear away dead bees or debris. Nothing worse can befall a hive than dampness, especially a damp floor, which chills every bee that lingers on it, and soon calls into requisition the hooked wire, which is never required in an apiary properly managed. My hives have experienced the same weather, and several weeks advanced into midwinter with weather more severe, and there are no such signs of either dead bees on the floor or dampness inside hives, nor likely to be. What would you think of me as an adviser (in the pioneer of bee-keeping) if I had to record such direful results the first month of winter? By all means use perforated zinc as floors to hives of every sort, and place no confidence in the advice of those who do not know how to manage hives so that they will be free from damp before the winter is well begun.—LANARKSHIRE BEE-KEEPER.]

TRADE CATALOGUES RECEIVED.

Hooper & Co., Covent Garden, W.—*Catalogue of New and Improved Seed Potatoes.*

Alexander E. Campbell, Cove Gardens, Gourock, N.B.—*Catalogue of Hybrid Gladioli.*

William Fell & Co.—*Catalogue of Forest Trees.*

Carter & Co., 237 and 238, High Holborn, London.—*Vade Mecum for 1886 (illustrated).*

* * All correspondence should be directed either to "THE EDITOR" or to "THE PUBLISHER." Letters addressed to Dr. Hogg or members of the staff often remain unopened unavoidably. We request that no one will write privately to any of our correspondents, as doing so subjects them to unjustifiable trouble and expense.

Correspondents should not mix up on the same sheet questions relating to Gardening and those on Bee subjects, and should never send more than two or three questions at once. All articles intended for insertion should be written on one side of the paper only. We cannot reply to questions through the post, and we do not undertake to return rejected communications.

Vine Border (*Merchant*).—If frost threatens scatter some soil or manure on the border, as the young fibres may be injured. Your letter arrived too late to be fully answered this week.

Stove Plants (*A. G. F.*).—Your letter arrived too late to be answered in our "first issue" after the receipt of your request.

Seedling Grape (*Strebler*).—Your seedling white Grape is very handsome, but we cannot quite agree with you in considering it "identical with Gros Colman, except in colour," for Gros Colman is now firm and solid, and in some cases barely ripe, while this is really past its best. It is nevertheless a very handsome Grape, and if it does prove to be a white form of Gros Colman it will be invaluable. Could you send us a bunch, or a portion of one, in February or March? or could you another year so treat the Vine as to have the fruit at that season?

Fruit at Bath and Bristol (*J. E. B.*).—We are informed the competitors in the Pear classes were not the same as at Bath. As to the relative weights of different varieties of Pears, anyone can weigh specimens who has them, and determine that point. We suspect the supplementary prize at Bath was never intended to be regarded as a reflection on the Judges. The granting of additional prizes by committees is very unusual, and the example in question ought to have no weight as a precedent. We cannot insert your letter, with two others we have received, as they would only provoke rejoinders similar in nature to some other letters we have received, and the publication of which would do no good whatever.

Nidularium Meyendorffii (*Jackson*).—The young plants you have obtained from suckers are not sufficiently advanced to colour like the old plant, but if well grown they will produce the coloured leaves before and with the flowers. There are several plants related to this one which behave in a similar manner, the brightly coloured leaves appearing only in the centre and accompanying the flowers like the bracts in many other plants. There are some species—such as the Tillandsias—which produce leaves that are permanently variegated or tessellated. The Nidularium requires to be grown in a good compost of loam and peat in a warm moist house, an ordinary plant stove being quite suitable. If you read down page 500 of our issue of December 3rd you will find two books mentioned such as you appear to require.

Bleaching Pampas Grass (*P., Surrey*).—We adopt no other plan than that described in answer to a correspondent a few weeks ago—namely, to

cut the plumes with a good length of stalk when quite dry, and before the plumes are quite clear of the sheaths, placing them in a greenhouse or other place where they will be dry, in a similar position as grown, or upright. In ten days to a fortnight they should have the leaves or grass removed and given a gentle shake; they will then open out, and have the beautiful feathery appearance for which they are so much admired. Ours dried in this way retain their beauty for at least twelve months, indeed we have some two years old still very attractive. When the sheaths are removed as soon as they signs of splitting, the plumes are whiter than when left to force off their covering in a natural manner.

Pruning Vines (H. S.).—Assuming your Vine has cast its leaves, it should be pruned at once; but we cannot tell you exactly how many eyes to cut back to, as you do not say whether the cane is one year old or more, nor give any indication of its thickness. If it has side growths or laterals, cut these off to the lowest good bud, which may be about half an inch from the main stem, and shorten the leader to about 4 feet if it is as thick as your second finger, but only leave half that length if not stouter than your little finger. If the cane is of this year's growth entirely it may be shortened to about half its length if strong; about a quarter, or even less, if weak. A Cucumber house is not the best position for a Black Hamburgh Vine, as Cucumbers require more heat and moisture than is good for Vines, especially when starting into growth. You may start the Vine in February at a temperature of 50°, raising to 55° when the growths push to half an inch, and to 60° when the leaves unfold, rising gradually to 65°, then plant your Cucumbers. If you wish these early, start the Vine a month sooner. The temperatures given are night temperatures; allow a rise of 5° by day from fire heat alone; 15° to 20° by sun heat.

Market Tomatoes (Cambridge).—Since the publication of Mr. Iggulden's Treatise on the Tomato several new varieties of Tomatoes have been introduced. Of these some of the best are Hackwood Park Prolific, Dedham Favourite, and Carter's Perfection, the last named being very handsome and superior in point of quality. At the same time, it is doubtful if either of the above sorts will supersede the good old Hathaway's Excelsior for market purposes, while the Old Red, or a good strain of it, is still extensively grown for sale. We advise you to rely principally upon Hathaway's Excelsior and Hackwood Park, giving a trial to a new sort each season in order to discover, if possible, a more profitable sort. As your house is by no means well heated it is not advisable to start very early, nothing being gained, to say the least, by it. If you sow the seed during the first week in February you ought to have strong plants ready for planting by the end of March, and these you may be able to keep growing strongly, and secure crops at a time when good prices are usually realised. They may be planted 18 inches apart, in rows not less than 3 feet asunder, in this case training them up hurdles or some kind of temporary trelliswork.

Ammoniacal Liquor (Vectis).—This liquor holds in solution sulphate of ammonia and carbonate of ammonia, and is therefore an excellent manure; but it varies considerably in strength, chiefly with the kind of coal employed in the manufacture of gas. It is also richer in ammonia in winter than in summer, because the ammonia does not escape so rapidly during the former period. It may be to a great extent fixed with gypsum, a pound being stirred in each gallon of the liquor, or with sulphuric or muriatic acid. As a rule it should be mixed with five times its quantity of water, and at this strength it is good for Vines that require assistance at the roots; but not having tried it for damping vineries after the Grapes have stoned, we are not a position to state its effects. If you contemplate using it in that way we advise you to proceed with great caution, for the liquor is more or less impregnated with tar, which is injurious in plant structures, possibly because of the coal naphtha it contains. Damage has been done to plants and Vines by coating hot-water pipes with tar. You must also remember that ammonia in excess is very injurious in vineries, and stable drainings are generally quite strong enough for that purpose. As you find sulphate of ammonia more satisfactory than the gas liquor, why not continue using it? It is one of the best of fertilisers, but even an excess of this is injurious. It is freed from impurities in the process of manufacture.

Euphorbia splendens (A. Paine).—We can understand the flowers of this plant being useless when they reach their destination if they expand in brisk heat and a close confined atmosphere. In order that the flowers may arrive perfectly fresh and last some time after they are cut from the plant they must be developed under comparatively cool conditions. If you can give the plant a temperature of 50° at night with a rise of 5° by day and a circulation of air daily when the weather will allow of this being done, we feel certain the flowers will remain fresh after they are cut. A lower temperature of 5° will do no harm; in fact, prove an advantage if maintained for a few days previous to cutting the flowers. *E. jacquinæiflora* will not remain fresh for many hours if cut from plants subject to stove heat and treatment; but when cut from plants in a temperature of 45° or 50° they will last for a very long time. We advise you when packing the flowers to place a little clean damp moss round the stems, or if you cannot obtain this any soft leaves that have been dipped in water will do very well.

Grapes Shanking (Bolton).—No doubt the shanking of your Grapes has been due mainly to a lack of support and deficient supplies of water to the Vines. Your own statement confirms this. The oystershells would do no harm, but on the contrary are good for Vines. Many break up these shells and incorporate them with the soil when making Vine borders. We scarcely understand your letter referring to the Grapes shanking after being cut. If you place the stems in bottles of water they should have kept perfectly fresh, in fact as fresh as if they had remained on the Vines. We presume you did not do this after cutting them from the Vines, and therefore they have shrivelled, for you say they were quite good when cut. We advise you when top-dressing your border to give it a good application of fresh lime—that is, if you think the soil deficient in this important ingredient. We have known Vines that have shanked badly greatly improve by a good dressing of lime. If you do not know how much lime to use, and will state the size of your border, we shall be pleased to advise you. Give your Vines more water another year, and be careful that the soil never becomes really dry, for if this is allowed the Vines are certain to suffer. You had better not pot your Pelargoniums until they show flower stems, and not then unless you wish to grow the plants into a larger size, for they will

flower for a very long time in the size pots named if you give them weak stimulants after they commence flowering. If you pot the plants they will not come into flower so early by a month or six weeks as they would in the pots in which they are now growing in. If you decide to grow them into a larger size you may pot them, provided the pots they are now in are full of roots, towards the end of next month, or early the following one, pressing the new soil firmly into the pots, so that firm sturdy growth will be the result. If you wish a flowering plant to cover the trunk of your dead tree, *Clematis flammula* would be very suitable. *Wistaria sinensis* would also do. Honeysuckle would also be very effective when once established. *Ampelopsis Veitchii*, a deciduous ornamental foliaged plant, clings naturally to almost anything; it would give no trouble in training after it once started to climb the tree.

Names of Fruits.—The names and addresses of senders of fruit to be named must in all cases be enclosed with the specimens, whether letters referring to the fruit are sent by post or not. The names are not necessarily required for publication, initials sufficing for that. (*James Pound*).—No. 6, Dr. Trousseau; 12, Amadotte; 13, Reinette de Canada; 18, Cox's Orange Pippin; 24, Winter Nelis.

Names of Plants.—We only undertake to name species of plants, not varieties that have originated from seed and termed florists' flowers. Flowering specimens are necessary of flowering plants, and Fern fronds should bear spores. Specimens should arrive in a fresh state in firm boxes. Slightly damp moss or soft green leaves form the best packing, dry cotton wool the worst. Not more than six specimens can be named at once. (*A. Reading*).—*Oncidium concolor*. (*T. B. L.*).—*Passiflora quadrangularis*. (*J. Cameron*).—You tied the names so tightly round the sprays that this, with the damp material in the box, obliterated the writing, and we can scarcely decipher the numbers. What we take to be No. 1 is *Juniperus excelsa*; 2, perhaps *Thuopsis borealis*; 4, *Juniperus chinensis*. We cannot name the others. The habits of Conifers should be stated and numbers affixed, so that they can be seen without untying the ligatures, as when damp soft paper is tightly bound round the stems it is almost impossible to remove the strips without tearing them. The fleshy-leaved plant is *Portulacaria afra*, the African Pinstripe. The Egyptian seed is *Urginea undulata*, a bulbous plant allied to the Scillas. Sow in a cool frame in spring. Your Apple trees are infested with the American blight, *Aphis lanigera*. Dress them with petroleum, rubbing it well into the fissures with a brush.

COVENT GARDEN MARKET.—DECEMBER 16TH.

BUSINESS remains the same. Some good sample of late Grapes, Gros Colman and Alicante, reaching us, making fair values. Heavy supplies of Nova Scotia Apples to hand. Kent Cobs better.

AGRICULTURAL PROGRESS.

ANNUAL Clover layers are among the things which it is highly important should be put to the test of practical utility as speedily as possible. With Wheat at 50s. or 60s. per imperial quarter, a four-course shift and annual Clover layers answered very well, but now that Wheat has apparently fallen permanently in value there will be a proportionate reduction in the area of land devoted to its culture, simply because it is unprofitable. Stern necessity presses more and more upon us the importance of rigid economy, and we are bound to inquire if we cannot do better than sow Clover

alone. On many a farm we find a practical answer to this query in the pleasant guise of the mixed herbage of alternate husbandry. There we do not find the Clovers altogether discarded. The best of them are retained—Perennial Red Clover, Alsike, Trefoil, Cow Grass, and White Clover are now mixed with such Grasses as Cocksfoot, Meadow Foxtail, Timothy, Meadow Fescue, and Perennial Rye Grass for two, three, or four years' layers, and with good culture we obtain a crop of greater bulk, nutriment, and value, and we effect a considerable saving in both men and horses. Upon farms where the husbandry has always been of a mixed character such layers found a place even before Wheat became so cheap, but in the corn-growing districts of the eastern counties Clover pure and simple is still to the fore. No doubt a few acres of Red or White Clover seed often prove very profitable; but that is a matter somewhat wide of the question, and a general recognition of the importance of mixed layers is inevitable sooner or later. We have reason to fear that the majority of farmers are slow to realise the important bearing which such changes have upon results, for so many appear content to struggle on without a thought of change or an attempt at improvement. Reductions of rent are certainly asked for and granted, but in common fairness farmers are bound to see if their system of cropping and cultivation of the soil is the best. It is not right to regard with contempt every attempt at improvement. Be very sure we all have still much to learn. This is an age of progress, and agriculture must not lag behind; only let us be careful to put each new thing to a severe test before venturing upon the application of it to practice on a large scale, and we cannot go far wrong. If we can, by means of a two or three years' layer, obtain an annual supply of nutritious fodder of even greater bulk than an ordinary Clover layer affords, and at the same time avoid fully two-thirds of the expense of cultivation over a series of years, it is obvious that the plan will make its way in spite of whatever opposition may be raised against it. Opposition? Yes, undoubtedly; for there has never been any attempt yet made for the promotion of real progress that has not been opposed in some way or other. Such opposition may not be active, it may be only passive inertia; but it exists nevertheless, and the best way to overcome it is to show results which cannot be ignored. Tangible facts are what farmers understand, yet the value of alternate husbandry, even in theory, is so palpable as to arrest the attention of every intelligent thoughtful man.

The careful selection of pure seed is another indication of progress, and we should all gladly use such seed exclusively if only our great seed merchants would be somewhat more reasonable in their charges. Surely from 80s. to 90s. per quarter for seed Wheat and Barley is altogether beside the mark in these hard times. No doubt, a certain extra outlay is involved in the cultivation and cleaning of such seed, but we confidently venture to assert that a reduction in price would lead to a much larger sale. There is no such thing possible as a monopoly of pure seeds, and the high prices at which they are now sold must tend to tempt other seedsmen to enter the field; but we certainly question the wisdom of a policy leading to such a result. By all means let us strive to procure pure seed from the best source, if only it can be had at a reasonable rate, for no matter how well we may cultivate the land, if we do not use good seed we cannot obtain really good crops. Grass seed from the hay loft and the screenings of corn have been used again and again upon the same farm, where it was by no means uncommon to hear it said that the land was not good for this or that sort of corn, or that it was unsuitable for pastures. Can we wonder that such careless slovenly practice leads to failure? There must be thoroughness in every detail of our work—drainage, ploughing, the destruction of perennial weeds, a fine seed bed, fertile soil, the best seed sown in good time, due care in harvesting the crop, in building and thatching of ricks—aye, and even in threshing and dressing the corn; everything is worthy of and must have our best attention. Care, watch-

fulness, and sound judgment are indispensable in the management of such work, the important points where error is apt to creep in and spoil our work being only learnt by experience. Corn seed, foul with the seed of Charlock and other weeds, or containing Cockles, should never be sown. Mixtures of Grass seed, whether for permanent pasture or for alternate husbandry, should always be purchased subject to analysis, for adulteration is still very prevalent.

(To be continued.)

WORK ON THE HOME FARM.

The whole of the cows and store cattle have been withdrawn from the pastures since October, and they are permanently settled in the yards for the winter. Close attention is given to the condition of both yards and lodges. The drainage of the yards is kept open so as to prevent any serious accumulation of water among the litter. Damp and sodden litter and dung is cleared out of the lodges regularly every morning, and one care taken to have plenty of dry clean litter put down for bedding. Shelter, warmth, cleanliness, with gentle kindly treatment, are of equal importance with good wholesome food and pure water. Now that the value of straw for cattle food is more clearly understood than it ever has been, it is much used without hay; straw, chaffing, root-pulping, and a mixture of the two articles of diet being the ordinary fare of store cattle. Dairy cows must not have Turnips, but a mixed diet of Carrots or Mangolds with chaff and bran. Repeatedly have we called attention to the value of bran for dairy cows in winter. We regard it as indispensable, for it is sweet, wholesome, nutritious food, and when given regularly night and morning it insures a full yield of milk. We recently tasted some butter quite unfit for use either at table or for cooking; it was bitter to the palate, and had an offensive odour, all of which was owing to an unsuitable diet. Cows often give evidence of a morbid appetite by eating foul litter saturated with filth; or if let out upon pasture late in autumn they will always eat fallen Walnut leaves if they can get at them, and then both milk and butter is spoilt. Turnips, Swedes, oil-cake, and an excessive allowance of Cabbage all spoil the milk. We cannot be too careful about this matter, and we may add that care and painstaking both in the management of the cows and in the dairy are well repaid by the excellence of all the dairy produce. There need be no uncertainty about this, for dairy management is a very simple affair, provided it is done in the right way.

The killing and curing of bacon pigs is now being done as fast as possible, a fresh batch of bacon and hams being put in pickle every month as that which is already pickled is taken to the smoking house. Pigs not required for home consumption are being sent into the market as fast as they become ready, those of compact growth being sold as porkers for the London market at from 35s. to 40s. apiece, and bacon pigs at from £4 to £5 apiece. We have purchased a considerable number of pigs at about 16s. apiece to consume inferior corn, of which we have so much just now, and they soon reach the porker size, and are then sold. We shall turn over several hundred pounds in this way before spring, and so turn all our tail or discoloured corn to profitable account.

CHICKWEED.—I think that the Chickweed seed spoken of at page 530 was probably carried by the wind. At the garden at Wisley we have a large heap of burnt rubbish ashes entirely green with Chickweed. In this case any seed in the soil must have been destroyed by fire.—GEORGE F. WILSON.

REMARKS.

6th.—Morning bright; dull after, with spots of rain.
 7th.—Generally cloudy, but bright about noon.
 8th.—Fine, bright, and cold; freezing nearly all day.
 9th.—Bright and cold; snow late in evening, about 6.1 inch deep.
 10th.—Sharp frost; fine.
 11th.—Very cold, but bright; slight fog at night.
 12th.—Fair, but a little fog; frost gone by the evening.

A week of fine dry winter weather, with skating in and round London on Friday and Saturday. Temperature about 14° below that of the preceding week, and nearly 10° below the average.—G. J. SYMONS.

1ST SUNDAY AFTER CHRISTMAS.

CHRISTMAS COGITATIONS.

CHIRSTMASTIDE is here, and is being anticipated with mingled feelings—the pleasurable, it is hoped, largely predominating. Among the incidents of the season are Christmas meetings, Christmas greetings, and—Christmas bills, these latter sometimes having a sobering tendency during a period when joyousness is supposed to prevail. Those bills for garden supplies may possibly show some diminution this year in more than one or two instances, and it is conceivable that more or less of disappointment may be experienced accordingly; yet it may be safely predicted that some of the accounts will be large enough for individuals immediately interested.

It is not to be expected that the depreciation in the value of land, which unfortunately must be admitted, will, whether it be temporary or the reverse, have no effect on the expenditure that it has been customary to devote to the maintenance of gardens. The exigencies of the times must have an impression in the direction indicated. However great the desire to indulge in what may be termed the luxuries of horticulture, other matters of importance demand attention. It were worse than useless to ignore the actualities of the present and the prospects and probable eventualities of the future. By whatever cause, or combination of causes, induced, it must be conceded that we are passing through a social revolution. As is inevitable under the circumstances, the future of gardening is contemplated with somewhat gloomy forebodings by not a few persons: others, and possibly a minority, being more sanguine in their forecasts. While they may admit a present check to progress, they have no fear of any permanent retrogression in horticultural pursuits. On the contrary, they are convinced that as year succeeds year a greater number of persons engage in gardening both as a healthy and enjoyable form of recreation and as an important factor in contributing to the comforts and necessities of life.

There can be no question that gardens have a large, and probably a larger share than at any former period, in ministering to the wants of the inhabitants of this country in the adornment of their homes and, it may be added, of themselves; and it is equally beyond dispute that garden produce in its varied forms figures very prominently among the requisites of families at all times, and more markedly and especially during such festivities as the one immediately approaching. This all gardeners know. The demands on their resources may be constantly great, but they are as a rule unusually pressing at this particular season of the year, and the thoughtful and far-seeing make the necessary preparations for affording a plentiful supply of whatever may be needed, as far as their means permit, for the requirements of the time. Without vegetables of the best quality, fruit of meritorious character, plants and flowers choice and beautiful, it is impossible the family table or festive board can be completely furnished.

And it is not in the homes of the affluent alone that

garden produce, ornamental as well as useful, is appreciated. The extraordinary market supplies show conclusively how great the general demand must be, and it is certain that the number of purchasers is greater than ever it was before. It is true the supply is equal to the requirements, and occasionally more than equal, and when that occurs the returns to the cultivators are necessarily diminished. This is to the advantage of consumers, and the only way in which producers can realise even a fair profit under those circumstances is by obtaining a greater abundance of produce from a given extent of ground or space, placing this in the markets in the best possible condition, and at a time when it is most in demand, then disposing of it quickly. Small profits and large sales will in the future have to be relied on, small sales and large profits having practically become obsolete. Some enterprising individuals recognise this, and are preparing accordingly, in full confidence that they will not be disappointed. Just as the nimble shilling is more potent than the slow half-crown in enhancing the proceeds in the form of admissions to exhibitions, and on the principle that third-class passengers are the chief contributors to railway dividends, so in the matter of commercial horticulture—the great number of small purchasers cannot be overlooked, for though their individual disbursements may be small the aggregate amount is considerable, not to say surprising, in its magnitude. There appears to be a great “levelling downwards” in the taste for flowers, fruit, and vegetables; and in the future, instead of few and heavy Christmas bills incurred in furnishing gardens, it is not unlikely that the amount devoted to that purpose will be greatly subdivided.

Gardens, there can be little doubt, will increase in numbers in the future, as will the cultivators of land generally, and this impending change, wisely arranged and prudently established, can hardly fail to result in an increased demand for seeds, roots, and plants. The present condition of things cannot be sustained. There must be an end to the sliding down of rents for land, that in some instances appear to have become as much a fashion as necessity. No man can cultivate profitably if the land is master of his capital; the capital must be master of the land, whether the extent of it be large or small, or a collapse is inevitable sooner or later.

The chief hope of horticultural prosperity rests more on the greater number of individuals that will be induced to engage in it than in any sudden return to the past order of things. The mercantile community will prove effective supporters of horticulture in the future, and the greatest expenditure will be in the form of proceeds from trade and industrial enterprise. The popular taste for gardens, plants, and flowers is, as above intimated, increasing. Orchids, Roses, and Chrysanthemums have found their way to the business centres, where their merits are discussed, and a wholesome rivalry exists among the wealthy frequenters of the great marts of industry in surpassing each other in the excellence of the produce of their gardens. The mayors and corporations of cities and towns are giving their official countenance and support to societies established for promoting high culture, and are doing their best to popularise horticulture as a pursuit fraught with benefit to rich and poor alike. This is a hopeful sign, and all who engage in promoting better cultivation in their districts are engaged in a most commendable undertaking. There is a greater thirst than ever for information on gardening matters, and at no period were there so many attentive readers of horticultural literature as at the present time. Instruction is sought for and eagerly awaited on the cultivation of plants, as well as on the management of what is regarded as more useful and profitable crops, though so great has the demand become for flowers in towns that these, regarded from a commercial point of view, are, when well grown, both “useful and profitable.”

There is little doubt that in the future gardens will not be regarded so much as ornamental appendages to homes as

for yielding something of which the value can be represented in debtor and creditor accounts. Of whatever nature the produce raised it has a commercial value, and the greater the judgment that is exercised in raising it in the best condition and at the least outlay the greater will it be to the advantage of the manager. It is from that point of view that the capacities of gardeners are being judged, and will be more closely judged in the future. Many excellent cultivators are undoubtedly heavily handicapped in the discharge of their duties. They are simply overweighted with pleasure grounds, from which no adequate compensation can be shown in figures for the labour and consequent outlay that has to be incurred in their maintenance. They may economise in fuel by forcing less early and briskly; but if lawns, flower beds, and walks must be maintained in extent and condition the life of many an excellent gardener will not be so pleasant as to the outside world it seems. This is one of the difficulties of the situation, and those gardeners will act prudently who strive to minimise them, and work as contentedly as they can till a better opportunity is afforded them for the display of their abilities.

Many first-rate cultivators are hardly pressed, and we bespeak for all earnest striving men of good character such consideration as can be fairly accorded them under the circumstances. This is not the time for changes to be lightly made. A good man, even if not perfect in all things, is not always succeeded by a better, and the imperfections of the new may prove greater than those of the old. Then, on the other hand, there is an uncertainty, and it may prove serious—namely, that of a gardener relinquishing his position because everything is not in accordance with his wishes, or because some members of his calling, and it may be less competent, are more fortunate than himself. Bitter are the regrets of many who would now rejoice in the opportunity of returning to the field of their former labour. Hard as it was to till, they have found it harder since, and their well-wishers are powerless to assist them out of difficulties that perhaps might have been avoided. Faithful work and patient waiting is a golden rule for gardeners who are longing to excel yet struggling with adverse conditions.

For young men, too, there is only one safe line of conduct—the most positive sobriety, strict attentiveness to duty, great industry, a becoming demeanour, and improving perseveringly in whatever they perceive themselves to be behind their fellows. Every student of gardening should make himself at least equal to the best in all the details of his calling. Then, and then alone, he is in a position to turn an opportunity to account, and win for himself the good position he covets and deserves; but, on the other hand, similar opportunities that come within the reach of the negligent and incompetent are only means for bringing out their shortcomings, and the result is failure—perhaps failure for life.

Glad shall we be if such failures in the future are few, and if a general improvement shall commence from the present time, when such a happy disposition exists to reconcile differences and promote feelings of goodwill in the relations of individuals of varying grades; then will there be hope that young and old, masters and men, readers and writers, will experience the pleasure embodied in the time-honoured wish that, it is hoped, may never become obsolete—

A MERRY CHRISTMAS.

HOTBEDS—HOW TO MAKE AND USE THEM.

THERE are few gardens at this time of year in which hotbeds are not being made to force early supplies of Asparagus, Potatoes, Carrots, Radishes, &c., therefore a few remarks upon the subject may be acceptable. The first thing to be done is to mix sufficient manure (as it comes from the stable yard) with an equal quantity of leaves; to make the necessary number of beds, with turning the material two or three times within ten or twelve days from the time of mixing to allow the rank heat to escape. In order to allow of the hotbeds subsiding a couple of feet they should be made 6 feet high and 2 feet

wider and longer than the frame which is to be placed thereon, but in case of a hotbed being made large enough to take two or more frames longitudinally a space of 18 inches between each will be ample. In forming the hotbeds the fermenting material should be well trodden as the work proceeds, especially so 3 feet wide along the centre, which, moreover, should be rather higher than the other parts, inasmuch as it is the hottest part of the bed, and consequently the first to decompose and subside. The ground on which the hotbed is to be made should be higher than that surrounding it, so as to prevent the accumulation of water. Having placed the frame or frames, as the case may be, on the hotbed, sufficient fermenting material to make the depth of the back part of the frame correspond with that of the front should be placed therein, following this with a couple of inches depth of decayed manure. For Potatoes and Carrots add a layer about 9 inches thick of light garden soil and leaf mould in the proportion of three parts of the former to one of the latter, mixing thoroughly therewith a few shovelfuls of fresh soot, more with a view to rendering the soil distasteful to worms and insects than fertilising it. This will result in the production of clean roots.

In making hotbeds for Melons and Cucumbers a different line of procedure must be followed, as higher bottom and top heat is necessary to promote healthy growth than is required to produce first-rate crops of Asparagus, Potatoes, Carrots, and Radishes. This being so, the hotbeds intended specially for Melons and Cucumbers should be made just large enough to hold the frame, and in making them a few layers of old Pea sticks should be placed across the beds, and with the same object in view—viz., that of communicating heat from the freshly made up linings to the interior of the bed and frame. It will be advisable to introduce a few small drain pipes in the sides and ends of the bed as it is being finished, say 6 inches from the top. When the box is placed on the bed put a shell inside it, which should be 6 inches shallower than the box. The shell can be easily made by measuring the interior of the box or frame and making it 1 inch less all round, and, as I have already stated, 6 inches shallower, nailing the battens on the outer side of the shell, so that when it is fixed in the frame there will be a space of 1 inch between that and the frame, thus supplying a means of top heat from the linings and bed. Hotbeds should be made in a southern aspect, or in front of a wall or Laurel hedge planted for the purpose of breaking the north winds. I will now show how frames on hotbeds may be profitably used by planting and sowing in them the following crops.

Potatoes now pushing into growth should be planted two days after the soil has been placed in the frame, in rows 1 foot asunder and at 7 or 8 inches apart in the rows. The frames should from that date until the Potatoes have completed their growth have sufficient air admitted to insure a sturdy growth in the haulms, without which satisfactory results will not be achieved, and as soon as they have made a few inches growth above ground a like thickness of soil should be placed between the rows. Potatoes thus planted will yield a supply of young ones fit for table about the end of April, when it should be continued from produce obtained by successional planting. They will require little, if any, water at the roots during the interval from December to April. If the soil be not considered sufficiently rich for the production of moderately good-sized tubers a sprinkling of Beeson's manure may be advantageously incorporated with it.

Similar advice is applicable to Carrots. Early Nantes Horn is the best for early use, and of this sow the soil thinly in drills about 1 inch deep and 1 foot asunder, and between these may be similarly sown rows of Wood's Frame Radish. The soil should then be closed over the seed and be made moderately firm with a board or the back of the spade. These frames, like those containing Potatoes, must have sufficient air given from the beginning to prevent their occupants making a weakly growth. A pinch of Cauliflower, Cabbage, and Lettuce seed may be sown thinly in these frames at the same time as the Carrots without in any way interfering with the welfare of the latter crop, inasmuch as the seedling plants could be pricked out in a pit containing a gentle bottom heat or under a few old lights in a sunny border as soon as they are large enough. The Radishes also will have been removed for salading before the Carrots require more room. As soon as the plants are large enough to handle they should be thinned out at 2 inches in the row, and afterwards be thinned out as required for use.

When the surface of bed becomes dry give tepid water sufficient to reach the roots. If a surfacing of soil is put over the short dung Asparagus roots can be placed closely together thereon, covered with a few inches of light soil or sifted leaf mould, then supplying tepid water to settle the soil among the roots. When the "grass" has pushed a couple of inches through the soil it should be cut and stood on the ends in a 6-inch pot resting in a saucer of water placed in a house where the temperature does not fall below 50° or 45° until required for use. When the condition of soil indicates dryness give sufficient tepid water to thoroughly moisten both soil and roots, and ventilate sufficiently from the time the Asparagus appears through

the soil until it is cut to prevent its making spindly growth. My experience of covering with a few inches thick of sifted leaf mould is that the "grass" is thereby improved in quality, being cleaner, better blanched, and crisper.

Beds which are specially made for Melons and Cucumbers should have a layer 5 or 6 inches deep of leaf mould or sawdust placed over the short dung in which to plunge 3-inch pots three parts filled with light rich mould and containing one seed each of Rollisson's Telegraph Cucumber and Highcross Hybrid Melon (which is well suited for frame cultivation) or any other approved variety. Cover the seed with a little soil and the pots with a square of glass, which, however, should be removed as soon as the plants appear, and the latter when they have made a couple of inches of growth should be top-dressed with soil of the same temperature and description as that in which they are growing, taking care in doing so not to injure the stem of the plants, which is easily done at that stage of growth by a slight pressure of the hand. Various bedding and other plants can at the same time be raised from cuttings and seed; these, however, must be removed as the Melon and Cucumber plants extend their growth. Both Melon and Cucumber plants should be planted on mounds 7 or 8 inches deep and 15 inches through in the centre of each light as soon as they have made three rough leaves and before they become root-bound in the pots. The Melon delights in a calcareous loamy soil, and the Cucumber in a light rich compost, consisting of three parts light sandy loam and one of short dung and leaf mould well mixed. In planting press the soil firmly about the roots and afterwards supply tepid water to settle the soil. Put a mixture of fresh soot and lime around each plant about 3 inches from the stems as a protection from the attacks of slugs and woodlice. This, moreover, will prevent a superabundance of moisture from settling on or about the stems of the plants, which should on being planted be kept well above the mound, especially with Melons. As the roots push through the sides of the mounds some more soil of a like temperature should be added thereto to the thickness of 3 or 4 inches, and which additions continue to make until the intervening space is filled to within a couple of inches of the summit of the miniature mounds on which the plants have been set. Take three or four leading shoots from each plant and train them regularly over the allotted space, cutting or pinching out all superfluous shoots. Stop those left when they have attained a length of 18 or 20 inches to induce them to send out fruit-bearing laterals, which may be stopped a couple of joints beyond the fruit. However, this part of the subject I must leave to be treated later on. I need hardly point out that Melons, Cucumbers, and Vegetable Marrows can be grown in frames on hotbeds previously occupied with Asparagus, Potatoes, Carrots, and Radishes during the summer and autumn months.

I may remark that the linings of Melon and Cucumber frames should be made up regularly every week or fortnight, according to the weather and the state of the fermenting material to within a couple of inches of the top of the frame, and for this purpose a good heap of fermenting dung and leaves should be kept in readiness. In making up the linings the old can either be freshened by adding thereto some fresh warm manure and leaves, or removing them and supplying fresh material over the frames at night with mats and dry fern sufficient to exclude cold as well as to prevent the internal heat escaping. Frames containing Asparagus, Potatoes, &c., will only require to have the linings made up from the top of the hotbed (where a space of 2 feet at the sides and ends is reserved as a foundation for the purpose) to the top of the frame, more with a view to keeping out the cold than to impart heat to the interior of the frame.—W. W. L.

THE FUTURE OF GARDENING AND GARDENERS.

THERE is a question which keeps pressing itself nearer and nearer to us every season, and which is probably destined soon to come on with a much greater speed, and that is—What is to become of our great private gardens and our army of professional gardeners? It says much for the class of men engaged in this work that hitherto they have against great odds been almost able to keep up appearances as of old, and to make ends, if not to meet, at least to come within a "measurable distance" of doing so. But does anyone suppose that this state of things can continue?

A dozen years or more ago when the country was in great prosperity a large amount of money was spent in gardening, and what was called gardening. Some of it certainly deserved another name, but I suppose it pleased those who found the money, and we had no right to grumble, although our taste often rebelled. Well, in those prosperous times even the head of a large gardening establishment had to work very hard, and it was no easy task to keep abreast of his duties. He never found he had more men than he knew what to do with if they were good ones, and he was fortunate indeed if he could not during the spring months at least see a fortnight's work waiting to be done.

The times changed, bad seasons came. But bad seasons had come before, and good ones had followed, bringing prosperity in their wake. There was, however, a succession of bad seasons, and agriculturists who, by-the-by, had grown somewhat luxurious in their prosperity, could not pay their way, and the great landowners speedily found the consequences. One of the luxuries of this class is their gardens, and many of them quickly decided to curtail their expenditure in this direction, and they were perfectly justified in doing so. But how do we find they set about it? A case within my own knowledge will, I am afraid, answer for many more. "Brown," says the Squire, "I see my garden expenses for the last year were over £1000!" "Yes sir, what are called garden expenses did reach that amount, but at least one-third of it ought to be debited to other parts of your establishment. For the *bona fide* garden expenses you have certainly had the worth of your money in the keeping of the flower gardens, pleasure grounds, the kitchen garden kept as a pleasurable promenade, and in supply of flowers, fruits and vegetables."

"Well," says the Squire, "it is an enormous sum of money to spend on a garden, and remember I could not always depend on getting things when I wanted them. Last season in London I had to buy Mushrooms, Peas, and other things. I cannot be expected to spend this large sum of money on my garden and then have to purchase common vegetables."

In vain Brown protested that he could not grow Mushrooms without the aid of the Squire's horses which he took away with him when he went to town, and that Green Peas were neither profitable nor easy to produce in the middle of May. His argument was not acknowledged, at any rate as convincing, and he did not find the Squire very reasonable on the other part of the question. After a considerable amount of what that gentleman would call reasoning and which many of my readers are only too familiar with, he winds up by saying, "You must reduce the expenditure unless you wish to see me in the workhouse."

"Certainly I will, sir; I will reduce it to any reasonable sum you can name, but I cannot do it all myself, I must have your assistance. I cannot do as much with 15s. as I could with 20s. Reducing the labourers' wages, discharging some men, and selling some of the produce as you suggest will not do it unless you consent to give up something which at present costs a large sum to produce or keep in order. Shall it be a portion of the flower beds, which at present take some 30,000 plants annually, and half a dozen men to keep in trim? The place would be improved by sweeping away the greater portion of these gaudy patches, and replacing them with what I should call more of an English flower garden. Shall it be a partial substitution of foliage for flowering plants in the mansion or less trimly kept pleasure grounds?" But the Squire would have none of these things. He went away saying, he "could not reduce the expenditure 6d. without having his garden spoiled," and poor Brown was left to struggle on with a less number of men, more limited materials, and act as a sort of market gardener who sells his wares in the nearest towns for less money than they cost to produce.

Good seasons, as good as fine weather could make them, have returned, but unfortunately they were not accompanied by the expected good times, and consequently the screw has been put on again and again.

Poor Brown is still alive and plodding away, but he is getting terribly shaky. His nerves appear to be unstrung; and although he has been a good honest fellow all his life, never injuring anyone but himself, there is a sort of timidity in all his actions, such as an honest man never ought to exhibit, and which betoken a gradual breakdown of the nervous system. He still works wonders with the means at his disposal; making bricks without straw or even without clay would be child's play compared to the miracles he is expected to perform. But he is, and is likely to remain, in this predicament—he can neither satisfy himself nor anybody else.

QUERY.—Has anyone gained anything by the line of action I have indicated? And what is to happen after the next move or two in the same direction?—WM. TAYLOR.

GRAPES AT CULZEAN CASTLE, Ayrshire.

So much has lately appeared in the horticultural press regarding the Grapes that have been exhibited from this fine fruit-growing establishment, that perhaps a few particulars of their appearance at home, especially the wonderful weight of fruit annually produced, may interest many readers of the Journal. At the outset I may remark that Culzean Castle is the principal Ayrshire seat of the Marquis of Ailsa, and is distant some fifteen miles from the town of Ayr, and five from that of Maybole; the former celebrated as the birthplace of the poet Burns, and the latter famous for its boot and shoe manufactures. The castle—a most imposing pile of modern buildings—is built upon the edge of a precipitous rock overhanging the sea nearly 200 feet high, and considered one of the most picturesquely situated

mansions in the country. The gardens are situate about a quarter of a mile from the Castle, and contain within the walls some six acres of highly cultivated and productive fruit and kitchen gardens. A wall runs through the middle from east to west, upon the southern aspect of which the principal fruit and forcing houses are built, consequently all lean-to's. But to the Grapes.

ALNWICK SEEDLING.—Culzean has been called the home of this fine Grape, and I think it justly deserves the title, as it is here grown to a very high state of perfection. The photograph I send you may enable you to form a better idea of its grandeur than any description I could give. It is grown in a late vinery in company with Lady Downe's and Alicante. Its bad setting qualities of which we sometimes hear are here unknown, being found in this respect as free as a Hamburgh. As to its keeping qualities its behaviour is rather singular. The Vines in this house are at present carrying their third crop. The first season they began to shrivel about the end of

Fig. 82.—Alnwick Seedling.

September. The next season they kept fresh fully a month or six weeks longer, while this season they are at the present time (Dec. 1st) quite plump and fresh, so with increased age this variety may yet turn out a late Grape, which in the early spring months would be a great acquisition. I may state that the crop was a very heavy one, averaging from 2½ to 3 lbs. per foot of rod, some bunches being over 5 lbs. in weight, and the finish simply superb.

MADRESFIELD COURT.—Here this grand Grape is also exceptionally well done. It occupies an adjoining house to the Alnwick Seedling one. To give an idea of the enormous weight of fruit carried by this variety I may state that this season, just when beginning to colour, from three rods 12 feet long that were thought rather severely taxed five bunches were cut which weighed 20 lbs., three of which form part of the rather imperfect photograph I send.

FOSTER'S SEEDLING.—In the same house this is equally fine, having grand bunches 5 and 6 lbs. in weight. This is a great favourite here, keeping in good condition from July to November, its rich yellow colour, coupled with the peculiar bloom, characteristic of this variety when well grown, giving it a fine appearance. It is found a heavy cropper, and was here finishing 3 lbs. to the foot of rod in grand style. As is well known, Foster's Seedling and Madresfield Court are two

varieties much given to splitting. Here this evil is almost unknown, judicious ventilation, with a constant circulation of dry warm air during the ripening process, being found a sufficient preventive without resorting to the "gimlet" or restricting the supply of water to the roots. A seedling raised a few years ago by Mr. Murray was on its trial in this house. It is a late black Grape and appears a good cropper, forming nice compact bunches of good-sized berries covered with a very dense bloom. It is quite distinct from any existing kind, and if its trial proves satisfactory will no doubt speak for itself when brought before the public. The next house was filled with a fine even crop of highly finished Lady Downe's. At one end of this house were two rods of Alicante, which carried some of the finest bunches of this variety we ever saw. Many would run 6 and 7 lbs., and perfect models in shape.

Next in order is a Muscat house which, although largely planted with this variety, also contains Gros Colman, Black Hamburgh, Buckland Sweetwater, and Gros Guillaume, the two latter proving their liking for warm treatment by their superior finish, the Bucklands displaying a very high golden colour, while the dense bloom of the Barbarossa gave its large handsome bunches a magnificent appearance. A Black Hamburgh rod was carrying a remarkably heavy crop. The length of rod is but 12 feet, and it would have over 40 lbs. of fruit, many bunches being 4 and 5 lbs. in weight. The next house contains a mixed collection, embracing Foster's Seedling, Black Hamburgh, Madresfield Court, Raisin de Calabre, Mrs. Pince, Golden Queen, and Gros Colman, all displaying superior examples of their respective kinds. The much-derided Golden Queen is here seen in grand style, large bunches with a rich golden colour. It is a noble-looking Grape when well grown, and should be in every collection, being a robust grower, free bearer and setter, and of excellent flavour, and hangs a long time in good condition. Mrs. Pince was also very fine, having very large symmetrical bunches and highly coloured. A rod of Raisin de Calabre set off the middle of this house with five magnificent bunches ranging from 10 to 12 lbs. each. Their great size did not seem to affect their finish in the least, as they were large in berry and of a rich golden colour. Another Muscat house finishes this fine range of vineries with remarkable examples of this high-class variety, bunches 14 to 16 inches in length, and from 10 to 12 inches across the shoulders being quite common in this house, and the finish all that could be desired, being of a rich golden hue. The crop was also quite as heavy as any in the other houses, averaging quite 3 lbs. per foot.

Such is a brief description of a few of the most striking varieties of Grapes grown at Culzean. Other fruits are equally well grown, of which I may have something to say at some future date. If I have not trespassed too far upon your space I will conclude with a few cultural remarks which may not be out of place. As already mentioned, the vineries are lean-to's, and are all of equal build, 13½ feet high at back and front sashes 2 feet, length of rafter 18 feet, but is not cropped to the top, 3 or 4 feet being left clear of foliage for the admittance of light and air, width of border, including outside, 23 feet, and is well elevated, the bottom being on a level with the surrounding ground, the advantages of this plan being higher temperature and thorough drainage. The soil is a very light sandy loam, and could not produce such wonderful heavy crops without liberal feeding, which it undoubtedly receives, Mr. Murray being a firm believer in plenty of water and plenty of feeding. At all seasons the borders are perfectly hard and firm and matted to the surface with small fibry roots. Hung upon the back wall of each vinery are neatly framed tabulated cards containing an accurate account of the progress and general management of each house, such as quantity of water given and when applied, different kinds of manure and quantities given, number of bunches and average weight carried by each variety, &c. As to the quantity of water vigorous Vines in well-drained borders require the following may show. From the 1st of February to the 1st of September of this year the inside borders of six vineries received over 30,000 gallons, which does not include the water received from having the borders covered with bedding plants in spring and heavy dampings two and three times a day throughout the summer, besides many drenchings to the outside borders, and this quantity was deemed insufficient, but owing to the past dry summer curtailing the supply more could not be given. Of manures, many kinds have been used both natural and artificial. Of the latter prominence is given to that wonderful root-producing manure manufactured by Messrs. Thomson of Clovenfords. It is here largely used for many things besides Vines with the most satisfactory results. The Vines are planted 3 to 4 feet apart, according to variety, overcrowding being strictly guarded against, the aim being to allow each leaf as much light and air possible. Everything thoroughly clean, the most scrupulous attention to every detail in connection with their management, with plenty of hard work, are a few of the particulars accredited for the above-mentioned results.—B.

[The engravings are from photographs taken by our correspondent

and we have never seen any to surpass them, with some others before us, as the work of a gardener.]

ICE HEAPS.

I SEE at page 513, December 10th, of the Journal, mention made of an ice heap. When I went to Kilkerran House, Maybole, Ayrshire, on the 30th September, 1860, there was a heap of ice that had been made in December, 1859. Very little was used out of it in 1860, and it served us all 1861, and I never saw a finer lot of ice. The place selected for the stack was close to the stable yard, an open space amongst some large trees, gently sloping towards the north. The first thing done was to put a fence about 5 feet high, made of strong posts, and covered with slabs from the sawmills, all round. As far as I can remember the one under notice would be about 25 feet. We then paved the centre to within 2 feet of the fence, keeping the pavement a little higher than the surrounding ground. On this pavement we built the ice, making the edges with large pieces, and breaking what is put into the centre into small pieces. It was built straight up till as high as the fence, then the head was formed the same as a haystack, then filling the 2 feet between the fence and ice with wood sawdust, till the top of fence was reached; we then covered the head of the stack with Spruce branches, and over these about 2 feet of sawdust was placed, taking care always to keep it as white as possible on the top, so that the sun's rays will not penetrate it.—W. WILSON, *Kingsknowes, Galashiels.*

I THOUGHT the following note might be of use to some of your readers who have to do with the storing of ice. I have not had any experience in this branch of the gardener's duty myself, but my late father had in his time a fair amount. Some years ago he told me that he had just made an ice stack, but instead of breaking the ice in the usual way, he had it marked out in convenient sized slabs. Some men were then put to work with handsaws, sawing along the lines. The slabs were then got off the water, put into carts, and taken to the place of stacking, and piled one upon another. He said there was a saving of time and labour, and the ice kept well, also that it was not difficult to cut with a saw. The ice was a good thickness.—T. S.

SANDRINGHAM WHITE CELERY.

MR. MCINDOE at page 514 of your Journal describes the above Celery as his "Alpha and Omega." I can fully endorse what he has said in its favour, and will add that it is the best frost and wet-proof Celery I have ever tried. This being a moist and mild climate a few degrees of frost destroy most other kinds, so we depend upon Sandringham White for our general supply.

I think that White Plume will have but a short life. The thought of having good white crisp Celery without earthing was too good to be true.—W. O., *Fota, Cork.*

CHRYSANTHEMUMS AND THEIR CULTURE.

(Continued from page 545.)

BEST TIME FOR STRIKING THE CUTTINGS.

OPINIONS differ considerably as to when the cuttings ought to be struck. Some growers find one time the best, and some another. My experience is that there is no hard-and-fast line to follow in this matter, because it occasionally happens that cuttings of some varieties cannot be had when desired, so stubborn are the plants in producing them. As Chrysanthemums are grown for various purposes, and as all cultivators do not grow the plants for the same end, it will be better to state the best time to propagate for each system of cultivation. This I will endeavour to explain. Having made this phase in the cultivation of Chrysanthemums a special study, I am certain the times named are the best for the various purposes indicated; but, as above suggested, it is not absolutely necessary to carry out the work at the exact time mentioned in all cases.

In growing the plants for the production of cut blooms for exhibition, any time after about the 10th of December till, say, the same date in January is the best period for propagation; but when the cuttings can be had the former date is preferable, as more time is then allowed for steady growth in a cool temperature, and growths thus produced have the best possible chance of becoming solid through the proper maturation of the tissues of the plants. Some growers prefer to strike the cuttings in bottom heat in February and March, but plants treated in this manner are never so good for the production of such high-class blooms as are afforded by plants raised earlier, for the reason that time will not allow of their proper development during the various stages of growth. The wood of late-struck plants never ripens thoroughly, which is a decided disadvantage much felt by growers in the extreme north of England. Another objection to late propagation is the space required to preserve the old plants for the production of cuttings for two months longer than is necessary when early propagation is adopted, as the space required for the cuttings is obviously much less than is needed for accommodating the old plants, and at that

time of the year space is valuable. Nor can the cuttings be preserved in such a good state as they are two months earlier, as they are sure to become drawn and weakened, and in this condition they sustain a greater check in being severed from the parent plants; and checks in any form and at any time are certainly detrimental to the welfare of the plants.

Some growers strike Chrysanthemum cuttings in November. This I consider too soon, as plants raised so early are liable to give trouble in April and May by insisting on the production of bloom buds instead of growth shoots. This is a source of great annoyance—particularly to growers in the south of England. When the plants do this nothing short of cutting them down to near the soil will check their premature blooming, and often the growths made after this cutting down are useless through the same cause—a production of flowering instead of growth shoots. Some varieties are more liable to this than others, but the evil is mainly induced by the too early propagation of the plants. Growers in the north are not troubled nearly so much with this precocity as those in the south, because the seasons being earlier the plants grow so much faster during March and April than they do in the north; therefore it is wise for growers resident in the north to propagate as near the first-named date (December 10th) as possible, always commencing with the weakest-growing varieties (of which Lady

Fig. 83.—Foster's Seedling.

Hardinge and Criterion are examples), as these require a longer season of growth than the more robust kinds, of which Prince Alfred is an instance.

Some growers say that late propagation reduces the height of the plants. This is correct in some instances, but it is generally at the expense of the blooms. To insure these in the highest possible condition height is essential. I have not yet seen—save in quite an exceptional case or two, through some unaccountable reason—blooms of the same quality produced on dwarf plants as upon those grown in what I will term a more natural manner in regard to the relative heights attained under the two systems. Let it be clearly understood I am speaking in a general sense of those varieties which are naturally tall, and not those which are habitually dwarfer under any system of treatment; therefore I contend that to produce blooms of the highest class the plants must be treated somewhat in a natural way of growth.

For trained specimen plants of all shapes to attain a large size the early part of December is the best for propagation, as it is quite necessary that the plants have a long season of growth, which cannot be had by striking cuttings late. The production of prema-

pure buds above mentioned is somewhat prevented by the frequent pinching out of the points of the shoots, this being necessary to get them of the size and number required before they have grown sufficiently long to form flower buds.

Chrysanthemums intended for what is termed decorative or bush plants do not require to be struck so soon as those intended for large specimens or for exhibition blooms, medium or smaller plants being more useful for decoration, and for this purpose quantity of bloom is of more consequence than quality of the individual flowers; therefore any time during the end of January or early in February will be soon enough. Pompons being so well suited for the decorative system are also better struck at the same time, but where they are grown for the production of exhibition blooms or specimens the cuttings ought to be inserted at the end of December or very early in January.—E. MOLYNEUX.

(To be continued.)

HOT WATER v. SCALE.

I HAVE never had occasion to use hot water for destroying scale on my fruit trees in the open, but, with reference to "Inquirer's" letter in your last number, I may give the result of my experience with it as applied to Peach trees in unheated houses.

Some three years ago, on entering my present situation, I found the Peach trees very badly affected with brown scale. The means taken to rouse the enemy was syringing the trees several times with water heated to 140°, making sure that the water reached every portion of the trees. Immediately afterwards the scale was observed to have a shrivelled appearance, and gradually vanished. Judging from the exceptionally heavy crops of fruit the trees carried the following season it was evident they were not injured by the hot water. To make sure of keeping the trees clear I am repeating the hot-water treatment every winter. Besides syringing the trees as indicated shortly before the buds move in spring, they are syringed with cold water (soft if possible), to which petroleum is added in the proportion of half a wineglassful to each gallon of water. Petroleum and water of this strength need not be washed off the trees again, but the inexperienced should remember that the mixture must be kept well stirred during the whole time the syringing is going on. I do not claim having originated the hot-water cure, it being well known to many gardeners; but I may mention that my information with regard to the temperature of the water—140°—was derived from the *Gardener* ten or twelve years ago.—D. M.

NATIONAL ROSE SOCIETY.

THE National Rose Society held their annual general meeting on Thursday, the 17th inst., in the rooms of the Horticultural Club, Covent Garden Hotel, 1, Henrietta Street, W.C. There was a comparatively small attendance of members, partly owing to the circulars calling the meeting having been issued somewhat late, and partly also to the near approach to Christmas rendering it inconvenient for many to visit London. Letters were received from sixteen members regretting their inability to attend, but twenty-one members arrived before the proceedings were commenced, the following being the names of those present:—Rev. Alan Cheales, Reigate; Capt. Christy, Sidmouth; Frank Cant, Colchester; T. W. Girdlestone, Sunningdale; Wm. Rumsey, Waltham Cross; G. W. Piper, Uckfield; J. Burrell, Cambridge; Thos. Gravely, Horsham; John Sargent, Reigate; Alfred Slaughter, Steyning; H. Wallis, Brentwood; A. Turner, Slough; W. J. Jefferies, Cirencester; W. H. Williams, Salisbury; B. R. Cant, Colchester; George Paul, Cheshunt; E. B. Lindsell, Hitchin; Richard Bloxam, Eltham; George Bunyard, Maidstone; H. Appleby, Dorling; T. B. Haywood, Hon. Treasurer; and the Hon. Secs., the Rev. H. H. D'Ombraim, Ashford; and Mr. Edward Mawley, Great Berkhamstead.

The proceedings commenced shortly after 3 P.M., and in the absence of the President and Vice-Presidents Mr. Richard Bloxam was elected Chairman. The usual preliminary business was then executed. Mr. Mawley read the circular calling the meeting, the minutes of the last annual meeting were taken as read, and Messrs. G. Bunyard and A. Slaughter were appointed scrutineers of the ballot for the election of officers and Committee.

The Hon. Sec., Rev. H. H. D'Ombraim, then read the annual report, which follows:—

REPORT OF THE COMMITTEE FOR THE YEAR 1885.

The Committee of the National Rose Society have again the pleasure of congratulating their members upon a very successful year. Although this was in many localities by no means a favourable season for Roses, yet the Exhibition at South Kensington proved the largest the Society has yet held. Indeed, but for the hot weather which prevailed at the time, it is very doubtful whether the conservatory could have held all the exhibits which would have been sent in. The Exhibition at Manchester also, bearing in mind the continued drought, must be considered a very good one. It is encouraging to find how rapidly the culture of Roses is on the increase throughout the country, and how many new members are year by year being added to the list of exhibitors.

HYBRID TEAS.

Upon the recommendation of the Sub-committee it has been decided

that "so-called Hybrid Teas be in future classed and exhibited as Hybrid Perpetuals."

FINANCIAL STATEMENT.

This the Committee cannot but regard as very satisfactory, for notwithstanding that £67 12s. has been this year paid in defraying the remaining cost of the publication of the new illustrated Catalogue, there still remains a balance to the credit of the Society of £40 19s. 1d.

ARRANGEMENTS FOR 1886.

The Committee have made arrangements for the metropolitan Show being again held at South Kensington on Tuesday, July the 6th, and for their provincial Exhibition to be held at Birmingham on Thursday the 15th of the same month. The latter Exhibition will take place under the auspices of the Birmingham Botanical Society.

MEMBERS' PRIVILEGES.

Members subscribing £1 are entitled to two private view tickets, and also to four transferable tickets, admitting at the same time as the general public. Members subscribing 10s. are entitled to one private view ticket, and also two transferable tickets. Each one of these tickets will be available at either of the Society's Exhibitions. Those members who are subscribing for the first time in 1886 will each receive a copy of the Society's new illustrated Catalogue of exhibition and garden Roses.

While tendering their best thanks to those kind friends who have in various ways assisted to help forward the work of the Society, the Committee feel that they cannot pass over in silence the great loss which this Society has sustained through the death of its late Vice-President, Mr. George Baker of Reigate, who had always taken the warmest interest in the Society's welfare. In losing him, not only has the National Rose Society lost a valued officer, but many of its members will miss a kind and genial friend. To the local secretaries the thanks of the Committee are especially due, for it is mainly through their exertions that the Committee are able to announce that the number of members on the Society's books now, for the first time, exceeds 400. They also feel much indebted to the Committee of the Horticultural Club for allowing the meetings of the Society to take place in their rooms.

A few remarks followed as to the satisfactory character of the report, and upon the proposal of Mr. G. Paul, seconded by Mr. T. W. Girdlestone, it was resolved that the decision of the Committee, to the effect that "The So-called Hybrid Teas be in future classed and exhibited as Hybrid Perpetuals," be added to the report. The Hon. Treasurer, Mr. T. B. Haywood, then read the following financial statement for the year:—

NATIONAL ROSE SOCIETY BALANCE SHEET, YEAR ENDING 30TH NOVEMBER, 1885.

Audited and found correct.
F. TULLIE WOLLASTON } Auditors.
J. D. PAWLE }
Chairman, RICHARD BLOXAM.

(Signed)
T. BURT HAYWOOD, Hon. Treasurer.

Some formal business was next transacted, the adoption of the report and financial statement being proposed by the Chairman, seconded by Mr. T. W. Girdlestone, and carried unanimously, as was also a hearty vote of thanks to the Horticultural Club for the use of their rooms, the proposer and seconder being respectively Mr. Sargent and Mr. B. R. Cant. A similar recognition was accorded to the officers and members of the Committee for their services during the past year. It was then announced that the officers and members of the Committee proposed for 1886 had been duly elected, the following being the names of those selected.

List of Committee and officers for the year 1886:—President, the Rev. Canon Hole; Vice-Presidents, the Hon. and Rev. J. T. Boscawen, Rev. J. M. Fuller, Robert Hogg, LL.D., James McIntosh; Hon. Treasurer, Thomas Burt Haywood; Hon. Secretaries, Rev. H. Honeywood D'Ombraim, Edward Mawley; General Committee, H. Appleby, Rev. H. A. Berners, Rev. H. B. Biron, R. Bloxam, G. Bunyard, Rev. J. B. M. Camm, B. R. Cant, F. Cant, Rev. A. Cheales, Captain Christy, E. Claxton, J. Cranston, C. E. Cuthell, H. H. French, Rev. F. H. Gall, T. W. Girdlestone, W. J. Grant, T. B. Hall, J. Shirley Hibberd, The Rev. Canon Hodgson, C. F. Hore, J. House, W. J. Jefferies, E. B. Lindsell, Dr. M. T. Masters, F.R.S., Rev. F. Page-Roberts, G. Paul, F. C. Pawle, J. D. Pawle, Rev. J. H. Pemberton, G. W. Piper, G. Prince, W. Rumsey, J. Sargent, A. Slaughter,

A. Turner, E. R. Whitwell, E. Wilkins, Rev. W. Wilks, W. H. Williams; Hon. Auditors, J. D. Pawle and F. T. Wollaston.

A discussion took place respecting the locality of the provincial show in 1887, as it has been found necessary to make the requisite arrangements a considerable time in advance. Numerous towns were mentioned as suitable, several members naming towns in the west of England, such as Worcester, Gloucester, Cheltenham, and Bath, but it was generally decided that for various reasons these are undesirable, one of the principal reasons being that the districts named are rather too early, and another being that the western counties are well supplied by the annual Rose Show at Bath. Shrewsbury, Chester, Hull, and others were also named, but though no decision was arrived at, the majority appeared to be in favour of Nottingham if satisfactory terms could be arranged.

Another matter of much interest came under consideration—namely, the improvement of the medals offered by the Society, which it was said had given dissatisfaction to some recipients. It had been previously determined that some alteration was desirable, and Mr. T. W. Girdlestone was entrusted with the task of communicating with Mr. Pinches with a view to obtain a more artistic design, and at the same time increasing the value of the silver medals. Designs for both the gold and silver medals were now submitted, and gained general approval, being most artistically executed, and such as cannot fail to give satisfaction to all. It was proposed by Mr. G. Bunyard, and seconded by Mr. T. W. Girdlestone, that the new designs be adopted, and that the dies be prepared.

The lists of varieties admissible in the classes provided for new Roses were placed before the Committee, and it was decided that a clause should be inserted in the schedule to the effect that "new varieties first announced in English catalogues in 1884 or subsequently should be admitted."

The meeting concluded with a hearty vote of thanks to the Chairman, proposed by Mr. G. Paul, and seconded by Mr. Appleby. With a few exceptions the members present at the meeting remained to the dinner, which took place at 6 P.M.

FRUIT AND PLANT HOUSES.

(Continued from page 515.)

In the cultivation of fruit trees and plants of warmer climes artificial heat is important. It is essential that our climate be made equal by artificial means to that the plants enjoy in their native habitats. Upon the different modes of heating I shall not make any lengthened observations; suffice it to state that heating by flues or hot air is obsolete. It answered and still answers where parsimonious considerations are permitted to override those of efficiency and economy. Cheap first costs almost invariably bring dear after costs. The investment of a pound sterling should bring in a per-centage of interest, and will if a profit can be made of its employment; but if it be only half of what is needed to insure profit it must prove a loss in proportion to its inefficiency to insure the purpose intended. Nothing is so dear as poor fuel or an obsolete boiler. It is no use trying to get as much heat out of breeze as coke, or out of coke as coal. Breeze is the refuse of coke, and coke is the refuse of coal. Breeze is not much used, indeed it need not be taken into account as fuel, and wood is so little used that it may be left out. Cinders, the result of the ashpit after the smaller particles have been removed by sifting with a sieve having half-inch mesh, I find pay, especially as I use the sifted material for earth closets. The ashpit ought to be distinct from the dust or rubbish bin. I have two compartments—that for the ashes under cover, so that the work of shifting can be done in unfavourable weather for outdoor work, and the dusthole is exposed, and emptied weekly. The cinders from the house, containing as they do much small coal, are, I consider, quite equal to coke from the gasworks in heating power, and burn in any ordinary boiler furnace.

Gas coke, or the coke resulting from the manufacture of gas, is that mostly used in boiler furnaces, and it answers very well, especially in those that have considerable capacity for fuel, and are constructed upon the slow-combustion or self-feeding principle, so as to need attention at several hours' interval. The principle itself necessitates a large furnace, and a large furnace needs a large quantity of fuel of no very great heating power, or rather of slow ignition or combustion. If we take an ordinary boiler furnace we find it will only need one-fourth the coke to charge it as it would of coal, it being so much lighter and more open, so that whilst we use a quarter cwt. of coal we have only a quarter the bulk of coke of the like weight. We get out of the 28 lbs. of coal not much less heat than we do out of the 28 lbs. coke, with the difference that the coal does not act on nearly the same extent of surface through our system of stoking at distant intervals as the coke does, and in result we do not obtain anything like as much heat from the quarter cwt. of coal as from the quarter cwt. of coke. We get the same heat, but with the coal, owing to the large space in the furnace, it does not act on the surface wanted heated, and it passes off with the air entering to insure combustion by the smoke flue or chimney being cooled by the air entering the furnace but not passing through the fire, therefore not consumed, and if not con-

sumed it is only so much cold air mingling with the heated in the furnace and diminishing its heating power proportionately. Now this is the principle of all heating—viz., the heat concentration on the surface required to be heated, and the way to secure it is to proportion the size of the furnace to the fuel used rather than the surface wanted heated. If we use coal we want a smaller furnace than if we use coke, and we also must have the surface to be heated brought as near to it as possible—in fact into direct contact with it, or directly in the fire. This would point to the coil or pipes passing directly through the furnace or fire as the best system of abstracting heat, and I am not certain that it is not the difficulty being in its application. Direct contact I hold to be of primary importance, or if not that the full force of the products of combustion concentrated on the abstracting surface, for the greater the heat acting on a given surface the more heat we obtain, as the force is in proportion to the circulation, and *vice versa*. For instance, if we concentrate the heat of the furnace on 3 feet of surface instead of 6 feet we more than double the force of the heat and the circulation, consequently obtain more heat off the lesser surface than the larger. This gives a large boiler more power proportionately than a small one, inasmuch as we obtain a larger action of the fire, not really much greater in size in the large than small boiler, on a larger surface, and obtain more direct heat.

Of the forms of boiler that answer these conditions best we have first of all the saddle. It fits directly over—in fact, encompasses the fire—forming the three sides of the furnace, and is brought as near to the fire as is consistent with holding or affording space for sufficient fuel to last under slow combustion not less than eight hours. We have direct contact at the sides, and what heat escapes action there is concentrated on the crown of the boiler, and with a check end we still further obstruct the heat, and all obstructing surface means heat extraction. If we have hollow grate bars we have the fire resting on, surrounded by and obstructed in its passage outward by a surface containing water required to be heated. The saddle, therefore, is a heat-extracting useful boiler, which from its simplicity is not likely to get out of order, and suffers little depreciation through wear and tear.

The upright or conical form of boiler is also useful. The furnace is surrounded by heating surface, the fire must pass over a large surface even in the slow-combustion boiler, and be concentrated upon the crown before the heat makes its exit by the smoke-flue or chimney.

There are modifications of these forms of boiler, the chief object of which is to make the fire or heat pass through alongside and over the outer surface of the boiler, and I pass one verdict upon them—viz., the futility of seeking to utilise what has been wasted in the furnace. In the side flues we heat the bricks more than the boiler, and these passages are so often clogged with soot as to be practically useless.

We come to the blacksmith's mode of heating—thrust the boiler right into the fire or furnace. Instead of the boiler forming the outside of the furnace it is placed directly in it, so that the fire or heat acts upon all its surfaces, the surfaces forming the furnace having great heat-absorbing power, being formed of firebrick and fireclay, and as this is prevented striking laterally or vertically, being isolated from external influences by a cavity filled with sand, we get the greatest heating power. This we have in the tubular boilers, which differ only in having the tubes upright or horizontal. The upright was originated by Messrs. Weeks and the horizontal by Messrs. Messenger, and upon these there have been various innovations and improvements. For heating a large extent of piping the tubular boiler is pre-eminent, but for less than 1000 feet of 4-inch piping I do not consider them suitable; suffice it to state that by diminishing the size of boiler we do not get a surface at all equal to the size of furnace as we do in the larger boilers, and they are not economical, but for heating extents of piping over 1500 feet I consider the tubular unrivalled.

As to form, I have a decided preference for the upright boiler, as this form has more heating power, but it labours under the disadvantage of not being suitable for any or every kind of fuel, as to work it satisfactorily it requires coke. Horizontal tubulars having for the most part check-end waterways are very powerful, and have two advantages over the upright, in that they will burn any kind of fuel, and do not require a deep stokehole, which are very great advantages in places where coke is not readily procurable, and where the water naturally is near the surface and drainage difficult.

For heating 1500 feet of 4-inch piping or less I consider the saddle form of boiler most suitable; whether we have the Cornish Trentham boiler with waterway terminal end, the Terminal End Saddle and Flue, or even Cruciform Saddle or Gold Medal, the principle is the same—viz., bringing the heating surface as near to the heat as possible, and so that it will be concentrated upon it with the greatest force.

The heating power of a boiler is contingent upon the surface exposed to the direct action of the fire and upon the water it contains. If we take a tube an inch in diameter we get four times the heat surface for the same quantity of water as if we employ a 2-inch tube; therefore heat four times the quantity of water, for as is the heat so is the circulation, or it will circulate very much more quickly in the small tubes than in the large. I make no account of indirect heat, only in that the heat is utilised in maintaining or preventing the loss of the direct. It is best utilised in heating, as in the Cornish Trentham, by passing under the boiler, and so warming the cold water before it is acted upon by the direct heat of the furnace. In the hollow grate bars of the Terminal Saddle as well as in the Tubular boilers the water is heated before it is acted upon by the full force of the furnace heat, but the heat in this case is direct, and it must be said greatly auxiliary. Except, therefore, in utilising indirect heat, preventing the loss of direct heat, or in warming surfaces wanted heated which are colder than those exposed to the greatest heat, its benefit is purely chimerical.

Boilers are economical not only in construction but in the way the heat is utilised after it is obtained. The water should have free access in entering the boiler and an equally free passage out, but it must be understood that as soon as it leaves the boiler it is losing heat, and continues to do so throughout the whole extent of the pipes. Some have an idea that a main of large diameter is necessary. Now, just get a 2-inch pipe and give it a sharp incline, and it will carry off as much water as a pipe of double the diameter on nearly a dead level. This of course is due to gravity, and in heating by hot water we have not only gravity but the ascending force of heat. What reason is there to take a 6-inch or 4-inch main from the boiler to the house required heated when the water will travel much more quickly through a 2-inch, and we have only an eighth of the water, with half the extent of radiating or heat-losing surface? These mains, whatever their size, are taken in flues and are bare, therefore losing heat the whole of their length, whereas were they covered with hard felt they would radiate or lose very little; and when we take into consideration the loss occasioned by the needless large flow and return pipes, their exposure throughout the distance between the source of heat and the structure required heating to cooling influence, we have to face a waste of power of a most extravagant kind, which is added to by an oversight in valves to shut off the heat alike from the house and boiler. How often do we see the valves on the pipes just inside the house, leaving it may be half as much piping between the house and boiler without means of disconnection? The water will not rise up the flow, still less the return pipe—i.e., it cannot circulate. Why, it circulates in a kettle, and it circulates in pipes, even in the return pipes after disconnection at the house up to the points of disconnection from the boiler, and this is all waste heat. If the mains pass through houses required heated, then of course these remarks lose their point, but in the case of detached houses they are worthy of consideration from an economical point of view, and the point of disconnection ought to be at or near the boiler. I once had under my charge half a dozen detached houses heated from one boiler, and to have taken the heated water to them in full-sized or 4-inch mains would have required as much surface in connection as the houses required heating surface. More money is wasted in "cobbling" by unskilled hands than is necessary to execute anything in the best manner of the best material. I had a box made, and from this all the flows were taken, and all were 1½ inch, and the valve upon each close to the box. Similar means were taken with the return pipes just before entering the boiler. It answered perfectly. The cold water had free access and the hot free passage out of the boiler. All the pipes ought to have valves—screw valves on the flows and throttle valves on return. If they are worth anything at all the screws will shut off to a drop, and the throttle will effectually check or close the circulation. Hot water will back up the return pipes, hence the need of valves on them.

The next chief point is to have plenty of piping, and as a rule small houses require more piping proportionately than large ones do, and lean-to's require less piping than span-roofs. Then houses required to be kept at a high temperature will bear the water or heating surface hotter than those which need only a temperate heat, as the latter are more susceptible of heat than the former. About half as much heating surface is required for a greenhouse as for a stove, and as a rule for calculating the heating surface needed I think there is none better than allowing a 4-inch flow and return for every 6 feet of width for securing a stove temperature for forced Grapes, Figs, Cucumbers, Melons, &c., whilst half that will suffice for a greenhouse. Height, of course, has much to do with it, but taking the height to be not more than the width squared, I find it answer very well, and is better than making no end of calculation about feet of heating surface required to heat so many cubic feet of air the chief thing being to have too much rather than too

little. Any extra first cost will be more than counterbalanced by the saving in fuel and the results obtained.

As to the best position for the pipes I do not think we can improve upon having them at the front of lean-to's or at the side of spans, being careful only to have them isolated, clear of the walls above the soil, and so that the atmosphere will not be so dried as to seriously affect the plants. If the pipes can be placed so as to diffuse the heat equally all the better, but I have tried it and find that the best results are obtained when they are at the lowest part of the house, and only in the case of wide houses are back pipes in the case of lean-to's, or centre pipes in the case of spans, needed; but in large houses they are wanted, so as to keep up a circulation of air throughout with an equality of moisture, but then the centre or back piping should not be more than one-half that of the front or side.—G. ABBEY.

(To be continued.)

WE understand that a HORTICULTURAL CONGRESS AT PARIS will be held in conjunction with the French National Horticultural Society's Show on May 4th to 9th, 1886.

— IT is announced that THE ROSARIAN'S YEAR BOOK FOR 1886 will be issued shortly, and will contain a photograph of Mr. B. R. Cant, together with the following articles:—"A Symposium of Mildew" (illustrated), "Winning Roses," "The Fortunate Isles and their Roses," "The Rose, and National Rose Society in 1885," "Some Single Roses as Decorative Plants," "Dew of the Ever-living Rose" (a review), "Climbing Roses," and "The Rose Weather of 1885."

— THE ROYAL BOTANICAL SOCIETY OF MANCHESTER have fixed the following dates for their Shows in 1886—Spring Show, 16th and 17th March, and 27th April; National Horticultural Exhibition, 11th June and following days; Rose Show, 17th July; Chrysanthemum Show, 23rd and 24th November.

— "T. S." writes:—"On reading the remarks of our friend "Thinker" on GAS TAR I was reminded of a case which was related to me some time since, and which goes to show that it will spoil the flavour of less delicate productions than Peaches. Gas tar was used in the Potato store to drive away rats, and all the tubers placed in the vicinity of the tar were strongly flavoured with it."

— WE regret to announce the death of MR. ALEXANDER PROTHEROE OF LEYTONSTONE, which took place on the 19th inst., in the eighty-second year of his age. Mr. Protheroe was one of the founders, as he was the head, of the firm of Protheroe & Morris, the well-known auctioneers and nurserymen of Leytonstone.

— WE understand that the post of ASSISTANT DIRECTOR OF THE ROYAL GARDENS, KEW, has been offered to Mr. D. Morris, M.A., F.G.S., the Director of Public Gardens and Plantations, Jamaica. The appointment is in the gift of the First Lord of the Treasury.

— THE annual general meeting of the KINGSTON CHRYSANTHEMUM SOCIETY was held on the 16th inst. in the Wood Street Schools, Mr. Lyne of Wimbledon taking the chair. The balance-sheet was read by the Hon. Secretary, Mr. T. Jackson, and from this it appeared that the total balance at the beginning of the year was £105 2s. 9d. The subscriptions amounted to £110 6s. 6d., and the takings at the Show to £92 10s. 6d.; these with other minor items and the balance brought forward gave a total fund of £323 5s. 3d. The disbursements, including prizes, came to £212 5s. 9d., thus leaving a balance of £110 19s. 6d. The receipts for the year exceeded the expenditure by £5 16s. 9d., which, considering they had two bad days for the Show, Mr. Jackson considered was exceedingly satisfactory. The other business transacted by the re-election of Mr. F. A. Davis as President, Mr. Drewett as Hon. Treasurer, Mr. T. Jackson as Hon. Secretary, and the Committee as follows:—Messrs. Attrill, Bates, Child, King, Lyne, Moorman, Orchard, Puttock, Rolt, Shepherd, Slade, and Woodgate, the new members being Dr. Walker and Mr. Glover.

— IN his article on BOUVARDIAS on page 537 last week Mr. A. Pettigrew meant to say that some of the plants produced corymbs almost as large as "Lilacs," not as "Lilies."

— THE CRYSTAL PALACE HORTICULTURAL SHOWS to be held in 1886 are fixed for the following dates:—Spring Exhibition of Plants and Flowers, March 26th and 27th; Great Summer Exhibition, May 21st and 22nd; Grand Exhibition of Roses, July 3rd; Fruit Exhibition and National Dahlia Show, September 3rd and 4th; Great Autumn Fruit Show and Grand Chrysanthemum Exhibition, November 5th and 6th. Schedules will be ready early in January on application. The date of the Potato Show is not yet fixed.

— MESSRS. THOS. CHRISTY & Co. request us to mention that the fire on the premises they occupy at No. 6, George Yard, Aldgate, on the night of the 12th, has not caused any interruption to their business, as all orders are being supplied from their warehouse at No. 2, George Yard.

— MESSRS. J. LAING & Co., Forest Hill, send us a coloured plate of "ROYAL TUBEROUS BEGONIAS," which represent some of the latest improvements amongst these useful plants. All the flowers are of great size, the centre one (Queen Victoria) being $7\frac{1}{4}$ inches by $6\frac{1}{2}$ inches. They are also distinguished by the broad rounded petals and their brilliant colours. The varieties portrayed are as follows:—Queen Victoria, rich scarlet; Prince of Wales, dark scarlet; Princess Victoria, white edged with deep rose, very pretty; Prince Albert Victor, orange scarlet with a white centre; Duke of Edinburgh, maroon striped, one of the darkest yet obtained; Princess Louise, pure white; and Duchess of Edinburgh, orange tinged with red on the edge.

— IN Mr. Major's collection of curios at Cromwell House, Croydon, STAPELIA GIGANTEA has been flowering during the last fortnight. The flowers are of great size, measuring 5 inches across from the points of the segments. These, however, recurve much the same as in *Lilium lancifolium*. The flowers of the Stapelia are deep purplish brown, are covered with silvery hairs half an inch long. The appearance is very remarkable, and this species is so rarely seen as to render it noteworthy.

— WE have received a letter addressed to Mr. F. C. BARKER, who contributed a note on Chrysanthemums a fortnight ago. This letter shall be forwarded if our correspondent sends us his full postal address.

— WE are informed that Mr. R. P. PERCIVAL of SOUTHPORT died on the 14th inst. of congestion of the lungs at fifty years of age. Mr. Percival has become well known in the horticultural world as an experienced amateur cultivator of Orchids, and at his residence, The Cleavelands, Birkdale, Southport, he had one of the best collections in the north of England. Cattleyas form an especial feature, and when describing the garden on page 52 of our issue for July 17th, 1884, we gave an illustration of a handsome specimen of *C. Sanderiana*, which had eighteen flowers, each 9 inches in diameter. Mr. Percival's name is commemorated in *Cattleya Percivaliana*, now included in most large collections of Orchids.

— PARTICULARS of a SALE of VALUABLE ORCHIDS in NEW YORK are given by the December number of "Vick's Monthly Magazine" as follows:—The Orchids were the property of the late Mrs. M. J. Morgan, Madison Square, and the collection originally cost about £40,000. In addition to the American nurserymen present there were agents representing the principal English firms, the following being the largest prices realised. A plant of *Vanda Sanderiana* was bought for £180, one of *Cypripedium Morganianum* for £150; *C. Stonei platyneurum* brought £90, and other *Cypripediums* realised various sums from £20 upwards. A specimen of *Vanda Lowi* was sold for £80, and *V. Batemani* for £20. *Cattleya exoniensis* sold for £50, £48, and £26, *C. labiata* for £20, and *C. Skinneri* for £40. This is one of the most important sales that has been held in America.

— A DINNER to commemorate the first PORTSMOUTH CHRYSANTHEMUM SHOW was held last week in the Royal Albany Hotel, Portsmouth. The chair was occupied by Mr. F. Power, T.C., the popular Secretary, the vice-chair by Mr. G. Ellis; and amongst those present were the Mayor (A. S. Blake, Esq.), Alderman W. D. King, J.P., J. Moody, Esq. (ex-Mayor), including most of the Town Council of the Borough and principal tradesmen of Portsmouth and Southsea. The usual loyal toasts were proposed, and in the course of several speeches which followed, Mr. F. Power stated that it was intended to offer a Challenge Cup value £25 next year for thirty-five cut blooms. Mr. E.

Molyneux, in proposing "The Exhibitors," remarked that he would like to see amateurs and cottagers compete more freely than at present, and he thought with suitable encouragement they would do so.

— WE have received the following books, which we shall notice in due course:—"Animal Life on the Farm," by Professor Brown; "The Golden Gate and Silver Steps," by Shirley Hibberd; "The Praise of Gardens," by Albert F. Sieveking; "The Practical Poultry Keeper," by L. Wright.

— GARDENING APPOINTMENTS.—The following have been made through Messrs. John Laing & Co., Forest Hill Nurseries, S.E.:—Mr. John Lawrie, as head gardener to Colonel Haworth Booth, J.P., D.L., Hull Bank House, near Hull; and Mr. A. McLeod, as head gardener to C. Stead, Esq., Nottingham Hall, Kent.

— WE have received from the "South" Publishing Company Fleet Street, specimens of ORANGES GROWN IN FLORIDA, which have just been received from Jacksonville *via* New York. The great impetus that has of late years been given to the cultivation of the Orange in Florida makes this importation specially interesting, as showing what we may expect from this new field. It is not that the cultivation of the Orange in Florida is at all new that the interest attaches to it, but that the development of it has of late years been taken up with so much energy, and as an investment of capital it has proved highly remunerative. The condition of the fruit showed that it had been gathered before it was ripe, and that the circuitous route by New York did not add to the ripening of it. If, however, the fruit was allowed to ripen in the same degree as that grown in St. Michael's or Valencia, and shipped direct from Jacksonville or some other port in the South, so that it would arrive in the same condition as fruit from these parts, there can be no doubt that a large trade might be done.

— MR. W. BARDNEY observes, "The bright scarlet ZONAL PELARGONIUM JOHN GIBBONS is superior to any we have for flowering during the winter in a temperature of 50°. We grow about 1000 plants for winter flowering, and this is without doubt the most showy and profuse of all. It makes trusses of a large size, which for brilliancy of colour are unsurpassed; and all who do not grow this variety should obtain it. For a long time we thought *Vesuvius* superior to any other as a profuse and continuous-flowering variety in the temperature named, but even this valuable variety is insignificant by the side of John Gibbons. It may be stated that cut-back plants, or those two or more years old, flower more profusely than young plants raised from cuttings in spring. Young plants might, if the season was not good, prove disappointing. I have grown all the new white-flowered varieties that have been sent out since *White Vesuvius*, but none of them can be compared with that variety for profuse flowering. The flowers are neither so well shaped nor pure in colour as *Eureka* and others, but it produces a mass of flowers in the temperature named, which the others will not do, in fact we are discarding all other white varieties for winter flowering."

— THE Liverpool Horticultural Association this year offered their certificate and first prize for an essay on THE CULTIVATION OF THE CHRYSANTHEMUM, the conditions being, that all competitors must be under-gardeners and members of the Society, and that the essay should take about twenty minutes to read. The winner of this prize is Mr. John Breen, Spital Hall Gardens, Cheshire, who on Saturday evening last, at the Association's usual meeting place, Free Library, William Brown Street, Liverpool, read before a large attendance of members his paper, which was a clear, intelligent, and detailed account of how to proceed with the culture, the wants, the enemies, of "Liverpool's favourite flower." The essayist briefly described its management from the cutting, the various potting operations, and the suitable times and composts for each, staking, feeding, housing, and other important items for the production of exhibition blooms and plants. An animated discussion followed, in which Messrs. T. White, A. R. Cox, W. Tunnington, R. G. Waterman, and others took part. The various opinions given by noted prizewinners as to temperature for striking, suitable soils and manures, and selecting the buds, proved that the Chrysanthemum can be grown under circumstances and modes of treatment differing to a great extent, but yet with satisfactory results. The arrangement of exhibition cut blooms, and the judging of the same, were also criticised in a friendly spirit, and added to the instruction of those present. Mr. A. R. Cox exhibited a box of cut blooms, which were exceedingly good for so late in the season. The varieties were—Boule d'Or, very fine; Meg Merrilees, F. A. Davis, Fabian de Mediana, Mabel Ward, and Princess Teck.

MR. W. T. THISELTON DYER, C.M.G., F.R.S.

A FEW weeks ago we published a portrait and sketch of the life of Sir Joseph Dalton Hooker, the retiring Director of the Royal Gardens, Kew, and we now introduce to our readers Sir Joseph's successor, Mr. W. T. Thiselton Dyer, whose name is well known in the annals of botany and horticulture. It was generally expected that Mr. Dyer would have been called to occupy this important position. His devotion to science, and especially natural science, his notable antecedents, and his ten years' probationary work as Assistant Director of the gardens, eminently fitted and recommended him for the appointment. The directorship of Kew is a post that requires of the holder a special training. It is one which no mere botanist, any more than no mere gardener, is capable of filling satisfactorily, but it requires a judicious combination of the two. These qualities are well met in Mr. Dyer, who, though eminently a man of science, has also a broad practical side which can be turned at any time in the direction where it is required. He knows that science without practice is dead, and that it is only when applied that it is really living.

Mr. Dyer was born on the 28th of July, 1843, in Westminster, with which his family formerly held some official connection, but his early life was spent in Mayfair, where his father practised as a physician. In his youth he suffered from indifferent health, and in consequence made long visits to the house at Edmonton (then a rural village) of his maternal grandfather, Thomas Firminger, LL.D., a man of considerable scientific attainments, who had been for fourteen years Principal Assistant at the Greenwich Observatory when Dr. Maskelyne was Astronomer Royal, and he was an intimate friend of Sir James South and other scientific men of that time. His mother was an ardent collector of British plants, and it is to her that he owes the formation of his botanical tastes, and we have heard Mr. Dyer say that one of his earliest recollections is trying to identify with her from Sir William Hooker's admirable "British Flora" the species of *Chenopodium* and *Atriplex*, which abound in Middlesex. His uncle, the Rev. T. A. Firminger, long resident in India, was the author of a well-known manual of gardening for India, which has run into three editions. All the associations of his youth were therefore with mathematics and botany; and his father being a member and for some years Chairman of the Apothecaries' Society, it was his habit to carry home for him specimens of medicinal plants which were sent for the weekly examinations from the Chelsea Botanic Garden. This circumstance no doubt laid the foundation of the peculiar interest which Mr. Dyer has for pharmaceutical botany.

Mr. Dyer's early education was acquired at King's College School, and it was at that time that the beginning was made of introducing science teaching into the school course. Lectures on Chemistry and Physics were given by Mr. Charles Tomlinson, F.R.S., and he has still a keen recollection of the pleasure and interest he derived from them.

During the latter part of his school life he bestowed most attention on mathematical studies, and left with the first-class mathematical scholarship in 1861, the present Astronomer Royal being at the time somewhat his junior in the school. Here, too, he contracted a friendship with Dr. Trimen, now the worthy successor of Dr. Thwaites as director of the Royal Botanic Garden, Peradeniza, Ceylon, through the discovery in those school days of their common interest in botanical tastes.

On leaving school Mr. Dyer was undecided whether to go to Cambridge or commence medical studies. Ultimately choosing the latter, he entered the medical department of King's College in 1861 as Warneford scholar, and attended with great enthusiasm the lectures of Lionel Beale, who then stood in the front rank of the revived school of minute anatomy in England. He, we believe, was one of the first teachers who attempted to demonstrate, with an ingenious form of travelling microscope, the actual facts of histology to his class. All this is done now with admirable effect in the laboratory, but Lionel Beale's attempts were, in their way, a revolution in teaching. William Allen Miller was then fully occupied with the new spectrum analysis, and freely introduced the new subject into his course; and to the clear and systematic teaching of his old friend Professor Bentley he owes his first accurate technical knowledge of botany.

In 1863, his health having given way, by his father's advice he abandoned any farther attempt at studying for the medical profession. In the autumn of this year a Junior Studentship at Christ Church, Oxford, was offered for open competition, which he had the good fortune to obtain, a success he owed in great measure to his medical scientific instruction, and also to the diligent study of the late Dr. Carpenter's "Comparative Physiology," which is now generally recognised as having led the way for the modern methods of biological teaching.

At Oxford Mr. Dyer resumed mathematical study, but he had lost ground too much to be able to accomplish the whole course of University reading, and he was quite content to take a second class in moderations in 1865, and a second class in the final Mathematical School in 1867. The teaching of Professor Henry Smith in modern geometry, and of Sir Benjamin Brodie in modern chemistry, are features in his university life which he can always look back to with the keenest pleasure. After taking his B.A. degree in 1867, he obtained a First Class in the School of Physical Science, and then left the university.

Shortly afterwards his father died rather suddenly, and he was thrown very much on his own resources. His first appointment was that of Professor of Natural History in the Agricultural College of Cirencester, and here his residence for two years among the Cotswold Hills was in every way of great benefit to him. Elected a member of the Cotswold Club he joined in excursions over a country which displays every geological formation from the Lower Tertiary to the Upper Silurian, and this enabled him to see an epitome of the world's history which is perhaps not to be found elsewhere. To his friend Mr. Church, who was then

Professor of Chemistry at the College, and is now occupying a similar position in the Royal Academy, Mr. Dyer owes in no small degree an insight into the chemistry of vegetable nutrition. With the help of an old Kew man he had charge of a small botanic garden with an excellent collection of British plants. During his stay at Cirencester in 1869, Sir Joseph (then Dr.) Hooker, though knowing little of him personally at that time, offered him the Directorship of the Royal Botanic Garden of the Mauritius, on the death of Dr. Mellor, in Australia; but on account of the delicate state of his health he regretfully declined it. In this year he edited, with his friend Professor Church, the English edition of "How Crops Grow," and published with Dr. Trimen the "Flora of Middlesex," for which they had been steadily collecting material since their school days.

In 1870 Mr. Dyer became Professor of Botany in the Royal College of Science for Ireland in succession to Dr. Wyville Thomson. Mr. Dyer says, "I owe a great deal to my residence in Dublin, especially to my friend Mr. William Archer, F.R.S., Secretary of the Dublin Microscopical Club, and now Librarian of the National Library of Ireland. He introduced me to the fascinating microscopical Fauna and Flora of the Irish bogs. But, above all, I must ever commemorate the memory of Dr. David Moore, of the Royal Botanic Garden, Glasnevin, near which I took up my abode. He allowed me free access to all its treasures, and a larger experience only makes me to more fully appreciate the skill to which difficulties of cultivation seemed to have no meaning."

Part of his official duties in Dublin was to deliver a short course of popular lectures. Reports of these appeared in some of the Irish papers, and were reprinted in the columns of the *Gardeners' Chronicle*. This circumstance brought him to the notice of the Council of the Royal Horticultural Society, from whom he received an invitation to join the staff as Professor of Botany, with a seat on the Chiswick Board of Direction. This offer was accepted, and he returned to London in 1871. At the same time he was asked by Dr. Hooker to assist him in the "Flora of British India," and he worked up the *Dipterocarpeæ* and a few minor orders contained in the first volume. Soon after this the affairs of the Royal Horticultural Society became involved by the partisanship of rival interests in the Society. The purely horticultural element of which it was composed found that a strong party existed, consisting chiefly of the residents in the neighbourhood of South Kensington Garden, who were desirous of converting the Society to their own uses, and instead of maintaining it as a society for the advancement of horticulture, they endeavoured to alter its character, and succeeded for a time in expelling the old Council and appropriating it as a place of amusement and recreation. In consequence of this the Society became disorganised, and changes were made which for a time reduced the administration to the level of a committee of management of a London square; in this catastrophe Mr. Dyer was, of course, unable to fulfil all the hopes with which he entered on his work at South Kensington. "But," says Mr. Dyer, "I certainly owe much to my periodical visits to Chiswick, and I saw under the skilful management of Mr. Barron the side of horticulture which supplemented what I had seen at Glasnevin. The meetings of the Chiswick Board brought me into intimate relationship with the Rev. M. J. Berkeley, Dr. Hogg, and Mr. Moore, and in such company it was an advantage to be inexperienced."

In 1873 Mr. Dyer was invited by the Science and Art Department under which he had worked at Dublin to conduct a course of instruction to teachers in what is now the Normal School of Science at South Kensington. In this he was assisted by his friend Mr. Lawson, the late Professor of Botany at Oxford, and now director of the Cinchona plantations of the Madras Government. They had the use of Professor Huxley's convenient and well-appointed laboratory, and here they entered upon a course of instruction which embraced the leading morphological facts of every important type in the vegetable kingdom; in fact, they resolved to adopt exactly the same plan of work as Professor Huxley in his own teaching had found convenient for the animal side of morphology. This we believe was the first time that any attempt had been made in this country to give an extended course of botanical instruction of this kind. This was an experiment which was repeated at regular intervals during the next few years. It gradually took a more systematic shape, and first at the hands of Mr. Bower, now Regius Professor of Botany in the University of Glasgow, and then by Dr. Scott, it is likely to settle down to a permanent system of instruction.

In 1875 the Government revived the office of Assistant Director of the Royal Gardens, and Mr. Dyer was offered the appointment. Having taken up his residence at Kew two years previously, he had opportunities of becoming acquainted with the work of the establishment, and he accepted the offer, though with some misgiving, as it seemed to close the door finally to a teaching career, which he then had most at heart. What the schools may have lost in this resolution of Mr. Dyer the public service has gained, for we know of no one who could have more efficiently administered the department during the time he held the post of Assistant Director than he has done. We now look forward with confident expectation to the future, feeling assured that Her Majesty's Government have made an appointment which will tend to sustain the reputation of the Gardens justly acquired under the masterly direction of the two Hookers—father and son—and now confided to the son-in-law of the latter.

Mr. Dyer is a Fellow of the Royal Society, and in consideration of his admirable management of the Colonial Department of the Kew establishment, Her Majesty conferred upon him the distinction of Companion of the Most Distinguished Order of St. Michael and St. George.

SOME account of the great establishment placed under Mr. Dyer's

direction will be appropriate now, and we therefore give a review of its history as published in the Official Guide-book.

"About the middle of the seventeenth century the spot that now forms the Royal Gardens of Kew, together with a residence called Kew House, belonged to R. Bennett, Esq., whose daughter and heiress married Lord Capel. Kew House and Grounds then passed into the hands of Mr. Molyneux, who was secretary to King George II. when Prince of Wales, and who married Lady Elizabeth Capel. The Prince of Wales, who was son to George II. and father to George III., admiring the situation of Kew House, took a long lease of it from the Capel family about the year 1730, and began to form the pleasure grounds, then containing about

and of Mr. Allan Cunningham to Australia; the expeditions of Bowie and Masson respectively to Brazil and the Cape of Good Hope—all these enriched the gardens of Kew with the vegetable productions of the southern hemisphere to an extent unparalleled before; besides which, other collectors were employed during a long period in various countries, and the produce of their researches was deposited at Kew. On various occasions, especially during the life of King George III., many houses, stoves, and pits were erected; but on the demise of that monarch and of Sir Joseph Banks, who died shortly after the King, the establishment suffered from want of Royal and scientific encouragement. During the reigns of George IV. and William IV. the hotanic gardens retrograded,

Fig. 84.—MR. W. T. THISELTON DYER, C.M.G., F.R.S.

270 acres. They were completed by his widow, Augusta, Princess Dowager of Wales, who delighted in superintending the improvements, then conducted upon a most extensive scale. The exotic department of this garden was commenced by the same Princess and much favoured by the Earl of Bute, about the middle of the eighteenth century. Many of the finest foreign trees were contributed by Archibald, Duke of Argyle (styled by Horace Walpole the Tree-monger), who sent them from his once richly stored garden at Whitton, near Hounslow.

"About the year 1789 His Majesty George III. purchased Kew House, and Queen Charlotte evinced much interest in the increase of the collection of plants. Under such auspices, and aided by the enlightened patronage of Sir Joseph Banks, it was only to be expected that the gardens of Kew should become celebrated all over the world.

"The voyage of Capt. Cook and Sir Joseph Banks round the world; those of Capt. Flinders and Mr. Robert Brown (Botanicorum Princeps),

and matters must have been much worse but for the able exertions of Mr. Aiton, and of his foreman (the late Curator), Mr. John Smith, A.L.S. Throughout the country an opinion existed, which soon began to be loudly expressed, that either the gardens should be entirely abolished or placed upon a very different footing, and rendered available as a great popular yet scientific establishment for the advantage of the public.

"Government was, happily, ready to respond to this latter feeling, and in 1838 the Lords of Her Majesty's Treasury appointed a committee to inquire into the management, condition, &c., of the Royal Botanic Gardens. The result was in May, 1840, a return was made to the House of Commons in the shape of a report by Dr. Lindley, who, at the desire of the Committee, had surveyed the gardens in conjunction with two well-known practical gardeners.

"Many useful suggestions offered by Dr. Lindley were acted upon, especially the following:—A national garden ought to be the centre

round which all minor establishments of the same nature should be arranged; they should be all under the control of the chief of that garden, acting in concert with him, and through him with one another, reporting constantly their proceedings, explaining their wants, receiving their supplies, and aiding the mother country in everything that is useful in the vegetable kingdom. Medicine, commerce, agriculture, horticulture, and many valuable branches of manufacture would derive much benefit from the adoption of such a system. From a garden of this kind Government would be able to obtain authentic and official information on points connected with the founding of new colonies. It would afford the plants there required without its being necessary as now to apply to the officers of private establishments for advice and assistance.

"The limit of the garden not being exactly defined where it met the precincts of the residence of the King of Hanover, permission was obtained to include within the botanic garden all the ground immediately about the conservatory and orangery, which greatly enhanced the beauty of the view and added between three and four acres. Soon after application was made to the Queen for a grant of land from the contiguous pleasure ground, which might afford the means of forming a pinetum (or a collection of plants of the Pine tribe) and of erecting a Palm stove or tropical house worthy of the place and the nation. Her Majesty was graciously pleased to permit a portion of the pleasure ground, comprising about forty-seven acres and including a piece of water, to be devoted to these purposes, and enclosed within a light wire fence, which now separates the botanic gardens from the pleasure ground.

"Again, in the winter of 1846-7 orders were received for abolishing the Royal kitchen and forcing gardens of Kew as such, and incorporating them with the botanic garden, thus adding fifteen more acres to the scientific portion of the grounds (seventy-five acres in all)."

The gardens themselves are now so well known that it is unnecessary to refer to them in detail, for during the last ten years they have been visited by some millions of people, the total on some holidays rising to 50,000 and 60,000 in one day. This popularity, considered in conjunction with the scientific and what may be termed the commercial work performed in the establishment, is evident proof that the efforts of those in charge to render it of national interest and importance are fully appreciated. There has for some time been a broadening of the system upon which the gardens are managed, and in regard to the culture of the large collections the advance has been great. In an establishment open to the public there are necessarily many difficulties to contend with, especially in the cultivation of the indoor plants; but it has long been reasonably thought that there was no substantial reason why, with the appliances and labour at command, the plants should not be as well grown as in private gardens. In recent years considerable efforts have been made to effect this, in which the Director and Assistant Director have been ably assisted by the Curator, Mr. John Smith, and a competent staff. The result is seen now in the generally satisfactory condition of the collections, and certainly never in the history of the gardens have the plants been more healthy.

The extension of the collection has also received careful attention, and by exchange or purchase, large numbers have been added in the past few years. A well-judged liberality in sending the foremen of the principal departments on tours to the leading botanic gardens and nurseries, both at home and on the Continent, has similarly resulted in important additions, which have increased the scientific interest of the gardens. Not the least of the matters that have received the earnest consideration of the authorities has been the improvement of the young student gardeners, and every facility has been afforded them of gaining knowledge by means of numerous courses of lectures and an excellent library.

FERNS—THEIR HISTORY AND HABITATS.

[A Paper read before the Paxton Society by Mr. J. G. Newsham of Sheffield.]

POSSESSING myself a strong desire to become fully acquainted with the habits, peculiarities, and the natural abode of Ferns, it has also always been a source of pleasure to reveal to others that which I have gleaned. I propose to give in a brief form the result of my observations bearing upon the various strata and soils which are most productive of Ferns. At the same time, I shall endeavour to convey the observations made by others, who, from their more extended travels and perhaps closer investigation, have a higher claim to authority upon the subject.

It may not be generally known that Ferns claim precedence in the history of this earth over other plants which adorn our greenhouses and stoves, except the Pines and Palms. They are the oldest inhabitants of the earth, the first productions of the rocks upon which we live. To man we are not indebted for their history, but to the rocks themselves. They give us indisputable proof of the existence of Ferns long before man existed to cultivate or even to admire them. I may be pardoned, I think, if I digress a little by referring to their geological history.

I shall therefore carry you back to that period in the pre-adamic ages, which most geologists term the fourth day's work of the Mosaic account of the creation. This period has undoubtedly been the great Fern era. Writers tell us that the earth at that time was thickly mantled with Ferns, Pines, and Palms, and from the present existing evidences there can be no doubt that it was a period of luxuriance in foliage, which all

lovers of Ferns might well wish to have beheld. It was a period of a warm moist atmosphere, a period upon which only a very moderated light was shed upon the earth. The soil, if soil it could be called, was simply composed of sandy gritty substances, which through the action of the waters had been lodged in crevices and fissures of rocks, or washed into the valleys. No wonder, then, that with all these advantages Ferns flourished. And that they did flourish, and for a long period too, is abundantly proved by the productions of the various strata which have been from time to time revealed.

Those who have given their attention, casually or otherwise, to this pleasant study of the time when the earth was undergoing the many various changes to which it has been subjected in order to complete it for man's abode must have been struck with amazement at the rapid and continual growth of vegetation which is supposed to have eventually formed our present coal measures. Immediately above the coal seams we find innumerable specimens of Fern fossils. Many of them are very conspicuously imprinted upon the hard-pressed gritty substances, which through lapse of time have been converted into a kind of slaty coal. To Fern lovers this is a notable page in the great book of Nature. Dr. Buckland beheld in the coal mines of Prague "festoons of graceful foliage flung in wild profusion over every part of the walls of the mines; scaly stems and bending branches, with their delicate foliage were spread out in coal black hues on the light ground of the hardened lime muds. The vegetable forms of extinct trees, thus preserved in beauteous profusion, have become the faithful historians of times long gone by, their delicate leaves and fine fronds laid out as distinctly as a botanist could spread out his treasured plants on a sheet of paper." Although we consider our present Ferns beautiful and delicate in form, yet they will not bear comparison with the Ferns of the pre-adamic ages. The Tree Ferns of New Zealand, Brazil, Norfolk Island, and other parts are the only representatives of the gorgeous fronds and tall trunks of the ancient Fern period. There is little doubt that myriads of Ferns grew then the like of which we do not now possess. It may be, perhaps, of some interest to you to observe what rocks were then most productive of Ferns, and the comparison they bear with the rocks of our present time. In the primary rocks not a vestige of vegetable life can be traced, owing no doubt to the want of moisture at that time. Neither do we find at the present time that granite and mica slate produce any speciality. Upon these formations we find but few plants which appear to be natives of these strata, and upon which I shall remark shortly. We find in the recesses of earth various Ferns of the common order growing profusely in these districts, but they are mainly those Ferns which owe their existence to the accumulations of rich vegetable soil.

In the transition rocks we do find traces of extinct Ferns. The yellow sandstone, and red sandstone, and grey fossil sandstone all contain evidences of vegetable life. Visit our sandstone districts at the present time and you will find luxurious growth, especially upon the old red sandstone. It is upon this formation that our stoutest *Polystichums* and most robust *Athyriums* are found. Take, for example, Heath's Fern Paradise, Devonshire. Perhaps in no other county do we find its equal. Admitting the fact that the climate may have a great influence upon this southern extremity of the British Isles over other sandstone districts, still it testifies to the rich production of the strata under favourable circumstances. In fact, I may almost affirm that by far the greater portion of our Ferns of tall and vigorous growth at the present time are the inhabitants of those districts which abound in sandstone.

In the mountain limestone we have three layers or beds. It is the topmost layer in the coal measures that we find such a large variety of fossil Ferns. These are mainly Ferns of less vigorous growth, but although unassuming in their dimensions and of humbler habit, they were infinitely superior in texture, design, and variety. The Ferns we find upon our calcareous districts take very much after those found buried in the mountain limestone, except in variety. Small, yet neat and finely designed, they are more ornamental than their brethren of the sandstone ranges.

The secondary rocks, those known as the Wealden group, furnish us with the remains of Ferns of gigantic dimensions, Ferns which inhabited the then marshy lands and swamps, Ferns which must have assumed the proportions of trees of great height; a very large number of Palms, which for size would not be credited at the present time were it not for the remains which have been discovered and which speak for themselves. Our *Osmunda* is but a mite compared with its forefathers. Our present male and female Marsh Ferns are very poor representatives of these early inhabitants of boggy lands. A very consider-

able amount of decayed vegetable matter (no doubt the remains of ages of Ferns which grew and died away in quick succession) must have existed to support the massive roots of these primeval giants. Still, if we compare our present productions of bogs and marshes with our existing varieties of higher birth or elevation, the comparison is certainly in striking contrast with those of their progenitors.

I will now refer to the modern history of Ferns—that is, such as we are able to relate, for I can assure you that until very recently, say the last century, the information to be obtained has been very limited. The ancient Greeks make reference to Ferns, and, I believe, are the first writers who notice them, and then only as medicinal herbs. The only distinction which was then noticed, or which was believed by them really to exist, was the “Male and Female” Fern. Whether the *Filix-mas* and *Filix-femina* of our authors were the two referred to by these ancient writers I cannot positively say, but I have no doubt that we owe our present popular names to those worthies.

It was not until the latter part of the sixteenth century that Ferns began to attract special notice. At all events, some attempt at classification was made, and although the discovery of their organs of production was not made manifest until the end of the eighteenth century (which discovery has since then given rise to a correct adjustment of their various classes), yet to these early authors, Ray, Gerard, Parker, Lyte, and others we owe the first not unsuccessful attempt to remove the confusion which surrounded them.

The first seedlings of which we have any record were raised in the year 1789 by Lindsay of Jamaica and by Fox of Norwich. This is rather a singular coincidence, that about the same period though in countries so far distant two persons should have succeeded in making the discovery, and of inaugurating the ultimate success in the art of propagation. I should occupy too much time by entering into a detailed statement of the history of each of our separate species. It will be quite sufficient to remark that the popularity to which graceful plants has reached during the present century is ample evidence of their deserving merits. You find them everywhere—in every conservatory, in every aquarium, in refreshment rooms, in workshops, adorning the halls and entrances to public buildings, places of amusement, and, last but not least, lending a charm to tasteful designs and casements of the cottager’s window.

(To be continued.)

JUDGING FRUIT.

THERE are, as has been already observed, two or three points in connection with this subject which are fairly open to discussion. 1st, Should all Apples or Pears be ripe when exhibited? When ripeness is not specified is it desirable, that judges in Pear and Apple classes should make it a prominent point in giving their decisions? Grapes, Peaches, Melons, and all fruits which attain their highest state of perfection only when allowed to remain on the tree or plant till ripe should, for obvious reasons, be perfectly ripe when placed on the exhibition table; but in respect to Pears, Apples, and all similar fruits which do not, as a rule, ripen on the tree, “ripeness” should not, unless specified in the schedule, be made an element in judging them, otherwise our autumn exhibitions of these special fruits would soon become poor indeed from the exclusion of the later and most valuable varieties, while probably the inferior kinds would gain all the prizes, because exhibitions cannot be conveniently held at a later period of the year, and shows would thus lose considerable interest, because many valuable varieties would scarcely ever appear on the exhibition table at all.

In respect to uniformity in collections of Pears and Apples I would approve and by all means obtain as much uniformity as possible in the fruits which compose each separate dish, but I would carry the rule no further, lest by so doing collections should be injured by excluding the choicest because possibly the smallest varieties. I would rather judge each dish on its own merits, having special regard for fine examples of the choicest varieties, whether small or large kinds, instead of looking for uniformity over the whole collection.

Some objections have been raised as to the propriety of committees granting extra, or, it may be, consolation prizes when, in their opinion, the judges have not given correct decisions. It would assuredly prove injurious and probably destructive to horticultural shows if such a course was frequently or erroneously adopted; but granted a mistake has been made, and judges, like other men, are but fallible, hence the mistakes which do sometimes, though happily not often, occur, not only by judges in horticulture, but also in agriculture and also by judges of men. This being so, would it be right or even wise to allow the error to remain unrectified, and so permit the worthy to go unrewarded or the innocent to suffer? or would it be just and more wise to endeavour to make amends to the meritorious or the innocent? If so, by whom? Which is the proper court of appeal? and who the fittest arbitrators? The judges themselves cannot with propriety reverse their own decisions, nor would it conduce to the generally good and kindly feeling which happily exists amongst gardeners if others were engaged then and there to condemn or

confirm the awards, and to postpone or refer the decisions to a future tribunal as in Courts of law, would, for obvious reasons, be unfair and impracticable. Under these circumstances I cannot help thinking that the fittest arbitrators are those gentlemen who form the committee. They can at once, without allowing time to change the circumstances, adopt such means as will in their opinion best rectify the error.

Moreover, are not the judges paid for their services by the committee, and so, for the time being, are they not virtually the servants of the committee? He, being master, is not the committee morally and legally justified in correcting any mistakes which, in its opinion, have been committed by its servants? and what is equally certain and most desirable is that the committee can best do this with the least possible degree of irritation to all parties concerned. Discretion and discrimination are most essential qualities in such cases, and fortunately the gentlemen who form horticultural committees may fairly claim their proportionate share of them.—T. CHALLIS.

NEW ORCHIDS OF 1885.

SOME reference was made last week to the number of Orchids certificated this year, and it might be reasonably expected that amongst so many there would be a good proportion of beautiful novelties. This is the case, but, at the same time, owing to the number of improved varieties of older types shown, there are not many of what might be termed startling distinctness. We cannot expect such surprises as *Vanda Sanderiana* every year, for the native haunts of Orchids both in temperate and tropical regions have been so thoroughly explored that it is only by a lucky chance collectors now discover a species exceptionally distinct from those in cultivation. No doubt Professor Reichenbach could tell us of many grand Orchids that have yet to be introduced, but the principal efforts of importers now seem to be to obtain shiploads of particular species that are in much demand. This process has been carried on for several years, and will have the effect of exterminating some forms in their home countries, and when the supply becomes exhausted the prices here will rise proportionately, as has already been experienced in several cases. There is, however, another matter to be considered, and that is the awakening of some of the native Governments to the value of the enormous quantities of plants annually taken from their shores, and the result is that some have imposed a heavy tax on all Orchids shipped from their ports. This will, if generally practised, undoubtedly have a greater deterring effect upon the wholesale importers than anything else. Of course we must fully recognise the enterprise of firms who employ so many collectors and invest such large sums in the speculation; but the question is whether they do not gain a temporary benefit at the cost of a permanent injury to themselves and the trade generally.

There is one mode of increasing the diversity of Orchids which does not appear likely to be carried to an undue extent, and that is the raising of hybrids and fine varieties of well-known species. It is therefore satisfactory to notice the increased attention being paid to the subject. Nearly all the largest and most beautiful genera have yielded crosses, though a few, as the *Odontoglossums*, still prove too much for the skill of hybridists, and others, as the *Masdevallias*, have as yet given but poor returns in that respect. The genus *Cypripedium* has been the most prolific. The *Dendrobium*, *Cattleya*, *Lælia*, *Aerides*, *Calanthe*, *Phaius*, and *Zygopetalum* have all afforded some examples of artificial crossing; while of the *Phalenopsis* and *Odontoglossum* forms have been introduced that may be safely regarded as probable natural hybrids. It is strange that in such a large and varied genus as the *Oncidium* no crosses should have been obtained, though it might be supposed that there is a good field for experiment. Several handsome hybrids have been brought into public notice this year, and to these a few words may now be devoted.

Hybrid Calanthes.—Three charming *Calanthes* have been honoured with certificates this year, and all are hybrids, an important addition to the six previously obtained. Two of these novelties—*C. Alexanderi* and *C. Cooksoni*—were shown by their raiser, Norman C. Cookson, Esq., Wylam-on-Tyne, who has also secured several other crosses in the same genus. *C. Alexanderi* is the result of a cross between *C. Veitchi* and *C. vestita rubro-oculata*, and is chiefly remarkable for the pleasing contrast presented by the two lower white sepals with rich crimson colour of the other portion of the flower, the plant resembling *C. Veitchi* in its vigorous habit of growth and flowering. *C. Cooksoni* is of similar parentage, but *C. vestita luteo-oculata* was employed instead of *rubro-oculata*, with the result that a hybrid was secured with large pure white flowers, having a slight yellow centre and resembling *C. Veitchi* in the characters previously mentioned. Both are beautiful Orchids, and growers would gladly welcome more of the same type.

In the Burford Lodge collection Sir Trevor Lawrence has tried several experiments with *Calanthes*, and has succeeded in raising several improved forms, but much the best of these that have yet been shown is *C. porphyrea*, which resulted from a cross between *Limatodes labrosa* and *Calanthe vestita rubro-oculata*, a similar origin to that of *C. Sandhurstiana*, except that *L. rosea* was employed in this case. *C. porphyrea* is, however, quite distinct from the latter, the flowers more resembling the *Limatodes* in form, of a fine rosy crimson hue, the lip slightly cupped and spurred, lighter in the centre, and dotted with dark crimson. It is a beautiful Orchid, and though the flowers are not large, the brilliant colour amply compensates for any deficiency in that respect. It may be worth mentioning that the other hybrid *Calanthes* previously raised are as follows—*C. Dominii*, from *C. Masuca* and *C. furcata*; *C. Veitchi*, from *C. vestita* and *Limatodes rosea*; *C. bella*, from *C. Turneri* and *C. Veitchi*; *C. lentiginosa*, from *Limatodes labrosa* and *C. Veitchi*; *C. Sandhurstiana*,

from *Limatodes rosea* and *C. vestita rubro-oculata*; and *C. Sedeni*, from *C. Veitchi* and *C. vestita*.

Miscellaneous Hybrids.—Only two hybrid *Cypripediums* have been added to the list, and both are from Messrs. Veitch's establishment. *C. macropterum* is from *C. Lowi* and *C. superbians*, and is evidently quite intermediate in character. It is pretty, but cannot rank amongst the best of hybrid *Lady's Slippers*. *C. Sedeni candidibulum* is a beautiful form obtained by crossing *C. longifolium* and *C. Schlumi album*. It has been not inappropriately termed a "White *Sedeni*," and with the exception of the pale rosy lip the flower is pure white. Since it partakes of the free-growing and profuse-flowering habit of *C. Sedeni* it will take a place amongst the most useful members of the genus.

Dendrobium endocharis has been referred to before, but it deserves a further note, as it is unquestionably an Orchid that will find much favour with cultivators. It was raised from seed obtained by crossing *D. japonicum* and *D. heterocarpum*, and bears dense clusters of creamy white fragrant flowers, the lip being relieved by a blotch of crimson in the centre. In habit it resembles *D. heterocarpum*, and like that is a profuse flowerer. These easily grown *Denbros* are thoroughly useful plants, and the flowers of most of them are very durable, no mean recommendation in these days of large floral demands.

One of the most remarkable and handsome Orchids of the year is *Lælia bella*, for a plant of which Baron Schröder was awarded a certificate at one of the meetings of the Royal Horticultural Society. This superb hybrid is one of Messrs. Veitch's productions, having been raised from a cross between *Cattleya labiata* and *Lælia purpurata*, and partakes of both parents' characters in a remarkable manner. The flowers on the plants shown were over 7 inches in diameter across the petals, which, with the sepals, are pale rosy purple; the lip is 4 inches long, over 2 broad, and unequalled in the intense richness of its crimson hue. It is a magnificent Orchid, and is considered one of the most valuable at present in cultivation.

An interesting addition has been made to the comparatively small number of *Thunias* in the hybrid *T. Veitchiana*, which has been shown and certificated both at Kensington and Regent's Park this season. At the former exhibition it was shown by Messrs. Veitch and Mr. B. S. Williams, who had it under the name of *T. Wrigleyana*. As it is evident there has been some confusion in the naming, it will be well to give Mr. Williams's explanation of the matter. He says, "This plant, which has for some time been known to us under the name of *T. Wrigleyana*, was, we believe, first raised and flowered by the late Mr. G. Toll of Manchester, who named it after E. G. Wrigley, Esq., and subsequently sold us the stock. Since then it has been exhibited by Messrs. Veitch and Sons under the name of *T. Veitchiana* at the same time as exhibited by us under the name of *T. Wrigleyana* at the Royal Botanical Society's Show in 1885." Upon the label accompanying the plant shown by Messrs. Veitch it was stated that the seeds obtained from a cross between *T. Marshalli* and *T. Bensoniæ* were sown in April, 1881. It appears that flowers were subsequently submitted to Reichenbach, who gave it the name now accepted. We have therefore reliable evidence indicating that the same cross was effected with precisely the same results in two widely separate gardens. Apart from this interesting matter it is unquestionably a charming Orchid, the sepals and petals being white, the lip veined with purplish lilac or mauve and tinged with yellow, and is both free in growth and flowering.—L. CASTLE.

BERRY-PRODUCING PLANTS.

SUMMER and autumn are truly enjoyable times in the garden and there seems to be no reason whatever why a ramble should be not only pleasurable, but highly interesting also during the dull months of winter. In many gardens we see trees and shrubs grouped with great care and forethought for the beautiful autumnal effects of their foliage, which at the best lasts only a few weeks, and the same idea carried out with berry-producing shrubs, and evergreen or ornamental-foliaged plants, would last the entire winter and help to bridge over a season that in the majority of gardens is anything but pleasant. Considerable taste would no doubt be required to make the venture prove an attraction, but the plants at command seem to be so varied and at the same time so suitable to each other, that little difficulty will be experienced on that score. The number of plants that produce berries or brightly coloured fruits in this country is considerable were they all collected together. Fifty years ago an old writer said that "the hedgerows in winter are my gardens, loaded with the haws and haws, intertwined with the feathery tresses of the Traveller's Joy, here and there fresh bits of Ivy peeping out." What can be more beautiful in the open air just now than the common Spindle Tree, *Euonymus europæus*? Yet in 80 per cent of modern gardens it is a stranger. It is leafless truly, but the bare branches are covered with those curious brilliant-coloured fruits that catch the eye at long distances, giving a most pleasing effect, which is heightened by dull surroundings. A group of such plants, or in clumps of half a dozen judiciously mixed in shrubberies lighten it wonderfully. The common wild Rose, which during summer is so handsome studded with its pretty pink flowers, is none the less so now, the large richly coloured fruits being very desirable whether in clumps or other-

wise. *Hippophae rhamnoides* is also very useful at this season. Many of the varieties of Holly produce berries freely as well as the Hawthorns, a few of the American varieties being very handsome; *Cotoneaster Simonsii*, &c., many of which will occur to the reader, the above being merely an indication of the numbers that exist and fruit throughout mild winters. Among smaller plants may be mentioned *Vaccinium macrocarpum*, *Gaultheria procumbens*, *Hemiphragma heterophylla*, &c., unequalled for edging clumps and beds. Then there are many plants indoors that may be allowed to fruit for winter decoration; for instance, *Passiflora cærulea* trained along the roof or in festoons from pillar to pillar, loaded with its pretty egg-shaped fruits, is a grand sight. It also does well in the open air, but flowers too late to mature fruit. *Skimmia japonica* and its varieties are old favourites often cultivated in pots for decorative plants for corridors, &c., *Myrtus myrsinoides* is also worth growing, and *Microcachrys tetragona*, a drooping Conifer-like plant, with branches like a Cassiope and smothered with small bright red Raspberry-like fruits.—M.

SUMMER BEDDING PLANTS.

IF we knew beforehand what sort of weather we were to experience during the following summer we should be in a position to place out such plants as would be certain to give satisfaction, but as it happens we have to prepare as much as possible for any contingency. What we have to determine, then, is which are most suitable for all weathers, and to plant these principally in preference to those that may be classed as doubtful. In spite of numerous and noteworthy additions to our lists of summer bedding plants, Zonal Pelargoniums are still in the ascendant, and are likely to remain so I suppose as long as the fashion of summer bedding-out lasts. For my part I am heartily sick of "scarlet Geraniums," and I am not the only one by a good many who have had enough of them. We are under orders to rely principally upon them; they must preponderate in every arrangement, and nearly every bed in fact, as many as five hundred plants frequently be worked into the majority of our largest beds. It is true they are the most effective, glaringly so unfortunately, more especially during a hot and dry season, but they look very miserable indeed during wet weather, especially in sheltered positions, where the flowers are more flimsy. However, my object in penning this paper is not the condemnation of the bedding-out system, as that, I suppose, would be of no avail, but rather with the motive of pointing out which kinds of plants have proved the most generally useful here for some time past, though I could not resist having another grumble.

The most useful scarlet Zonal Pelargonium for all weathers is *Triomphe de Stella*, an old sort belonging to the Nosegay section, and of which Mr. Taylor grew many thousands when at Longleat. It is one of the best "tempered" sorts in cultivation, striking freely, and quickly becoming established in the beds, no matter how roughly it may have been used. In hot weather it is literally a blaze of scarlet, and it quickly recovers from the damaging effects of rain. The old Indian Yellow is of somewhat similar neat-growing, profuse-flowering habit; and this again is one of the best summer bedders. *Master Christine* is a good light pink, and Mrs. Turner is another rather vigorous-growing deep pink. *Henry Jacoby* is a great favourite with all who have it, no other variety producing finer trusses, and freely too, of colour rich crimson. In our rather sheltered garden strange to say we could hardly distinguish it from *C. Smith* and *General Outram*, but in more exposed positions the trusses of *Henry Jacoby* are the larger of the two. *West Brighton Gem* is a failure, being of weakly constitution, but *Fire Ball* is a good scarlet, and will be grown in preference to *Vesuvius*. Of bronze Zonals I prefer *Marshall McMahon*, and *Black Douglas* is also very showy, and these are wonderfully effective in all weathers. The same may be said of the yellow-leaved *Crystal Palace Gem*; while of the silver variegated sorts we prefer *Flower of Spring*, *Mrs. Mappin*, and *Bijon*, the latter for the centres of beds and for mixing with *Violas*. *Robert Fish* with greenish yellow leaves is useful for outside lines. Several sorts newer than the foregoing have been tried and found wanting. Numbers of them have better trusses of well-formed flowers, but after all are not so reliable as we expect them to be. The double-flowering sorts are serviceable only for hot and rather dry positions.

Verbenas are now seldom seen in quantity, but they are very brilliant when well grown. *Purple King* is still the best, while *Crimson King* and *Snowflake*, also old sorts, are as reliable as any. It is useless to attempt their culture unless a start can be made with clean healthy cuttings, as these only make plants fit to put out. Seedling *Verbenas* are suitable for large mixed beds, and these will grow strongly without any extra preparations, whereas those raised from cuttings require well-prepared and manured ground, as well as a summer mulching. *Verbena venosa*, propagated either from seed, or better still by root cuttings, succeeds admirably in some gardens, and is most effective when mixed with either *Veronica Andersonii variegata*, *Abutilons Thompsoni*, and *Darwini tessellatum*, white and yellow *Marguerites*, and *Pelargonium Bijon*, these being surrounded with a broad band of *Iresine Herbstii*, or *Iresine Lindenii* edged with *Golden Pyrethrum*, *Robert Fish Pelargonium*, or some dwarf silver-foliaged plant. Such a bed proves effective in all weathers, lasting well into the autumn.

Marguerites ought to be generally popular, but have not made so much progress as was at one time thought probable. They are easily

wintered, a few strong old plants yielding abundance of cuttings, which strike freely in heat, or they may be struck in the autumn and wintered similarly to Zonal Pelargoniums. They ought not to be planted in very rich soil or they grow too strongly, small plants soon becoming tall and bushy. In a sunny or rather dry position in mixture with single Petunias they succeed admirably. They are also effective when planted either in lines, in mixed groups, or as a groundwork for thinly planted beds of Ricinuses. For window boxes they are invaluable, immense quantities being annually used in London. When required for this purpose they ought to be raised in the autumn and stopped once or twice, and every shoot resulting will flower well in the spring. Etoile d'Or is a good yellow sort, and of the whites I prefer coronarium frutescens. For hot dry banks, or flower beds and borders that are naturally poor and dry, there are no plants to equal seedling single Petunias. On rich soil they are apt to grow too strongly, and do not flower nearly so freely as they do on poor soil. A packet of seed sown early in February will yield a great number of plants, which soon attain a good size. I have no faith in the very dwarf sorts sent out of recent years.

Lobelias are also easily raised from seed, and several of the strains can be depended upon for neatness of growth, freedom of flowering, and colour. We prefer to raise our stock either from cuttings or by division of a number of old plants wintered in a cool house or pit. These soon make good plants and form close bright lines of colour. *L. pumila magnifica* and *Brighton* are our favourite blue varieties, and *pumila Ingrami* is a good white. Ageratums on the whole are much more serviceable than Lobelias, neither very dry nor very wet weather appearing to greatly injure them. They are easily reared from seed, but for edging purposes plants raised from cuttings are the best. Cannell's Dwarf is perhaps the most dwarf of all, and would be invaluable for carpet beds if it was fixed in character. Many of the plants are apt to grow much too strongly and do not flower well, while those that retain their character produce nothing but bloom, and the stock is easily lost. Swanley Blue is our favourite, and may be said to be one of the most easily increased and most effective dwarf bedding plants in cultivation.

Pyrethrum Golden Feather flowers too readily, and does not stand wet weather so well as we should like, and for the future the preference will be given to *Pyrethrum aureum selaginoides*. The latter, though not so bright in colour, does not run to seed, and is much the best for carpet beds, not requiring so much plucking. *Centaureas argentea plumosa*, *gymnocarpa*, and *ragusina compacta* can all be easily raised from seed, and if sown early in the year the plants will be of good size at bedding-out time. They stand all weathers, and are very effective white-foliaged plants. *Chamaepeuces diacantha* and *Casabona*, the former silvery white and the latter green-foliaged, are very attractive dwarf Thistle-like plants, and suitable for dotting among dwarf carpeting plants. These may be raised from seed either in the autumn or in the spring. Of hardy Grasses for bedding purposes the best dwarf kinds are *Festuca glauca* and *Dactylis glomerata elegantissima*, the former being the most generally useful. They divide readily, and a large stock can thus be easily raised without the aid of glass. *Arundo donax variegata* grows to about 3 feet in height, and in mixed beds or a strong clump in the centre of a bed is most effective.

Fuchsia Golden Fleece is useful for bedding purposes, while *Chrysanthemum Sensation* and another old silvery variegated plant, *Polemonium caeruleum variegatum*, are still deservedly popular in some districts. *Coprosma Baueriana variegata* is also very handsome, but it is not extensively grown, being rather slow of propagation. The same remarks apply to the beautifully variegated *Veronica Andersoni variegata*. *Stachys lanata*, being perfectly hardy and free-growing, is not much prized, but we find it very serviceable as well as effective, and use it freely for edging large beds, dividing the old plants at bedding-out time only. The Golden Thyme loses its colour, otherwise it would be largely grown. *Euonymus radicans variegatus* is a very useful edging plant, and quite hardy. It takes some time to get up a good stock, but when this is accomplished the plants can be kept neatly trimmed into any shape. Cuttings will strike in handlights during the summer, and in heat in the spring. *Mesembryanthemum cordifolium variegatum* ought to be renamed, as it is much too long. It is a pretty edging plant, is also suitable for carpet beds, and forms the best groundwork for beds thinly planted with tuberous-rooted Begonias. *Koniga maritima* grows freely in all weathers, a little too strongly in fact, but it is very easily increased by cuttings in the spring, and is a very effective silvery variegated edging plant. *Iresine Lindeni* does not always thrive on heavy soils, but *Iresine Herbsta* succeeds nearly everywhere. *Alternanthera magnifica*, *paronychoides major aurea*, *arvensis spectabilis*, and *versicolor grandis* are all worthy of culture and are most effective in carpet beds.

I ought not, perhaps, to omit mentioning a few more flowering plants, and wish particularly to strongly recommend tuberous-rooted Begonias for summer bedding—not, however, the produce of any inferior strain, but rather the best sorts suitable for the purpose. Those that are most valued for pot culture we also find the best for the beds. Messrs. Laing and other well-known seedsmen supply seeds of capital strains of bedding Begonias, and if the plants are given fairly rich soil as well as mulched before hot weather arrives, they will flower grandly, almost rivaling the Zonal Pelargoniums for brilliance of colour, and certainly far surpassing them in wet sunless weather. Antirrhinums are very effective in beds, standing drought surprisingly, as also do Pentstemons. Heliotropes are general favourites, and a bed or beds of Miss Nightingale please everybody. The above list is by no means complete, but perhaps the omissions may be made good by some other correspondent.—W. I.

CANKER IN APPLE TREES.

I HAVE read Mr. Hiam's remarks on the canker in Apple trees. I quite agree with him in all he says. He forgets when he says I had not seen the insects, I said I had, and also my gardener, by the aid of a Coddington lens. I have no doubt in the matter, none. But I did not write on the question this time, for I deemed it useless. I suppose I am the "individual" that "Thinker" alludes to. He might in courtesy have mentioned my name as Mr. Hiam did. I do not like to be simply styled an "individual" in the controversy. I found that two Apple trees coated with Gishurst compound four times a year lost their canker and grew well, while that standing close by still continued to canker. All were in deep good yellow loam. I do not intend to go into the argument any further. I can but say, as regards canker, I discovered it was caused by insects, not from Mr. Hiam, but I most cordially agree with him in every way. I am perfectly satisfied myself, and shall not continue further, and should not have written now, only to correct what Mr. Hiam stated as to my not having seen the insects. Some Apple trees are more attacked by them than others. With regard to the trees being out of health, this was not the case, as they were in good soil, well drained, and were growing vigorously.—HARRISON WEIR, F.R.H.S., 34, Lansdowne Road, Tunbridge Wells.

NOTTINGHAMSHIRE HORTICULTURAL AND BOTANICAL SOCIETY.

THE third annual dinner of the members of the above Society was held in the large dining-room of the Nottingham Arboretum on Thursday last, December 17th, when a large company of members and their friends assembled. Various parts of the room were well furnished with a variety of choice flowering and ornamental foliage plants, whilst stands of choice cut flowers and fruits graced the tables, very noticeable being a nicely arranged stand of cut Orchid flowers, representing many varieties, sent by S. Thacker, Esq., one of the Vice-Presidents, and a noble Queen Pine from Chatsworth. The company consisted of many local magnates, in addition to a large number of gardeners, most of the gardens of the great houses of Notts being represented, as well as a number of local nursery firms. The Mayor (Alderman W. Lambert), President of the Society, occupied the chair, and was supported amongst others by the Town Clerk (S. G. Johnson, Esq.), F. W. Cooper, Esq., F. G. Baldwin, Esq., Alfred Page, Esq., J. P. Fearfield, Esq., H. M. Baines, Esq., A. J. Field, Esq., F. S. Granger, Esq., W. Sibley, Esq.; Messrs. A. H. Pearson and C. E. Pearson (Chilwell), Owen Thomas (Chatsworth), T. Macdonald (Messrs. Barron & Son), C. J. Mee (Wollaton Hall), J. Swanwick (Sherwood Lodge), J. H. Walker (Hardwicke House), T. Edgington (Woodthorpe Grange), J. S. Bellis (Newstead Abbey), &c.

The usual loyal and patriotic toast having been honoured, the Mayor rose, amidst applause, to propose "Success to the Society." He thanked the members for having elected him President for the ensuing year. He felt that every President of a Society like theirs ought to know a good deal about horticultural matters, but in that he was very deficient. He was, however, a great admirer of gardens, gardeners, and all their work. He was greatly indebted to his own gardener, who had endeavoured to teach him much. However, he was ashamed to say that he had so much on his mind with regard to business and town matters, that he frequently forgot the names of the numberless varieties of pretty flowers, which, while they charmed the eye, did not fix their names in his memory. He wished the Society a prosperous season, and hoped they might be successful in their new venture, and hoped it might be instituted at his grounds at Mapperley Park. To him it was a source of much pleasure that they should hold their Show there, and next year he hoped, if possible, to see them with a better Show than before. Mr. Samuel Thacker, in responding, dwelt upon the history of the Society, and made some practical suggestions as to its working in the future.

Mr. C. E. Pearson gave the toast of "Horticulture," and commented upon his experience of horticultural shows and their successful management. The Society had already obtained success by holding one of the best shows in the Midlands, but the success which they had not obtained was success from a pecuniary point of view. If they could not get the public together to look at horticultural produce, they must adopt some other additional means of attraction.

Mr. F. W. Cooper submitted the toast of "The President, Vice-President, and other officers of the Society." He thought previous speakers took rather a gloomy view of the prospects of the Society. The Society had up to the present been connected with genteel horticulture. They had resorted to popular prices, but not to popular pleasures or amusements. The success of the Society very largely depended upon the efforts of its officers, and if they would each endeavour to obtain more subscribers the future success of the Society would be assured.

The toast having been responded to, Mr. H. M. Baines proposed "The Mayor, Magistrates, and Corporation," to which the Town Clerk (Mr. S. G. Johnson) responded in a very energetic address, containing some sound advice to the young men connected with the Society. Mr. Sankey, Bulwell Potteries, next proposed "The Visitors," for whom Mr. Owen Thomas, Chatsworth, responded in a few well-chosen observations.

The Chairman, on behalf of the members of the Society, presented the Secretary (Mr. Edward Steward) with a cheque for £10, in recognition of his services to the Society. The remaining toasts were "The Auditors," "The Ladies," and "The Press."—J. H. W.

NEW SINGLE CHRYSANTHEMUMS.

I AM reminded by a box of blooms of all the newer and best varieties just received of how much Mr. Cannell, of the well-known "Home for Flowers" at Swanley, has done, with his accustomed energy, to popularise

single Chrysanthemums. I have been closely observing what progress towards established popularity they are making. So far the evidence thereof is meagre. They will probably in the future hold the same relation to the doubles that single Dahlias do—both will have their patrons. I find from Mr. Castle's list of new Chrysanthemums of the present year, twenty-four have been certificated in England (*vide* page 464 of the Journal) and of this number not one is single or semi-double. At this time of the year they are, however, extremely useful for cutting or decorative purposes, and there are numbers of people with æsthetic and refined tastes that consider the doubles, as usually grown, "too large and lumpy" for personal decoration; or, as they say, "too like big mop-heads." For the convenience and information of that large class, permit me to try to skim the cream of the newest single and semi-double varieties with which I am acquainted. Of American introduction, we may fitly commence with "America." This, when well grown, can be had upwards of 8 inches across, but smaller-sized blooms are generally preferred. It has a double row of marginal petals, that open rosy blush, gradually changing to white. These are fluted half length. Mr. N. Davis describes it as "early," but the fact of having fine blooms before me as I write shows its variability. A companion variety to this would be "Peter Henderson," large, flat petals, double row, and much the best yellow I know, without excepting even that other fine American single variety, "Helianthus," which is a shade of brighter yellow. Those who require yellows in variety should include Mr. Cannell's Yellow Gem and Mr. Toole, though smaller flowers. Before I pass from the American varieties I must recommend "Harriett Thorpe," a semi-double incurved that opens blush, maturing pure white balls; "Mrs. Allen," deep rose and white ring; and, lastly, Dr. Hogg, distinct from those named, rather semi-double, velvety crimson, smooth, broad petals. Two of Mr. C. L. Teesdale's that should be in every collection are "Mrs. Deane" and "Mrs. J. Mills," the former distinctly Japanese, pure white; and the latter very large, of the same ground colour, chastely suffused with pink. To those may be added the following four that I have grown last year, sent out by the same firm, "Dr. Kellock," silver pink, white ring; "Magenta King;" "Mrs. Langtry," silvery blush; and "Miss Cannell," white, yellow centre. I have seen also some seedlings very large and distinct that more will be heard of.—W. J. MURPHY, *Clonmel*.

CHRYSANTHEMUM SHOW AT FELLING-ON-TYNE.

THE above Show was held on Wednesday and Thursday, 16th and 17th of December, the Committee having organised the Show owing to the disappointment felt at the South Shields Exhibition not taking place this year through the present depression of trade. The Exhibition was small, but some good plants were staged. Mr. T. B. Morton, Howden Bridge, Mr. Fred. Bollam, Axwell Park, and Mr. Robert Charlton, Birtley, were the principal exhibitors with cut flowers.

For twelve incurved blooms Mr. Morton was first with Golden Empress, Queen of England, Empress of India, Lord Wolseley, Princess Imperial, Hero of Stoke. Mr. Bollam was second with excellent blooms of Empress of India, Golden Empress, and Jardin des Plantes. For twelve reflexed blooms these exhibitors were in the same position; also for twelve Japanese, Mr. Morton having fine blooms Fair Maid of Guernsey and Criterion. Mr. R. Charlton won the first prize for six Japanese with flowers 8 inches across of Fair Maid of Guernsey, Erectum Superbum, and Gloire de Toulouse. For six flowering plants Mr. Paul Blanchard, gardener to Dr. Gibb, Sandyford Park, Newcastle, was first with well-trained plants of Mrs. G. Rundle, G. Glenn, and Mrs. Dixon. The same exhibitors were also first for three Pompons, three Japanese, and two Anemone-flowered, followed in each class by Mr. Russell, a local amateur, who exhibited plants.

The Exhibition on the whole was very good for a commencement, considering that the Committee only thought of it three weeks ago. The Committee and Hon. Secretary, Mr. W. Simpson, jun., are to be congratulated on their success.

ROYAL METEOROLOGICAL SOCIETY.

THE usual monthly meeting of this Society was held on Wednesday evening, the 16th inst., at the Institution of Civil Engineers, Mr. R. H. Scott, F.R.S., President, in the Chair.

Mr. J. Hartnup, Mr. A. W. Preston, Mr. R. Sheward, and Mr. W. B. Worthington, B.Sc., M.Inst.C.E., were balloted for and duly elected Fellows of the Society.

The following papers were read:—(1) "On the Influence of Forests upon Climate," by Dr. A. Woeikof, Hon. Mem. R. Met. Soc. The first step towards a scientific investigation of the influence of forests upon climate was taken by the establishment of the Bavarian forest meteorological stations. The example was followed by Germany, France, Switzerland, Italy, and other countries. As a general result it was found that during the warmer season the air and earth temperatures were lower in the forest as compared with contiguous woodless places; that their variations were less, and that the relative humidity was greater. Dr. Woeikof's discussion of this question shows that in the western portions of the Old World extensive forests materially influence the temperature of neighbouring localities, and that the normal increase of temperature from the Atlantic Ocean towards the interior of the Continent is not only interrupted by their agency, but they cause the summer to be cooler in regions situated further in the interior than those nearer the sea. Hence forests exert an influence on climate which does not cease at their borders, but is felt over a greater or less district, according to the size, kind, and position of the forests. From this it naturally follows that man, by clearing forests in one place and planting others in another, may considerably affect the climate.

(2) "Report on the Phenological Observations for 1885," by the Rev. T. A. Preston, M.A., F.R. Met. Soc. The year has been a very dry one, and this has acted in such a manner on vegetation, that although the winter was mild, plants were very late in flowering and lasted only a short time. The bloom was often profuse, and as bees and other insects could visit them,

the crop of fruit was unusually great, the Apples, for instance, being often spoilt in quality from the enormous number on the trees, whilst in the case of wild fruits the brilliant colour of the bushes when in fruit was quite as beautiful as when in bloom. But at the same time the drought acted very prejudicially, especially to root crops and bush fruit, as well as Strawberries. In the case of the root crops the seed had great difficulty in germinating, and the weak plants were at once overpowered by insect pests, so that the crops of Turnips were generally complete failures. The insect pests also did much damage to bush fruit, while the drought prevented the Strawberries from swelling. The corn did not suffer to any great extent, the dry season allowing the land to be prepared, and although the straw was often short, the yield was not unsatisfactory. A general absence of butterflies was noticed in some places. In the south of England the white butterflies were most abundant at one time, but the autumn butterflies were not so plentiful as usual.

(3) "Etudes sur les Crépuscules Rosées," by Prof. A. Riccio of Palermo.

(4) "The Storm of October 15th, 1885, at Partenkirchen, Bavaria," by Col. M. F. Ward, F.R. Met. Soc. This was the most destructive storm which has occurred in this valley since the winter of 1821-22. The storm burst suddenly at 7 P.M., and lasted about half an hour, but in that short period nearly every house was unroofed, and it is computed that in one forest alone above 250,000 trees were laid prostrate.

CHRISTMAS BERRIES IN THE OPEN AIR.

BERRY-BEARING plants in pots which have partially grown and wholly matured under glass are very pretty and desirable at this time, but there is not one in a thousand of those who use evergreens and berries for Christmas decorations who have the means of growing them, but there are hundreds of those who cannot do so that might cultivate a few bushes which would supply them with berries at Christmas. Although all kinds of open-air berries are uncommonly plentiful this season we often hear of their being scarce; but that applies more particularly to the Holly, as when there is no fruit on this some appear to conclude that there are no berries, but by growing a small selection of berry-bearing bushes there will always be some of them in fruit at Christmas. It is a pity that those who plant a few scores or hundreds of shrubs in a small garden do not pay more attention to berries. The general desire is to plant those that will flower in spring or summer, when all kinds of blossoms are most common, and then the flowering bushes are looked on as being of no special value; but now when we are in the dead of winter, and open-air flowers have quite disappeared, those bunches which bear berries become very conspicuous and valuable. Winter effect in planting should always be more studied than summer display, and where this good rule is followed berry-bearing trees will be largely used, and their possession will be hailed with delight at this time and throughout the winter. They require no special soil situation over and above that given to any other trees, and they are no more expensive at first. Generally speaking, they will grow in all soils and situations. The winter months, from October until March, is the time to plant, and any nurseryman will supply them in quantity.

The Hollies are not very quick in growth, but they are remarkably hardy. They are sometimes just a little difficult to transplant, but this mainly applies to many large specimens, and little nursery plants from 2 feet to 4 feet in height may be planted as successfully as almost any other bush. The common green variety is as good as any to produce berries. *I. ferox* is the Hedgehog variety, but not a free-fruiter. *I. fructu-luteo* produces yellow berries, and should always be introduced for the sake of variety. *I. argentea variegata* is the silver-leaved variety, a great beauty and a free fruiter. This should never be omitted. *I. aurea maculata* and *I. aurea Regina* are the Golden Hollies, and although very pretty they are not specially fruitful. They are useful, however, for Christmas decorations apart from any consideration of berries.

The Aucubas are well-known evergreens. They are extremely hardy and useful, as they grow in towns as well as in the country. By planting a male variety amongst female sorts the latter will become covered with beautiful scarlet berries of great size and value at this time. In this respect they are unrivalled.

The Arbutus, especially *A. Unedo*, is a beautiful object now. The trees are surrounded with little clusters of creamy bell-shaped flowers and Strawberry-like fruit. They are the largest of all Christmas berries. They grow well near the sea, and succeed admirably amongst a general collection of bushes. The Sweet Bay produces berries very freely here. They are about the size of peas, oblong, dark purple in colour, and cluster round the points of the shoots. The Laurustinus also produces berries very like the preceding. They are a little smaller, and are clustered together in terminal bunches. Cotoneasters are pretty evergreens, which produce red berries in winter with absolute certainty. *C. microphylla* is the small-berried sort, very prolific, and good for the front of shrubberies, walls, or rockworks. *C. Simonsii* grows taller, is more of a bush, and bears larger berries of a very charming character. *Pyracanthas*, especially *Crataegus Lelandi* and *C. fructu-luteo* are exquisite winter-berried plants. They are quite hardy and well adapted for walls and trellises. Their large effective berries remain on the whole of the winter, and those who introduce one plant of each or more will never be without Christmas berries, as I never knew them to miss a crop.—J. M.

HOW TO FILL AN ICE HOUSE.

IN reply to "J. R.," who asks for information on this subject at page 539, I beg to say that some non-conductor, such as Wheat straw or sawdust, should be placed in the bottom of the ice house, and between the walls and the ice, as the work of filling proceeds. Assuming there is a brick or concrete surface outside the icehouse door for tipping the ice

from the carts on, it should be broken thereon with mallets before begin shovelled into the house, where it should be repounded and rammed together, and boiling water applied as advised in the making of ice ricks at page 534. In order to secure a good supply of boiling water for the purpose of consolidating the ice by its frequent application during the process of filling the house, it will be necessary to temporarily erect a boiler on a few loose bricks close by. When the house is filled a thick covering of the same material as that put between the walls and the ice should be put on top of it, and the passage leading to the house from the outer door should be rendered air-tight by placing closely together therein several bundles of clean straw.—H. W. WARD, *Longford*.

HYDRANGEAS.

CONTINUING as promised my remarks upon the culture of Hydrangeas, the following system of treatment will be found a good one.

At the commencement of the year, or even earlier, these plants can be started into growth. A vinery or Peach house just started is a capital place for them. As soon as they commence growing they are arranged on a shelf close to the glass to keep them as dwarf as possible, for if some distance from the glass they are liable to become drawn. As soon as the flower truss is just visible the plants may be transferred into 6-inch pots, the smallest size it is possible to shift them into. At one time I was under the impression that this treatment assisted them wonderfully in developing their gigantic heads of bloom. The practice is now abandoned and our plants are not potted, the trusses of bloom being equally as large as before. The treatment now is to top-dress with a little cow manure and sprinkle upon the surface of the soil two or three applications of Standen's manure during the time the heads are developing. This treatment insures dwarf plants from 1 foot to 15 inches high, with trusses 10 inches or more in diameter, provided they are not expanded in too much heat or grown in too confined an atmosphere. After the flowers are visible an intermediate temperature should be provided and air admitted freely whenever outside conditions will allow of this being done. The flowers are a long time in developing even after they are visible, and this batch of plants can be divided when they reach this stage for the purpose of forming a succession. The plants to be retarded should be gradually given cooler treatment until they can be placed in the greenhouse, and if allowed to expand their flowers under these conditions they will form a capital succession to those pushed forward in heat.

Those rooted at this season of the year are allowed to make a start under similar conditions to those already advised, and are then placed into 4-inch pots, using the above compost. These will produce equally as fine trusses as those that had been grown during the previous season. The plants may be divided and started into growth at intervals of a month, according to the demand. The last plants should be started in the cold frame, and may finally be divided and a portion placed outside. The amateur may start his first plants on a shelf in the greenhouse, leaving the remainder in the cold frame. A portion of those started in the greenhouse can be placed in the cold frame after the flowers show, so that they will come into flower after those in the greenhouse have faded. Those left in the frame may also be divided and a portion placed outside, which will insure a long succession of plants in bloom either for room-decoration or the greenhouse.

The varieties most suitable for this purpose are *H. hortensis*, *H. Otaksa*, and *H. Thomas Hogg*. The last-named is more slender in growth than the two former, and produces pure white flowers, which are admirably adapted for cutting and bouquet-making. This should be grown in all gardens, for it is the finest of the Hydrangeas. The second named is a magnificent rose-coloured variety, and produces very large trusses of bloom, and should certainly be largely grown where these plants are appreciated. The old *H. hortensis* cannot be despised, for it is decidedly one of the best for general purposes. Its flowers and trusses are both large when well grown. It is very changeable in the colour of its flowers, which naturally are of a rosy hue, but very frequently heavily shaded with blue. Sometimes the flowers come quite blue, and whether of this colour or shaded they are even more beautiful than when they come their natural shade. There are many speculations as to the cause of this blue colouring in the flowers, some believing it is due to the feeding they receive in the form of stimulants, others to the soil in which they are grown. There can, however, be no doubt that when iron exists in the soil the flowers are shaded more or less. Blue flowers, however, cannot be relied upon, for if cuttings are taken from one plant and the whole treated exactly the same as regards stimulants and soil some will be rose in colour, while others will be blue or shaded. The flowers of the variegated form of this variety very frequently come blue, and when they do they are charming; the contrast of the white variegation of the foliage and blue shaded flowers are very effective. This form is well worth growing for various purposes of decoration on account of its foliage, which when forced early in the season is very beautiful grouped with other plants.

H. paniculata grandiflora should also be grown in pots, for it is really charming with its large panicles of creamy white flowers, which are most freely produced under good cultivation. This requires slightly different treatment from *H. hortensis* and its varieties. For growing in pots strong plants should be obtained to commence with, imported plants generally being the best. These cannot be obtained for some time yet, but should be obtained as early as possible, and be placed into 6 or 7-inch pots in the same compost as recommended for other varieties. Partially prune the stems and plunge the plants in a cold frame. In spring, just before growth commences, prune the shoots closely back. If one eye is left on each shoot of the last season's wood it will be sufficient. Encourage them to

grow under cool frame treatment until the roots are active, when the plants can be removed to the greenhouse and allowed to come naturally into flower. No attempt must be made to force them the first season, or the growth will be weak, fail to flower, and the plants probably be ruined instead of being thoroughly established for the following season.

After flowering they may be placed outside, the principal object being to get the wood thoroughly ripened, for upon this entirely depends whether the plants flower well or the reverse. The shoots should be pruned closely back any time during the winter prior to starting the plants into growth again. This season the plants may be gently forced, but a warm close confined atmosphere must be avoided or the growths will grow weakly and fail to flower. Plenty of air must be admitted to insure sturdy compact growth, and then fine flowers will be the result. The plants should be top-dressed when introduced into heat, and freely supplied with stimulants after growth has once commenced.

This is a beautiful plant for decoration, and can by gently forcing be trained to flower months before its natural flowering time, which is from the end of August. It cannot be forced into flower so early as the varieties of *H. hortensis*, but by starting it into growth a little earlier each successive season no difficulty will be experienced in inducing it to flower moderately early in the summer, when it proves invaluable for the conservatory.—B.

KITCHEN GARDEN.

FORCING is the main consideration just now. Our produce grown in this way for Christmas consists of Asparagus, Seakale, and Rhubarb. We find roots force uncommonly freely this autumn, and the growths are both abundant and of high quality. Those who refuse to force anything early in the autumn under the impression that it cannot be done profitably then may begin now with safety. Rhubarb is forcing readily in the ground with a hotbed over it. One day some of our men covered three large crowns. They put the casks upside down over them, and then covered them all with hot manure. When we looked inside ten days afterwards we found the growths had sprouted about 2 inches and then perished. The cask being made air-tight by having the manure on the top the steam had no means of escaping, and failure was the result. Others with the top arranged so as to admit a very little fresh air and allow the steam to escape are going on well.

Seakale may now be covered, but remember to provide a little ventilation. Where there are old-fashioned Asparagus beds with deep pigeon-hole brick pits between for filling with fermenting material some of them may be started; but it is not wise to begin this system of forcing too early, as the growths, although covered, may become so tall before April that they will be severely checked. We certainly prefer lifting the roots to this plan. Kidney Beans should be put in largely, as those sown now will only come into fruit about the beginning of March, and that is a time when they fruit very freely. There is no better way of dealing with them at this time than by putting six or eight seeds into a 3-inch pot, and potting or boxing them on as they grow large and become ready. We have ceased to grow Kidney Beans for Christmas use, as they fruit so sparingly at this time that we could not grow them with any degree of profit, and we find it more satisfactory to devote our glass houses to the culture of other things.

MUSTARD AND CRESS.—We keep up a daily supply of this now. Those who sow it are perhaps not always so careful as they ought to be, the general impression being that the seed will germinate and the crop prove satisfactory in any kind of soil, and this leads to any old soil being used. Now and again we have found some of our shallow boxes which were filled with any old soil just manage to throw up the young plants, and then patches here and there would die. This, even with Mustard and Cress, was not satisfactory, and in looking for the cause we found that very old potting-shed soil had been used. Some of it had been pressed down very firmly, but in other parts it was loose, and it was these spots that had failed. Since then we have filled the boxes with pure leaf soil, ramming it down firmly, and now we have the finest crops of Mustard and Cress we ever possessed in winter. Both the leaf soil and the extra firmness of it seem to be beneficial.

POTATOES.—Those which have been stored for some time should be uncovered, turned over, and any bad ones picked out. Early Kidneys which have been lying spread out thinly in a bottom shelf in the fruit room have begun to sprout rather freely. Those we want for frame planting early in the year will be allowed to advance, but the others which will be kept for the first plantation in the open will have the longest of the shoots brushed off and be allowed to restart before planting. Were the shoots now on allowed to remain, they would be much too long by planting time. When it is frosty the desire is to cover the seed tubers as well as possible, and this is right; but when a thaw sets in and mild weather comes the thick coverings often allowed to remain. This causes the growths to spring up rapidly, and the result is much injury to the sets. Cover by all means in frosty weather, but be as particular to uncover when it is mild.

HOTBEDS.—These will very soon be required, and all the material for

their formation should be prepared. Collect leaves, old vegetables, and littery manure of any kind; mix them all together, throw them into one heap, turn this every three or four days, and by the beginning of January a hotbed may be made up, which will produce early Carrots, Potatoes, Radishes, or anything which may be desired. A hotbed is the most useful thing anyone can have in a garden in the spring months, as propagation and other things may be done in it, and the main point is to secure plenty of material to make it with. Where leaves and straw manure are short, Cabbage, Savoy, and other vegetable stumps and leaves are a great help.

JERUSALEM ARTICHOKEs.—Although these are not grown in every garden, we regard them as one of our very best winter vegetables, deserving more extensive cultivation. The roots can be used in many ways, and many persons enjoy them as a vegetable pure and simple cooked like Potatoes. When planted in rows in the spring they soon emit side shoots, which grow up and make it difficult to tell where the rows are, and for this reason it is necessary to dig up every winter and plant every spring. They ought to be all dug now, putting a quantity of the smaller ones to one side for replanting, and storing the others like Potatoes for use. They keep well for months, and those dug up now will be quite good until May or later.

WALKS.—This is a good time to see that walks are in proper order. A kitchen garden walk ought to be a thoroughly good one. When they are not well made the wheeling which has to be done on them very soon puts them out of shape, and makes them puddly in winter and uncomfortable at all times. Large stones should form the foundation, smaller ones should top these, and gravel or ashes should crown all. Altogether, these materials should be 1 foot in thickness at least. Where old walks are out of form, pick them up; pull the small material to one side, place some rough material in the centre, and throw the fine from the sides over the top again. All walks should be a little higher in the centre than at the sides, and although some may think any kind of path will do in the vegetable garden, good and well-kept pathways are both ornamental and useful.

TOOLS.—These are not used so much at present as they will be in a few months, and now is the time to have broken ones repaired and new ones got in where required. This applies to hoes, rakes, baskets, and, in short, everything. On some estates borrowing of tools goes on, and every new tool we bring in is at once branded "garden."

FRUIT FORCING.

PEACHES AND NECTARINES.—*Earliest-forced House.*—Forcing operations having been impeded by the cold in the early part of the month, the buds are not so forward as usual; but where the roots are inside, as those of all early Peaches should be, the buds are swelling strongly, some showing colour, and the night temperature should not fall much below 45° on cold nights and 50° on mild nights, with a rise of 10° to 15° by day, but nothing is gained by being in a hurry until the length of day is considerably increased, when any apparently lost time will be more than made up by trees that have been carefully treated, and even kept back through the early stages when the weather was against them. Trees that are allowed to unfold strong blossoms in a low temperature, particularly at night, with free ventilation and in good condition at the roots, invariably set well and stone satisfactorily, as might be expected, through the energies having been husbanded, finishing good crops of fine fruit in a higher temperature than is usually given. A high temperature at the beginning is often fatal to the crop, and jeopardises the future by inducing weak wood, but by proceeding gently the trees make strong short-jointed wood, and due regard being had to thinning and other details of management, the trees are profitable and remain so during an ordinary lifetime. Great crops are had at the expense of size and quality, the occasional loss of a crop, and the premature destruction of the trees. Maintain a moderate degree of moisture in the house by damping available surfaces in the house occasionally, but avoid wetting the blossom after the anthers show clear of the petals.

Second House.—Where three or more houses are forced annually the second should be ready for starting on New Year's Day. Whatever is needed by the house, trees, &c., in cleaning or repairs, should be attended to at once, and the lights, if off the roof, replaced. Fire heat need only be used the first fortnight to exclude frost at night, but the heat should be turned on in the morning to raise and maintain through the day a temperature of 50°, and ventilation so as to insure a change of atmosphere, not allowing an advance above 55° without full ventilation. The trees should be syringed in the morning and again in the afternoon early, so as to allow of the trees becoming fairly dry before night. It is a very common practice and great error to allow the inside borders to become dry in the autumn and through the early winter months, which is generally followed by the casting of the buds, particularly the most prominent and promising. The borders being composed of good loam resting on efficient drainage, there is little danger of their receiving too much water, either by throwing the houses open to the autumnal rains—a most excellent practice—or by giving them liberal supplies artificially.

Succession Houses.—Proceed with dressing, pruning, and tying the trees, and cleansing the houses. Remove the inert surface soil, and supply fresh loam, to which has been added a sprinkling of bonemeal and some wood ashes. Ascertain that the borders are thoroughly moist. Keep the house as cool as possible, and if the weather prove very bright it is well to shade if possible so as to keep the blossom back, especially in the case of late houses. This is a very important matter, and though common with old gardeners is little practised now. The swelling of the buds through a spell of mild weather and afterwards kept stationary for weeks through severe weather, is very injurious to the crop, often fatal

as the buds fall, or they expand very puny blossoms which set badly, and the fruit setting swells very irregularly and a large per-centage is cast in stoning.

CUCUMBERS.—Let every opportunity be taken to husband the sun heat by early closing in the afternoon, damping at the same time with tepid water. In bright weather the plants may be slightly sprinkled through a fine rose, and the pathways must be sprinkled every morning, otherwise red spider will be troublesome. Liquid manure in a weak state should be given to plants growing freely, but the plants being at a standstill it will be advisable to withhold the liquid manure until they are showing free growth, it not being of any use to give liquid manure to plants that have few feeders or little activity at the roots.

Hotbeds for Raising Cucumbers and Melons.—Fermenting materials having been mixed as advised, and having been turned twice to generate a uniform heat and to allow of the rank heat escaping, it will be ready for making into a hotbed at the end of the month, which should be done in a southern aspect, and in front of a Privet or other hedge, so as to break the force of the north wind and prevent its driving into the back of the frames when air is admitted. The ground on which the hotbed is made should be higher than that surrounding it, so as to prevent water lodging under the bed, and if the site be low the bed should be made on a layer of faggots. The bed should only be made so large as to take the frame and allow of about 3 inches all round, so as to allow of linings telling effectively when applied. The dung and leaves should be well beaten down with a fork as the work proceeds, and make the bed sufficiently high to allow for settling, which will be about a third; therefore it will need to be about 6 feet high at the back and 5 feet in front to begin with. It is an old and capital plan to place a few layers of pea sticks across and along the bed for conducting the heat supplied by the linings to the interior of the bed. It is also a good plan to put a shell inside the frame of half-inch deal boards, so as to form a cavity of an inch between it and the side of the frame, and 6 inches shallower than the frame, which will afford a means of admitting top heat. Put on the frame, and when the heat has risen level the surface if unequal, replace the frame, and put in sufficient fermenting material to make the depth of the back part equal or corresponding with that of the front, and on this 2 or 3 inches of short material. About 4 inches of dry leaf soil or sawdust in which to plunge the pots containing seeds as soon as the heat is up to raise young plants. Such a hotbed is very useful, and properly made and attended to is perhaps the most useful in a garden during the spring months for propagating purposes.

PLANT HOUSES.

Cyclamens.—If these are not coming into flower fast enough under comparatively cool conditions, place them on a shelf close to the glass in a temperature ranging from 50° to 55°, where a circulation of air can be maintained when the weather is favourable. If this is done they will come quickly into bloom, and their flowers will be thrown well above the foliage. These plants must never suffer by an insufficient supply of water at their roots in any state of growth. Weak stimulants may now be given every time water is needed to all plants that have filled their pots with roots. Where young stock is grown on annually for decoration, those plants used in rooms and other similar positions may be thrown away directly they cease flowering, for they rarely do any good another year. Those that do retain them for flowering another year must keep the plants after flowering in a cool light position, and supply them regularly with water. Young stock now in small pots for another year must be kept slowly moving in a temperature of 45°. They must be arranged close to the glass, and ventilated whenever favourable to insure a slow but sturdy growth. Plants of the same size still in pans must have the same treatment, and directly after the new year they should be placed singly into small pots, so that they can afterwards be shifted into 3 and 4-inch pots. Seedlings just coming up must be kept moist and close to the glass, for these will make valuable flowering plants if looked after before the close of another season. Those that have not sown seed should sow it at once in light soil in pots or pans, the seed being lightly covered with fine leaf mould. After this the soil should be watered and covered with a square of glass, and then placed in a temperature of 60° to 65°.

Primula obconica.—The seed of this plant is a long time germinating, but it is such a free-flowering plant that where decorative plants are required in 5-inch pots a good number should be grown. Plants raised from seed as soon as it was ripe are still in pans, but ready for small pots, in which they may be placed without delay. These may be grown under glass until they are placed into 6 and 7-inch pots, and they will flower profusely through the whole of next winter. This plant does well in a cold frame during the summer, but if this cannot be given it the plants will do very well outside after they are once placed in their flowering pots. For the present the young plants should be grown on in an intermediate temperature. Another pan of seed should be sown at once for flowering plants in the smallest size pots named. Fill the pan with light soil and sow the seed on the surface and not covered with soil. Water with a fine-rose can, and then cover with a square of glass until germination takes place, which will take some weeks in a temperature of 60°.

Fern Spores.—Where quantities of Ferns are required for decoration in small pots it is necessary to raise suitable kinds by sowing spores. Small plants raised by this means are always much more handsome and shapely for these purposes than it is possible to have them by division of larger plants. Spores are easily saved by the removal of mature fronds from varieties that produce them freely, and, spread upon a sheet of paper to dry,

the spore cases soon burst and the spores are deposited on the paper. Pots 5 or 6 inches in diameter should be liberally drained and then filled with equal parts of loam and peat, with a liberal dash of sand added. The surface should be made fine and even, and the spores sown at once on the surface. If they are covered with soil failure will be certain. They must be watered with a fine-rose can, covered with a square of glass, and the pots plunged in some moist shady corner in a stove or intermediate temperature. Care must be taken that neither the soil or the surroundings of the pots become dry, and then a good number of seedlings will be certain to appear in due time. At first they appear in the form of a coating of green on the surface of the soil, which develops in size until a tiny frond is put forth. This must not be removed. When the sporplings are large enough they must be pricked out singly into other pans or boxes, and finally potted into small pots. Another good plan of raising sporplings is to place under large plants pieces of half-decayed turf, which can be kept moist without having to be constantly watered or syringed, and upon these the spores will fall, and in due time a good quantity of young Ferns will be produced without further trouble.

THE FLOWER GARDEN AND PLEASURE GROUND.

Protection from Frost.—We have already had some experience of winter, but the frost was not long-continued nor very penetrating, consequently it was easily kept out of the frames containing bedding plants. It is advisable, where not already done, to prepare for more severe and more lasting frosts, or many moderately hardy plants in frames may be seriously injured. The best protecting material we can procure is rough strawy stable litter, and this abundantly and freely used will usually keep out the most severe frosts. Mats being available, these may be thrown over the glass before the litter is put on, and the combination will certainly keep out the most severe frosts. Without litter, the mats must be used two or three thick, and even then, if at all wet, may not keep out the frosts. Some use portable straw mats and thatched hurdles, and these are effective, but we would still prefer plenty of dry litter. The sides of both brick pits and frames should also be surrounded with a good thickness of leaves or litter, not a chink of any sort being left open for the frost to penetrate. Any hardy pot plants, for which there is not house or frame room, should have the pots plunged, or heavily surrounded with either leaves, ashes, or rough litter, or otherwise the frosts will crack them, and maybe also injure the roots. Tea Roses in positions where they are much exposed to cold frosty winds ought to receive some sort of protection, or otherwise they may be killed down to the ground. Those planted at the foot of walls of any kind may be sufficiently sheltered with either a single mat, branches of evergreens, or, better still, branches of Spruce Fir. Failing these, the trees may be unloosened from the walls, bunched up, and protected with haybands or a heavy layer of rough strawy litter or dried Fern fronds. Those in the open ground, including any newly received, and laid in "by their heels," as previously advised, should, whenever a severe frost is imminent, be heavily surrounded with rough dry litter, a good quantity of the same material being thrown over the plants. It is the lower portion of the plants, however, that it is of the greatest importance to protect, as if the tops are damaged this may be pruned away to the sound portions, the plants, in some cases, being strengthened by this perhaps unusual shortening. Snow affords capital protection against severe frosts, thousands of dwarf Roses sometimes being killed down to the snow line only. Those who have lost the greater portion of their Roses do not mind how much trouble they take to guard against a recurrence of this disaster, and a good practice is to mound up the snow round their pots, and it must be a severe frost that penetrates through this. Standard Roses are not so easily protected. It is the Briar stocks or stems that are the soonest injured, and in districts where these cannot be relied upon we would advise that they be bound with haybands or neatly surrounded with straw. This practice may not suit the ideas of the majority of our readers; but if this is too laborious the least that can be done is to heavily mulch the ground with rough litter, this not unfrequently saving many trees from total destruction. Any choice bulbs not perfectly hardy that may be left in the ground—these including Lilliums, Gladioli, Dahlias, and even Begonias—may well be heavily covered with ashes, this effectually protecting them from severe frosts. Christmas Roses are very hardy, but the blooms, which this season are rather early, are soon disfigured by either frosts or rains. Where they are planted in heds a spare frame should be placed over them, while single plants may be covered either with bellglasses or handlights. A further covering of mats or litter will preserve them from severe frosts, and the result will be a long succession of nearly pure-white blooms. All newly planted trees or shrubs should receive a heavy ground mulching of rough manure or litter, otherwise many of the roots may be killed, and a second severe check be administered.

Treatment of Frozen Plants.—If by any chance the plants in frames or houses become frozen, much care must be exercised in recovering them or they will be lost. They must be thawed very gradually, and as much in the dark as possible. House-grown plants may be stood under the stages, freely syringed with cold water, after which they should be surrounded with mats or blinds, and, thus darkened, they may be allowed to gradually recover. The temperature of the house to be gradually raised, and if there is insufficient piping to keep out the frost during the next night, the plants ought to remain where they were put to thaw, and further protected if need be. When it is found that the frost has reached the plants in pits or frames it is not advisable to syringe these, especially when they happen to be Zonal Pelargoniums or other plants that are liable to damp off, but they should be kept quite dark during the first day after the frost has broken, and afterwards gradually exposed to the light.

Unless very badly damaged this treatment will recover them. Low temperatures, especially when the weather is damp and close, are frequently more destructive than frosts, so many of the plants being liable to damp. At this time of the year little or no water should be given to any of the plants in cold houses or frames, as when dry at the roots they are much less liable to be injured either by frosts or damp. Neither should those plants in slightly heated houses be encouraged to grow much, as in this case the growth is almost certain to be weakly and unsuitable for striking later on. The more hardy sorts should receive plenty of air whenever the outer atmosphere is fairly dry, and advantage should be taken of dry days to examine all the plants in pits and frames, from which any decaying leaves ought to be removed and any decaying portions of stems be cut away, this naturally preventing a further spread of the evil. Alternantheras, Coleuses, and Iresines wintered on shelves or spare stages of forcing or other well-heated houses, must also be carefully watered, especially if they are not well rooted, the first-named in particular frequently becoming much stunted in growth unless very carefully treated.

THE BEE-KEEPER.

FOUL BROOD.

WHILE the bee-keeping world have their attentions upon the cause and cure of the above malady (now designated *bacilli alvei*), it may be appropriate to refer to the subject. It appears foul brood was known to exist at a very early date, and was well known to the ancients; but probably the Scotch derived their information at first from their countryman, Bonner, and took his advice, using caution before purchasing any hive, so that foul brood might not be present; deriving their information from experience, too, that feeding bees with foreign honey, foul brood followed. Such information would have prevented any Scotch bee-keeper of note making so great a mistake as did the late Mr. T. W. Woodbury by both purchasing affected hives from cottars and feeding with foreign honey, which ruined his apiary. Those bee-keepers who assert that the introduction of foul brood is due to Ligurian bees should take a note of that. Much as we all regretted Mr. Woodbury's loss at the time, good sprung from it and the discussion thereon, although much of it was fruitless. Many were the causes assigned, and the cures were no less in our own country as well as on the continent. The Germans attributed the disease to pollen, and one great master amongst them assured us that the origin of foul brood would never be discovered by any but a man of science. At that time, though perfectly cognisant that stifling bees in a humid atmosphere and overheating was followed by foul brood, I did not altogether refrain from following the popular belief that chilled brood had something to do with it. So mysterious did the disease work that I was, like many others, driven to my wit's end. I was led from circumstances to suspect the queen of being the author of the disease. Being in correspondence with Mr. Woodbury at the time, I made the suggestion to him, and had a reply through this Journal that caused me to wish I had thought twice before I submitted the question. Shortly after that Mr. Woodbury experienced a new disease which he termed dropsy, and simultaneously I had several bad cases, which I communicated and commented on, our views being then similar. Since then I have experienced many cases of the same disease, and from its nature have termed it "chlorine dropsical fever." Bees affected with this disease soon die. At a time when it threatened my apiary with destruction I sent some of the bees to a professor of natural science, but unfortunately the answer was contrary to facts. The above disease never proved infectious, but is hereditary. Neither in any of the above cases, nor with those having diseased queens, have I ever found foul brood follow or accompany it.

During the height of the discussion I turned my attention to it, endeavouring to solve the problem, and having previously been experimenting with milk in the transmission of disease, I applied it to foul brood and had satisfactory results as to its origin. My next attempts were to propagate the disease by inoculation and testing under what temperature

it reproduced itself soonest, which proved that heat was more favourable towards its development than cold, especially when there was much moisture present in the hive. After these discoveries I made a radical alteration in all my hives by giving more ventilation and more room; and taking the hint given by "R. S.," a Dumfriesshire clergyman, about carbolic acid being a quieter and disinfectant, I am glad to say that ever since my apiary has had an almost entire immunity from the disease. That foul brood is not common and natural to a hive, but accidental, I firmly believe; if it were the former it would be contrary to all nature, and bees would consequently very soon become extinct, because they could not rid themselves of it. There is nothing in nature but has been provided with some means of self-preservation against common enemies.

Notwithstanding all that has been written on the subject the cause of the disease is still problematical. Some say it is in the honey, others the pollen, while others point directly to the germ theory, which I believe to be the effect rather than the cause. I am also of the opinion that its origin must be sought for in the two first-named ingredients, and take for proof that I am correct in that in the hundreds of hives that have been cured by the "purgatorial" process described by "A Renfrewshire Bee-keeper." Although it was my opinion at one time that foul brood might be communicated by a queen whose organs were infested by germs in a state of development suitable for rapid reproduction, I do not entertain that opinion now, because a queen whose organs are diseased cannot survive long, owing to the rapid waste of animal tissue brought about by the presence of bacilli. Eggs would cease to be laid, and the hive would either perish or a young queen would have either to be supplied by the bee master or bees, after which the disease would go on unabated.

What is, then, the cause of foul brood? It is a change that is undergone in the food of the larvæ, depriving it of the power of sustaining life. How these changes so destructive to life are brought about are best explained in the following example. A heap of fresh grass is laid before a cow in good health and in milk. She eats it, and in a few hours it is digested, and part of it secreted as milk and blood, which nourishes the body, sustaining life and giving heat to the animal. If the cow is allowed to suckle her calf it will not only live but grow rapidly on Nature's food when taken in a natural way; but if a portion of the same cow's milk be drawn from her and set aside for a time under certain states of the atmosphere, a change takes place, and if that milk be given to another calf, instead of it acting as food will act as a poison, and the calf will die. That is a fact, and we see the same occurring often amongst the human family when meat in an unwholesome state has been taken—wholesome to-day but poison to-morrow. A similar change in the food of the larvæ is, I believe, the cause of foul brood. The food of the larvæ is composed of honey, pollen, and water, which singly may be wholesome, but when mingled through some previous transition from overheating or other cause prejudicial to the contents of the hive, bacilli of some form become active, and the mischief is done.

There is one thing of importance in connection with the queen and economy of the hive which I think will help to solve the question of foul brood. In all my experience I never knew eggs prevented from hatching through the presence of disease, owing to so many eggs being deposited by a queen or queens, and which are never hatched. Some people may differ from me, but I have satisfied myself on that point. If eggs contained bacilli I think many of them would never hatch. In fact, it has been observed that queens in hives affected with foul brood are liable to deposit not only healthy-looking eggs, but many of them, which brings me to a point to consider the whole question of egg-laying. Until the fertilisation of a young queen she is not attended to much by the workers, but is allowed to feed herself. Immediately after fertilisation she receives much attention, and is lavishly fed by the bees. Now, what is this food composed

of? Not of honey alone, I should think, but similar to that required for the larvæ. I do not think a queen could produce eggs at all, nor the great number required, besides keeping up the tear and wear of the body, on honey alone. We often hear people speaking of feeding bees to promote breeding, but without pollen it has no effect, though some deny this. The queen has always to be fed, but where pollen is absent no eggs are laid, nor does she show signs of a desire to lay; but when fed by the bees she cannot prevent it, and in that state drops many eggs, showing she cannot control it. This control belongs entirely to the bees, and illustrates well how they economise the eggs by feeding sparingly early in the season, increasing the feeding as the year advances, and withholding it altogether in the fall. If queens could voluntarily bring on laying without extra prepared food they would never cease laying until they were entirely exhausted. When bees are fed at an untimely season it hastens the death of the queen. When a queen is fed with pap made from the contents of a diseased hive it may account for the presence of bacilli in her body.

I think the whole question of foul brood lies in a nutshell. It is brought about by some change in the nature of both honey and pollen, or in the pap if placed too early in the cell; but when a hive is once affected the disease may be communicated by touch. It may either be acute or chronic, and when in the latter state may exist for years in a hive unfavourable to its development before it breaks out with virulence. But in either case the bee-keeper will study his own interest best, as well as that of his neighbour, if he stamps out the disease by destroying the contents of the hive and subjecting the bees and queen to a rigid purgatorial process, allowing sufficient time to elapse so that both bees and queen will have exhausted the contents of their stomachs before putting them into their permanent hive. When this treatment was properly performed I never knew a single case of failure.

The boiling of honey taken from an infected hive does not prevent it communicating the disease afresh. I have expressed my candid opinion on the cause of the disease, but I shall be glad if anyone will bring forward evidence to prove or refute my arguments.

ERRATUM.—At page 505, first column, last line but one, "than a dozen" should be "than half a dozen."—LANARKSHIRE BEE-KEEPER.

TRADE CATALOGUES RECEIVED.

James Veitch & Sons, Chelsea, London.—*Catalogues of Garden and Flower Seeds, Roses, Fruit Trees, and Chrysanthemums.*

B. S. Williams, Upper Holloway, London, N.—*Catalogue of Flower and Vegetable Seeds.*

William Etherington, Swanscombe, Kent.—*List of Chrysanthemums.*

Lawson Seed and Nursery Company (Limited) Edinburgh.—*Catalogue of Forest and Ornamental Trees, Shrubs, &c.*

Chr. Lorenz, Erfurt.—*Catalogue of Flower and Vegetable Seeds (illustrated).*

Webb & Sons, Wordsley, Stourbridge.—*Spring Catalogue for 1886 (illustrated with coloured plates).*

H. & F. Sharpe, Wisbech.—*Wholesale Catalogue of Garden and Agricultural Seeds.*

* * All correspondence should be directed either to "THE EDITOR" or to "THE PUBLISHER." Letters addressed to Dr. Hogg or members of the staff often remain unopened unavoidably. We request that no one will write privately to any of our correspondents, as doing so subjects them to unjustifiable trouble and expense.

Correspondents should not mix up on the same sheet questions relat-

ing to Gardening and those on Bee subjects, and should never send more than two or three questions at once. All articles intended for insertion should be written on one side of the paper only. We cannot reply to questions through the post, and we do not undertake to return rejected communications.

Books (Jackson).—A misprint of a figure occurred in our reply; however, if you had read the Journal as attentively as many do you would have found what you require in the same number on page 506.

Figure de Naples Pear (Somerset).—This Pear ripens in November, and is often very good indeed; it is described as follows in the "Fruit Manual":—"Fruit above medium size; oblong. Skin greenish yellow, entirely covered with thin delicate russet, and dark reddish brown on the side next the sun. Eye open, with very short segments, set in a wide shallow basin. Stalk three-quarters of an inch long, inserted without depression, frequently with a fleshy lip at the base. Flesh greenish white, buttery, and melting, with a rich sugary flavour. An excellent Pear; ripe in November. The tree is hardy and vigorous, and bears abundantly as a standard.

Dressing Vine Borders (Merchant).—By no means attempt to pick out the manure from the fibres or you will undo much of the good the mulching has done. Spread on 2 or 3 inches of good loam mixed with any wood ashes you may have, also lime rubbish, and if you can add a 6-inch potful of soot or bonemeal, or both, to each bushel of the compost it will be improved. On this spread a layer of manure; indeed, in that respect proceed exactly as you did last year. We are glad you have carried out our instructions so well, and the treatment has proved so satisfactory. The wood you have sent is very good indeed, and the abundance of fibrous roots is what we anticipated would be produced. Do not dig the borders nor let the roots get dry in summer, and you may expect a good crop of excellent Grapes. Your Vines are now in a healthy fruitful state, and we congratulate you on your good management.

Preparing Manure (A Very Old Subscriber).—It is seldom necessary to convey manure from stables to the site the hotbed is to occupy when that is near a residence. The manure can usually be prepared somewhere else, where it will not be offensive, and conveyed to the frame ground afterwards. When allowed to ferment in a heap in any convenient place, turned over four or five times, separating all adhering particles, and watering as may be needed for assisting fermentation, it is what is termed sweetened. It is when well prepared not offensive, but has a pungent and not a disagreeable smell that is not perceptible a short distance away. It is only in that condition that manure can be safely used. If offensive gases rise in a frame placed on a hotbed will destroy whatever plants, cuttings, or seedlings may be placed in the frame. It may be stated as a plain rule that if a candle will burn in a frame the air is safe for plants, but if the light is extinguished as soon as put in it is not safe, and more time must be allowed for the escape of deleterious gases and the consequent sweetening of the manure.

Hampstead Chrysanthemum Show (One of the Committee).—We are obliged by your letter, and assure you that if any omission occurred in inserting the fixture in our list it was not intentional. Schedules not infrequently arrive just a day too late for the dates of the shows to which they refer being inserted in the current issue, and between that and the issue following the exhibitions are over. We cannot positively say that this was so in the case of your schedule, because we have not a clear recollection whether it arrived with the tickets or not. We know the date of their receipt, and if the schedule came with them it was just too late for insertion in the published list. As to reporting, it is absolutely impossible that our representatives can attend all exhibitions. They travelled over a thousand miles during three weeks, and we think, therefore, did as much as could reasonably be expected. If you had sent a note of your show it would probably have been inserted. We have been told this week it was an excellent one, some of the groups splendid.

Cissus discolor, &c.—Grafting Apple and Plum Trees (A. G. F.).—The Cissus and other plants to which you refer in the first part of your letter are deciduous, and if you expect them to flower profusely they must be ripened until the whole of their foliage falls naturally. You can keep the Allamanda evergreen, but it will not rest so perfectly as if the foliage has been gradually and naturally ripened off. This should be done, for upon the ripened condition of the wood will entirely depend whether the plants make long or short growths before they flower after they are started again into growth. Cissus discolor will not lose the whole of its foliage during the winter—in fact, may be kept evergreen if deprived of rest to some extent. A shorter rest will suffice for this plant, and then it will not be so long without its beautiful foliage. We rest our plants as completely as possible through January, and then prune them, and they soon start vigorously into growth again, and by this practice this plant is not long deciduous. You could keep them evergreen if you could maintain a night temperature in your house of 60°. But if you do this do not expect your plants to flower as well as if ripened and rested. Plum and Apple trees should be grafted about the end of March, but this depends very much upon the season whether an early or late one.

Pruning Peach Trees (D. E.).—Judging by your letter your trees would be much benefited by being lifted and the roots placed in good loam, with a liberal quantity of lime rubbish and some wood ashes incorporated. They are growing too strongly, and the more severely you prune them the stronger they will grow if you let the roots alone. With strong roots forcing their way into the subsoil there is almost certain to be correspondingly strong growths essentially fruitless in character; but an abundance of small fibres near the surface of the border produce medium-sized wood that is certain to be fruitful if the shoots are so thinly disposed in summer that the leaves develop under the full influence of light and air, and are kept quite free from insects. We should dig up the trees at once carefully, see that the border is well drained, and place the roots in fresh soil, taking particular care that all of a fibrous nature are kept moist during the operation. A depth of 18 inches of soil will suffice, and this not being wet when used you may press down firmly. If you have a sufficient number of medium-sized hard brown shoots for covering the space between the main branches the "strong succulent growths" may be cut

entirely, and the shoots that issue from the base of these in spring be either rubbed out or pinched repeatedly in order to divert the sap where it may be required by other parts of the trees. Your aim should be to produce an equalisation of growth, and by timely disbudding so arrange the shoots in summer that there is no serious shading of the foliage by overcrowding. As a rule too many summer shoots are retained. Peach trees well managed in the growing season need little pruning when in a dormant state.

Eucharis amazonica (W. J. C.).—Judging from the leaves sent and the description of your plants, we are almost certain that they are attacked by the mite which has played such sad havoc amongst these plants during the past few years. Your plants will do no good until you succeed in eradicating this destructive pest. If you were to obtain clean stock, unless you destroyed all the plants you have and thoroughly cleaned the house, they would soon be as bad as those you have now. We advise you to keep them rather dry till the end of next month, and then turn them out of their pots and remove every particle of soil that has surrounded them to some distance and burn it. The drainage of the pots should be subjected to the same process. The pots should be cleaned by placing them in boiling water. We should cut away all the roots, and wash the bulbs in water as hot as it is possible to bear the hands in. After this, dip the bulbs in a strong solution of some insecticide, then repot them after they are dry, and be careful to use fresh pots. We should place them in another house as far from where they previously grew as possible. They would be all the better if you could plunge them in bottom heat to give them a start. We have never been troubled with this pest, but know that some cultivators have succeeded in stamping it out in the manner indicated, and we shall be glad to hear if you succeed in your object. The leaves sent of Clematis indivisa lobata appear as if they have been touched by frost. If you are certain this is not the case, examine the roots, and there we think you will discover the cause of your plant going off. Dryness will cause the leaves to go similar to those sent, also saturated soil. Wireworm in the soil will also cause this plant to fail. Some years ago we lost a fair-sized plant from this cause, and upon examination we found that the maggots had penetrated for a good distance the root portion of the stem.

Names of Fruits.—The names and addresses of senders of fruit to be named must in all cases be enclosed with the specimens, whether letters referring to the fruit are sent by post or not. The names are not necessarily required for publication, initials sufficing for that. (J. T. W.).—Beurre Diel.

Names of Plants.—We only undertake to name species of plants, not varieties that have originated from seed and termed florists' flowers. Flowering specimens are necessary of flowering plants, and Fern fronds should bear spores. Specimens should arrive in a fresh state in firm boxes. Slightly damp moss or soft green leaves form the best packing, dry cotton wool the worst. Not more than six specimens can be named at once. (W. B., Leicestershire).—Statice latifolia.

AGRICULTURAL PROGRESS.

LAYING down land in permanent pasture had brief notice in our first paper upon agricultural progress, but the subject is so important that we return to it now, hoping as we do that a more full, clear statement of how it is done and why it is worthy of more general attention may prove useful to

those of our readers to whom such hints are likely to make clear a part of farming that has so long been neglected and so little understood. To the home farmer the matter is one of especial importance, for in many an instance he is also the manager of an estate, and there are now few estates where some of the farms besides the home farm are not in hand. We know it is the boast of some agents that they have lost no tenants, but there are limits even to reductions of rent beyond which it is wrong to pass, and rather than make concessions which are positively ruinous to the landlord the land must be taken in hand and made the best of. A large area of land under corn cannot now be regarded as profitable, and we are bound to consider how we may economise labour and yet render the land fairly profitable.

Poor and foul is most of the land which comes to hand now. What shall we do with it? If we got fairly hold of it after Michaelmas—say by the middle of October—the drainage would have been seen to first of all, and then we should either ridge-plough it or break it up roughly with a steam cultivator, and so leave it till exposure to frost, wind, rain, and sunshine had brought it into condition for being cleaned and reduced to a fine tilth as early as possible in spring. A dressing of caustic lime is applied advantageously to almost all kinds of soil at any suitable time either in winter or spring before the preparation of the seed bed, but it is not absolutely indispensable. It will be apparent that cleaning of the soil and other preliminary work is neither elaborate nor expensive except when drainage has to be done. It is highly important, however, that the soil be rendered as free from foul weeds as possible, and be reduced to a fine tilth before sowing the seed.

Upon the selection and purity of the seed hangs success or failure. We require about 40 lbs. of seed to sow an acre of land. We may make the most careful selection of the best sorts mixed in due proportions, and send the order to a seedsman; yet we may not only fail to get what we require, but may have a large proportion of inferior seeds and chaff in the mixture. It is quite true that a few seedsmen supply pure and genuine Grass seeds, but it is equally true that very many do not do so, and the purchaser has to protect himself by buying his seed mixture for permanent pasture subject to botanical analysis. In the last annual report of the consulting botanist of the Royal Agricultural Society we find that one sample of Foxtail did not contain more than 2 per cent. of ripe seeds. One mixture consisted entirely of Rye Grass, with a little Trefoil and Clover, the Rye seed being infested with ergot; another mixture consisted of Rye Grass with only 1 per cent. of other Grasses and Clovers. Sixty-four per cent. of the samples of seed of Fiorin (*Agrostis alba, stolonifera*) were infested with ergot fungus, and 20 per cent. of the samples consisted of chaff up to half their bulk. These are some of the worst cases, and it was found that there was less adulteration generally than in former years. Yet the fact remains that adulteration is prevalent, and it is strongly recommended that the seeds should be procured separately and mixed at the farm, precisely in the same manner as we have been compelled to treat artificial manures. Considerable difference of opinion prevails as to the correct proportion of each sort of seed per acre. The fact that Cocksfoot is the most nutritious Grass, that it answers in all sorts of soil, taking so deep a hold of it as to suffer less from extremes of weather than any other Grass, affords the greatest bulk of hay and greatest amount of keep, and starts most quickly into growth after being cut, should be a strong inducement to use most of it, and we know instances where it has been used successfully with only a mixture of Clovers.

No doubt the seed of Rye Grass is used for adulteration because it is so cheap. It is undoubtedly good for alternate husbandry, but not for permanent pasture. Fiorin should be altogether discarded owing to the certainty of ergot being brought into the pasture by it, and ergot is undoubtedly a fertile source of abortion, not only among ewes but among hay-fed cows. It is quite possible that when abortion spreads

through a herd and is regarded as a dreadful mystery or an infectious disorder that it may be owing solely to ergot in the hay consumed by the cows—*ergo*, never sow Fiorin, and although the seedsmen now recommend it, they will soon discard it from their catalogues when it proves unsaleable. Without assuming to be able to offer the very best selection of seeds for permanent pasture, we may safely enumerate one that has given us satisfaction—14 lbs. Cocksfoot, 6 lbs. each of Foxtail and Meadow Fescue, 3 lbs. each of Timothy and Tall Fescue, and 1 lb. each of Hard Fescue, Sheep's Fescue, Yarrow, Rough Meadow Grass, Crested Dogtail, Perennial Red Clover, Cow Grass, Dutch Clover, and Alsike. This quantity of seed is sufficient for an acre of land, and if the seed is only genuine and the culture good there need be very little doubt of a successful result. The mere sowing of the seed is insufficient to insure good pasture, and we hope to continue this important subject next week.

WORK ON THE HOME FARM.

Why should pigs be kept in stys reeking with filth? That the risk of loss from doing so is considerable has recently been made clear by the spread of a contagious disease among herds of pigs on so many farms that the markets were closed against store pigs for several weeks, and severe losses were incurred by many farmers. Well will it be if such losses lead to pigs being kept in greater comfort and cleanliness. Let the stys have clean dry litter daily; see that the drainage from sty and yard is open and thorough; keep the entire surface of walls and fences clean and sweet with frequent lime-washings; let the diet consist of nourishing wholesome food, avoid the use of garbage and filth, and mix common salt with the food frequently. Cattle Cabbage and roots make a wholesome change in the diet. Keep all purchased pigs in a separate yard for a few weeks in order to avoid all risk of infection. We have reason to believe that by the exercise of due care and attention to such details pigs may be kept in a healthy and thriving condition; without such care they are unsafe. No doubt the fact that pigs are so frequently kept in a filthy condition with impunity apparently renders such advice unnecessary, but knowing as we do how heavy the loss is when a diseased herd has to be slaughtered and buried, we are bound to warn our readers to be on their guard and to adopt measures of precaution in time.

Especially care is now taken to keep the breeding flocks safe from all disturbance or excitement. Shepherds must be on the alert to protect them from straying dogs or the incursions of hounds. Much harm is often done by horses and hounds out hunting at this season of the year, and while by no means wishing to decry fox-hunting, we deplore the mischief so often done through thoughtlessness. Abortion is unquestionably often traceable to fright arising from some such cause. See, too, that the ewes are not kept in muddy folds, nor must they have many Turnips before lambing. It is only by frequent repetition that we dare hope to do good by such advice. Care and painstaking lead to success as surely as does negligence to failure, and it is, alas! by negligence in trifles that our work is so often rendered futile. Let no implements, tools, carts, or waggons be left on the land, or at all exposed to weather after they have been used, but make it a fixed rule always to have them put under shelter, clear, and in good order. We recently found a waggon that had been left out in the rain, in the bottom of which there was an inch of water left to soak slowly into the boards. Rust and decay are always at work through some such cause. Take advantage of wet weather to examine all the tools of the farm, and have them repainted and put into thorough repair in readiness for next season.

REMARKS.

13th.—Much warmer, dull, and rather damp.
14th.—Fair, with very slight fog.
15th.—Foggy till 10 A.M., then bright and pleasant; clear cold night.
16th.—Fine bright day.
17th.—Dull and damp.
18th.—Damp and foggy.
19th.—Rather drier.

A dull week, with very high barometer; temperature above the average and very uniform; and very little rain.—G. J. SYMONS.

CHOICE WINTER FLOWERS.

THERE are plenty of choice winter-flowering plants—so many, in fact, that it is difficult to make a selection. It may not, however, be unseasonable to call attention to a few of the most worthy, and I will take the old Double White Camellia as fitting for a first place—a plant long known in gardens and everywhere admired. The wax-like flowers may be twisted from their place without a particle of wood attached, mounted on wire stems, and finally become a centrepiece in some choice bouquet or other floral arrangement, lasting fresh longer than many flowers which are cut with woody stems. That they may last as long as possible I use two and sometimes three wires to pierce the bloom, depending on its size, bending the ends downwards, and so form a stem by binding with a small piece of wire previous to closing in the stem, arranging a pinch of fresh green moss immediately under the calyx, by which means the flowers will retain all their original freshness, especially if placed for a short time in water up to this point, and so you may continue till the whole of the season's blooms have been utilised without the loss of wood. This is a great gain, for between the flower buds the growth bud for next year is already prominent, and to lose these first buds simply means to throw the plant the following year much later in flowering, since the ensuing year's bloom is dependent on axillary instead of terminal buds. Those nurserymen who possess very fine specimens secure annually without fail a good Christmas supply of these flowers, and I know some plants which carry 2000 blooms annually, from which not a particle of wood is detached except by accident. Unlike many midwinter flowers the Camellia will not endure forcing into bloom. The time to force it is in its growing season, and that not to an extent generally understood by the term. Encourage them to make an early growth and mature the wood as early as possible. Setting the buds will follow if all be well, and in reality the "winter" forcing has been done in spring. Besides the old Double White Camellia there are other excellent whites of fine form and substance, which must not be passed unnoticed. Among these are *C. fimbriata*, *candidissima*, *Mathottiana alba*, of fine form, pure in its whiteness, and massive in its bearing. Pearl is one of exquisite form and beautifully cupped; Montironi is also very pure white, and the same may be said of The Bride. Among deep-coloured and showy varieties Donkelaari, Chandleri, Mathottiana, Monarch, Bealii, Imbricata, and Reine des Fleurs stand out among the best. Then we have a superbly beautiful flower in Lady Hume's Blush, well known to all; and yet another, not so well known perhaps, is found in the semi-double *reticulata*, of which a magnificent specimen may be found in the Botanical Gardens, Birmingham, laden annually with very large flowers of a rosy lake colour.

Bouvardias are of considerable importance, and year by year are gaining public favour, for no matter whether in buttonhole or spray, bouquet or vase, Bouvardias are sure to be prized, not more, perhaps, for their chaste and elegant

appearance than for their delicious fragrance—a fragrance not overpowering, but sufficient to please and to be welcomed by all comers. The culture of the Bouvardia has during the past few years been greatly simplified, and the genus has been enriched by many fine additions, including some excellent double scarlet varieties. Bouvardias, whether they have been grown in pots or the open ground, should now be accommodated with a temperature of from 55° to 65°, with a proportionate rise by sun heat, but which we get little of at this season. Plants which have been thoroughly ripened during the growing season will not fail to produce in great profusion their exceedingly useful flowers, especially if assisted with artificial manure. About one-half of a teaspoonful of any approved fertiliser to a plant in a 48-sized pot once a week is good, and I prefer using them after giving water, as they are not then so liable to be washed out of the pots as when applied immediately before watering.

The Epiphyllums are attractive and highly interesting plants for many purposes, but still seem generally overlooked. I do not regard them in the light of useful flowers for bouquet, buttonhole, or spray use, since their somewhat quaint forms do not adapt them specially for such use. Still they possess qualities which place them among the most valuable of winter flowers. As basket plants for the warm conservatory they are especially useful just now, their naturally pendant habit of growth admirably adapting them for this purpose, and being so distinct from all other winter flowers would seem to claim for them a position from which they are now almost excluded. The present is a good time to secure the plants and make a start. In some establishments there are varieties which seldom flower; these should be cut down to the point at which they commence branching, obtaining some pieces of any of the better forms of *E. truncatum* to graft on the branches of the old trunks, and by the ensuing year a fine specimen will be obtained. The grafting is very simple, as the stock and scion quickly unite. Simply split the growth of the stock asunder, and with a sharp knife push back the bark of the scion on either side, inserting this in the usual way, securing it either by tying or with the sharp spines of the *Pereskia*. *Pereskia aculeata* makes the best stock, and those required for baskets should be stout and firm, not more than a foot high at the graft. A greenhouse temperature suits them well, and a comparatively dry atmosphere. In summer a cold frame will be found the best place for them, or a cool house where abundance of air may be admitted. The soil should consist of strong fibrous loam, to which is added one-third its quantity of lumpy peat and a similar proportion of old mortar rubbish, with little well-decayed leaf soil and silver sand. Very little water is needed, for they do not root so vigorously as some, but when growing they will be benefited by an occasional syringing. Much the best collection of these plants, either as regard numbers or varieties, which I have met were grown some twelve years since in the Exotic Nurseries at Tooting. Speaking from memory I am of opinion that there were fifty varieties of *E. truncatum*, which every season made a grand show. A few of the best are *album violaceum*, *Ruckerianum* and the variety *rubrum*, *Russellianum superbum*, *violaceum grandiflorum* and *violaceum superbum*, *Salmonianum rubrum*, and *grandiflorum marginatum*, with *spectabile* and its forms.

Euphorbia fulgens at this season is one of the brightest occupants of the stove, excelling even the Bouvardia for brilliancy. The flowers, produced in wreath-like racemes, are at once ready for use, and its pleasing glaucous leaves, sometimes accompanied by a tinge of bronze, seem to harmonise more favourably with it than even Maidenhair Fern. It is a lovely plant, and where planted out and trained to the roof near the glass it flowers with remarkable freedom. Even after the main racemes have been removed it produces laterals freely, and these, though small, are very welcome. Be careful not to give this plant too much water, and provide thorough drainage.

We find an attractive plant in *Linum trigynum*, the East Indies Flax, which grows 2 feet high, and produces its golden yellow blossoms in great profusion. It is very pleasing when associated with other plants in the warm conservatory. The individual flowers do not last long, but as they are continuously produced plants may be had in flower for several months.

What are more popular at this season of the year than the flowers of the Christmas Rose? which, when protected by glass, become pure white, and hence of great value. From early in November, depending on the season to a great extent, flowers of this perennial may be had naturally in the open ground, the only protection needed being an old light or frame. For church decoration they are greatly in demand, owing probably to the association of its appropriate English name with this great festive season. None of the species or varieties is so useful for this purpose as *Helleborus niger* and the variety *major*. Very old inhabitants of our gardens these, which caused them to be used in former days ere glass structures were in vogue, and the valuable winter flowers we now have were unknown. This Christmas Rose must not be trifled with, as it is impatient of removal, and though annually thousands of its roots reach this country, still it is no more plentiful, and good clumps are quite a rarity. It cannot endure being lifted and potted, and after flowering transplanted again; for if this is repeated a few times it will do so at the cost of your plants. Rather plant them in beds permanently, and in such a way that some spare lights at liberty in autumn and winter may cover them. Place these on early in November, and there will be no occasion to disturb a plant.

Then we have late *Chrysanthemums* in plenty now, and what more welcome than their snowy blossoms? and year by year we are learning some new hint in their culture and how best to have them for Christmas and the New Year. There are plenty this season, at least more plentiful than last year; and some of the most valuable late whites are *Boule de Neige*, a snowy white reflexed variety of dwarf habit, and very free, little known yet. It has received its due reward, and been honoured with two certificates. Better known whites are *Princess Teck*, *Fair Maid of Guernsey*, *Ethel*, *Virginalis*, *Sarnia*, white delicately shaded flesh; and *Meg Merilees* are the best varieties for Christmas.

The *Poinsettia* must be included, for the whorl of coloured bracts is more than a substitute for flowers. For association with fine-foliage plants in the warm greenhouse or stove we have nothing at this season which can compare with them in brilliancy, and they may be had in all sizes, from 6 inches high to 6 feet.

Welcome, too, is the *Æthiopian* or *Nile Lily*, *Richardia æthiopica*, of which the pure white spathes render it at this season unique. It is too well known to need further commendation. The queenly *Lily of the Amazon*, *Eucharis amazonica*, is doubly welcome now. Then we have the fragrant *White Roman Hyacinths*, valuable for many purposes. These, if brought on gradually and introduced into heat as required, will last for a long time. I have already forced several hundreds, and as soon as the first or second flowers expand I move them to cooler quarters, where they grow sturdily. Nor must the *Lily of the Valley*, so graceful and sweet, be omitted. The ease with which this is forced in winter renders it of the greatest value, for it is sure to gain many admirers, and always commands a speedy sale. Other valuable plants are the *Cyclamens*, telling in any arrangement. Whether required for the flowers alone, or as pot plants for general decorative purposes, they are always prized. Many fine strains are now in commerce. How light and graceful for conservatory decoration, or grouping generally, are the *White Paris Daisies*, or *Marguerites*, at this season! Plants specially grown during summer—that is, cuttings inserted early in June—when rooted and potted, stopped once or twice during the season to make them bushy, will grow into fine plants and flower for at least three months

in the dullest part of winter. For this purpose nothing can equal that variety of *Chrysanthemum frutescens* known as *Madame Farfoulin*. This surpasses all the varieties as a midwinter flower and as a free and abundant bloomer. Ladies are particularly fond of it, choosing it frequently in preference to other flowers for sprays for the ballroom, where it is invariably admired.

Favourite flowers are *Tree Carnations*, in which case the brilliant scarlets seem to be more eagerly sought after than any other colour. Impatient of any approach to a close atmosphere, especially when accompanied by artificial heat, they should always occupy a light airy position. Free ventilation is essential to their well-being, for if the reverse they soon become sickly and weak. Green fly quickly infests them. A little fumigating with tobacco paper, however, will disperse the latter. The winter-flowering *Begonias* must not be overlooked while we have such fine decorative forms as *insignis*, *nitida*, *suavis*, and others. Very pretty and effective are these delicately coloured flowers, so pleasing for association with other plants. Then we have miscellaneous plants, such as *Habrothamnus*, single and double *Primulas*, *Zonal Pelargoniums* in variety, *Azaleas*, *Francoa ramosa*, *Lapagerias*, *Heliotropes*, the ever welcome and fragrant *Mignonette*, *Heather*, and *Epacris*; nor would I omit the lovely blue of *Agatheæ celestis* and *Hovea Celsi*. The former we frequently meet, but how seldom the latter or any of the other species of its genus. We also have the *Indian Daphnes* and *Jasmines*, such as *hirsutum*, *grandiflorum*, *gracillimum*, and others. These and many more all assist in making the winter gay with attractive flowers. In the foregoing remarks I have not given anything approaching a complete list of winter flowers—far from it, many more remain, sweet and pretty, as, for instance, the *Winter Heliotrope*, *Tussilago fragrans*, which, though a pest in many parts, is a charming plant in pots; and so on, in like manner, might others, somewhat neglected and common though they be, lend additional charms if only a little attention was bestowed upon them.—J. H. E.

GROS COLMAN VINE.

TILL within the past two years I have had little personal acquaintance with this Grape, and even now my experience is not extensive. But I have seen sufficient to convince me that in several respects it differs from every other Grape.

It is said that the Vine will not bear the sun so well as other varieties, and it has been recommended that when there is a choice it should be planted on the side of the house where there is the least sunlight. To this I have to say that I am now located in one of the warmest spots in England, and have the management of vineries which possibly admit a greater amount of light than any others in the country (the panes of glass in our new vinery are 37 by 20 inches, and the rafters are comparatively slight) yet *Gros Colman*, other conditions being suitable, is no more disposed to burn than any other variety. That its foliage gets discoloured and even shrivelled up early in the season in some situations I am bound to admit. The question then comes, What is the cause of this, and how can it be prevented? I will relate a little experience which bears on the matter.

Some Vines of several varieties were grown from eyes. Part of their number was planted out, the rest being shifted as they required it and grown as pot Vines in precisely similar soil. This was composed of turf cut about 2 to 2½ inches thick, with a liberal supply of old mortar and half-inch bones. As might be expected, under good treatment they soon made fine canes with short joints, and moderate, inclined to large leaves, and all went on apparently well till they had grown to their allotted length, and some of them actually began to ripen, when there were certain peculiarities in their behaviour which claimed attention. They looked at times as if they had been in company with a *Sensitive Plant*, and were trying to imitate its eccentricities. On a hot day more especially the leafstalks, instead of standing out at right angles to the stem, would turn backwards some couple of inches or more, as if they were drooping, though the leaves would remain rigid. They generally partially or wholly regained their proper position during the night. It was most marked with the Vines in the pots for a time, but afterwards those in the borders were affected in a like manner.

By-and-by matters assumed a more serious aspect. The foliage

of some of them began to dry up in patches, and there was a danger of the ripening being interfered with. Happily the one in charge was a patient learner and did not lose his head over the matter, but it made him feel uncomfortable. The pot Vines by this time had filled the pots with roots, and it was thought advisable, as the small quantity of compost must be partially exhausted, to give them a little help in the shape of liquid manure. The effect was very soon apparent. In less than twelve hours the leafstalks had altered their positions, but they fell again and again at intervals during the next two or three weeks, after which time they remained permanently in their proper form.

But could it be possible that the newly-formed borders 5½ feet wide and 2½ deep should require assistance also before they were twelve months old? Such was the case undoubtedly, for though they held out longer than the pots, the Vines there exhibited the same symptoms, and the same treatment cured them.

Afterwards it was observed that the leaves, though apparently good were thin, and when the feeding had been continued some little time, the leaves thickened considerably, some of them forming warty excrescences. With the exception of one or two of the pot Vines they all finished off very well, and such canes were matured as most people would be satisfied with. The exceptions were of the variety under notice, and every plant of this variety suffered more than did any other sort.

So much for the facts, now for the theory. I believe the soil used to be singularly deficient in potash, at least in an assimilable form, for whenever a manure has been applied which was rich in that element the effect has been most marked. On the other hand, according to such experiments as have been made, the addition of bones to the soil is not attended with any good result. I take it that the *debris* from the native rocks which contain an abundance of fossils provide a good supply of phosphate. The land is said to be hungry, and certain it is that for farming purposes it swallows as much manure as would poison a good fertile soil. As is very often the case, I believe the difference between fertility and sterility is simply an insufficient supply of one element, which a person with a rudimentary knowledge of chemistry could supply at a trifling cost.

Gros Colman according to my experience cannot flourish without an abundance of potash. Most soils doubtless contain a sufficiency at first, but it needs replenishing before Vines have been grown in it a great length of time.—W.M. TAYLOR.

USEFUL TURNIPS.

THE season of 1885 has not been one of the most favourable for the Turnip crop, especially on dry hot soils. With us Turnips have been so far plentiful, but not of the best quality. Our first sowing is made towards the end of February if the weather is favourable, the varieties being Early Milan and Sutton's Snowball. The former one we do not intend growing again, as its quality is not good enough on our soil, and as the latter, not being many days behind it, makes it really worth waiting for. Hereabouts Snowball is the only variety grown for all seasons, but I am not inclined to think it so good for late autumn and winter as Veitch's Red Globe and Chirk Castle Blackstone varieties. Red Globe we have had in splendid condition since September; in fact, this has proved itself the best flavoured this year so far. Chirk Castle is the variety we depend upon for late winter and spring, being very hardy and of fine quality. For exhibition, Sutton's Snowball is hardly to be surpassed, being of good shape and pure in colour.

Those who have a breadth of good Turnips to come in later on will, I think, be very fortunate, for in many districts this crop is very backward, owing to the most unfavourable state of the ground at the time of sowing. Field crops, too, are much in the same state of backwardness. Small sowings only are made in early spring, as a large percentage often run to seed. An east border is the site selected for early crops, and a north aspect we find the best suited for summer, being less exposed to hot sun.

For Turnips we give a fairly liberal dressing of manure either from the stables or cowyard; the latter is preferred for light soils, the former for heavy and close ground. It often happens that the gardener has no choice in this matter, having to use what he can get. Such is the case with us, as nothing but horse manure comes within our reach, although the ground sadly requires a change, and I have known instances when the opposite is the case respecting the kind of manure at hand.

It is a good plan to dust frequently with soot and wood ashes at the early stages of growth, as this tends to promote a quick development of leaves, and also helps to check the ravages of the much-dreaded Turnip fly. To have good Turnips this is often considered to be absolutely necessary, as if growth is slow they

are apt to become stringy and of no use but for flavouring purposes. The practice of sowing broadcast is not so generally practised as formerly, for when grown in this way there is greater difficulty in keeping them free from weeds than when sown in drills. There are many varieties of Turnips enumerated in catalogues, perhaps too many, but I think those mentioned in this note will be found sufficient in number for small gardens, and, indeed, in larger ones too. Most gardeners have their favourite varieties of vegetables, and Turnips are no exception to the rule, yet I doubt if there are three better or more reliable sorts grown than Snowball, Red Globe, and Chirk Castle for all-round purposes.—S. B.

THE PRIMULAS.

(Continued from page 539.)

P. MAGELLANICA, *Lehm.*—A splendid figure of this is given in Hooker's "Antarctic Flora," tab. 120. It is by many considered only an extreme form of *P. farinosa*, and so it may be in a wide sense. In "De Candolle's Prod." it is, however, thought worthy of a specific rank, as it is also on the Continent generally, and, indeed, when seen under cultivation it appears too distinct and well marked to be placed under *P. farinosa*. Where the latter will grow *P. magellanica* will be found to grow also. It likes a slightly drier soil, however, which is easily managed by raising a small mound. A mixture of peat and sand, or a place in the bog bed, as described above, suits it. It will be found all the better for protection during severe weather, which we manage with small squares of glass. It ripens seed well, by which means it is readily increased. It differs from *farinosa* chiefly in the shorter flower stalks or peduncles, in the position of the stamens in the tube of the corolla, and also in the colour of the flowers, they being white or very pale purple. It differs altogether in habit, much stouter, larger leaves, and longer scapes. These characters, as far as we have observed, are constant. It flowers with us a little earlier than *P. farinosa*. Mr. Darwin found it in the Magellan Straits.

P. MARGINATA, *Curt.* (the Silvery-edged Primrose).—We are so much in the habit of considering this plant distinct from all others in the genus, that the letterpress accompanying the figure on page 191 of the "Botanical Magazine," published May 1st, 1792, may not be without interest. The author above quoted says:—"There is no difficulty in determining the British plants of this genus, but much in ascertaining many of the foreign ones. Professor Jacquin has taken great pains to elucidate them in his 'Miscel. Austr.,' where fifteen are specifically described, none of which accord exactly with the plant here figured (*i.e.*, *P. marginata*), which has every appearance of being a distinct species. In the 'Hortus Kewensis' it is described as the *P. glutinosa* of the 'Flora Austriaca,' with which it agrees in many respects; but specimens sent from Vienna show it to be a different plant. In its farinaceous tendency it accords with the *Primula Auricula*, but is very unlike that plant as it is figured in its wild state by Professor Jacquin in the 'Flora Austriaca,' the leaves being much narrower, the flowers larger, and of adifferent colour. It differs from *P. glutinosa* in the shortness of its involucre, from *P. villosa* in having leaves much narrower, perfectly smooth in respect to villi, and in the colour of its blossoms, which approach that of the Lilac, but more especially in its disposition to become mealy, particularly on the edges of its leaves between the serratures, where it is so strong as to make the leaf appear with a white or silvery edge. As this character is so constant to it, and not to any other species of *Primula* that we are acquainted with, we have given to it the name of *marginata*." As we know this plant at the present time, even from newly imported specimens, it approaches no other near enough for a comparison. It has a distinctly shrubby habit, which we do not find equalled by any other European Primrose. *P. viscosa* and its numerous forms have a shrubby tendency, but they are far from being marked in this way, while *P. marginata* has usually from ten to a dozen bare stems, reminding one in winter of a miniature stunted Stone Pine. The leaves with us are always thickly covered with farina, which seems to have become hardened at the margins, and looks like enamel. They are oval or oblong, in type specimens, the serratures are small and numerous, while in cultivated forms, and especially in that called *cœrulea*, they are much larger, more irregular, and often double. The blade narrows gradually to the base, serratures more or less all the way, where it again dilates or suddenly broadens at the clasping point. The flower stalk is from 1 to 5 or 6 inches high, carrying an umbel of from three to a dozen or more large clear lilac, blue, or purplish flowers, varying in the varieties. Those which have received names are *cœrulea*, *densiflora*, *grandiflora*, &c. On the rockery, where it can get sufficient time, this is one of the easiest Primroses to grow, almost perpendicular positions being apparently the place where it does best. It requires, however, plenty of water during the growing season,

It flowers from February to April. It grows readily from cuttings, by which means it may be increased, or by seed, which it ripens fairly well.

Introduced about 1781 by Mr. Lee of Hammersmith. Native of the Alps of Dauphiny. Syn. *P. crenata*, Lam.

P. MINIMA, L.—Apart from the various forms or hybrids to which it has helped to give rise, this is the only *Primula* belonging to the section *Kablikia*, *Opiz.*, or *Chamaecallis*, *Schott.* It has to do with something over a dozen hybrids—in some predominating, in others hardly traceable, unless in the size and shape of the flowers. Among them may be mentioned *P. salisburyensis*, *P. pumila*, *P. Flörkeana*, *P. Huteri*, *P. Steini*, *P. Forsteri*, *P. Weldeniana*, *P. biflora*, &c., all of them varying more or less from the type, and all worthy a select place on the rockery. Next to our own native species, *P. minima* is amongst the best known in gardens of all the European kinds, and perhaps the easiest to keep when once fairly started. In one or two of the old gardens we have seen large pieces of it in excellent health—in one particularly, amongst which were some bulbs quite at home, and apparently not at all disagreeing with the Primrose. The position was fully exposed, a few small stones dotted here and there among the plants, the soil, I believe, being taken from the ordinary garden border. The above is an instance of how this *Primula* will grow in the north, no trouble being attached to its cultivation at all compared with what we in the south have to get it even to grow at all without particular attention. During the months of May and June no sight could be prettier than a well-flowered clump of this alpine gem, the flowers practically covering the leaves, so thickly do they come from the little jagged rosettes. It has already been pointed out that most *Primulas* confine themselves either to the granite or calcareous regions. *P. minima* is, however, an exception; one collector finds it plentifully in one region, while another is just as successful in the other. In a wild state it varies very little, unless in height. It is, however, occasionally found with white flowers, and sometimes with two on a stem. It grows in little tufts from 1 to 2 or 3 inches high, forming compact little masses, the small cuneate leaves, deeply and sharply toothed at the apex only, forming little rosettes, attractive when open. The flower stalks almost sessile, rosy pink with a white silvery eye, and almost an inch in diameter. At present we have it doing well in pots firmly wedged between small pieces of tufa. It is increasing rapidly, and will soon cover the pot. We are convinced that the only road to success with this plant is a western exposure in a shallow and well-drained soil. It was introduced by Mr. Schleicher of Bex in 1818, and also by the Horticultural Society. Native habitats: On the highest mountains of Southern Europe, almost to the limits of perpetual snow, 7000 to 8000 feet elevation; calcareous Alps of Eastern Switzerland, 4000 to 8500 feet above sea level, &c. *P. serratifolia*, *Gussmus*, is a variety with more dentate leaves and nearly allied to *P. Sauteri*, also a variety.

P. MINUTISSIMA, *Jacquemont*.—A very small densely tufted stoloniferous species, mentioned in connection with *P. Hydei*, of which it is sometimes considered a variety. As we know the plant, however, it is much smaller in all its parts. Leaves less divided, and slightly mealy underneath. It seems perfectly hardy in the open air in pots; we have not yet tried it planted out. The surface of the pot is covered with small pieces of soft sandstone, the stolons running freely over them, attaching themselves by their tiny wiry roots. For this reason it should never be allowed to become dry, and a shady corner is preferred as being more retentive of moisture in such a position. It may be increased by taking these stolons off in spring and potting them singly. The whole plant, including the flower spike, is not more than an inch high; the leaves, formed in little rosettes, are spatulate, lanceolate, often pointed or obtuse, and irregularly toothed. The scape one to three-flowered, small, but bright rose-coloured. It flowers June to August. Native of Alpine Himalayas at 12,000 to 16,000 feet above sea level, and from Kashmir to Kumaon at 12,000 to 15,000 feet. Syn., *P. Saundersiana*, *Royle*; = *Stracheyi*, *Hk. fil.* Var. *P. spathulata* has larger leaves and much larger flowers. Sikkim.

P. MISTASSINICA, *Michx.*—The lesser American Bird's-eye Primrose derives its name, it is said, from its early appearance in spring. It is nearly allied to *P. farinosa*, and with that species forms the only wild representatives of the genus in the northern United States. It grows from 2 to 6 inches high, having numerous spatulate or wedge-oblong leaves, not distinctly veined, and devoid of farinose, which is one of the characteristics of the other, the broad part of the blade irregularly toothed from the middle to the apex. The flower scapes are sparingly mealy, carrying from one to eight flowers in loose umbel. Flowers half an inch in diameter when strong, flesh-coloured, the lobes of the corolla deeply embeccate. Calyx composed of five blunt sepals, each having about the same number of prominent ribs, and can be grown in the same

compost as *P. farinosa*, preferring a shady to a sunny position. It dies down in the same way as that species during winter, and protection from birds, &c., is of equal necessity. It was collected by Mr. Drummond and Dr. Richardson while engaged on the second Arctic expedition. It flowered with us about the middle of April, but generally early in May. Willoughby Mountain, the Upper Lakes, &c.

P. pusilla, *Goldie*, in "Edin. Phil. Jour.," p. 322, t. 11. = *P. farinosa*, *Nutt.*—D.

(To be continued.)

THE PEAR CONFERENCE.

I SEE there are some complaints respecting this, but some of them were rather premature, and altogether I think exhibitors have reason to feel satisfied with the result. The whole of the exhibitors from South Wales had a corrected list of names sent to them through the post, and in this way the main object of the Conference was fully accomplished. This has given complete satisfaction, and now I know of more than either one or two growers who are sorry they did not avail themselves of such an excellent opportunity of verifying or correcting the nomenclature of their fruit. This often happens in cases of the kind, but there is no reason it should do so, as anything which is submitted to the hands of the Royal Horticultural Society goes to a safe and impartial tribunal.—J. MUIR, *Margam Park, S. Wales.*

PLANTS CERTIFICATED IN 1885.

MESSRS J. VEITCH & SONS.

MANY novelties annually make their appearance in the well-known Chelsea Nurseries, both introductions and home-raised varieties or hybrids; and this year has been particularly prolific, for no less than sixty plants shown by Messrs. J. Veitch & Sons have been honoured with certificates. In so large a number it might be readily imagined that much diversity would be found, and this is the case; but still we find certain specialties taking the lead, as for instance Orchids, Amaryllises, and Rhododendrons, which are so extensively and well grown in the nursery named. A few notes on the principal novelties, the merits of which have been recognised by the Floral Committee and judges, may be useful now that many persons are thinking of adding some to their collections.

The first place may be suitably accorded to the Orchids, which comprise *Cattleya autumnalis*, *Cypripedium macropterum*, *C. Sedeni candidibulum*, *Dendrobium endocharis*, *Lælia Canhamiana*, *Masdevallia Gairiana*, and *Thunia Veitchiana*, while to these must be added *Cypripedium Godefroyæ* since it was announced with illustration in the spring catalogue for 1884 of this firm, though shown in flower by the two celebrated amateurs W. Lee, Esq., and Baron Schröder, to whom certificates were awarded. The three Ladies' Slippers named are very distinct. *C. macropterum* is a hybrid between *C. Lowi* and *C. superbians*, and curiously intermediate in characters. *C. Sedeni candidibulum* is one of the *C. longifolium* class crossed with *C. Schlumii alium*, and while resembling *C. Sedeni* in form and habit it is much lighter in colour, so much in fact that some have designated it a "White *Sedeni*." *C. Godefroyæ* is a grand addition to the genus, and though as yet commanding a good price it will undoubtedly become one of the greatest favourites. In the form of the flowers it is somewhat like *C. concolor* and *C. niveni*, but it especially resembles the latter in the white or creamy ground colour. It is, however, more beautiful, the flowers being densely spotted with rich purplish crimson. The leaves are also prettily mottled, and the plant appears to be free-flowering. The habit and form of the flowers are admirably represented in the woodcut (fig. 85) for which we are indebted to Messrs. Veitch & Sons. The other certificated Orchids were described last week, except *Lælia Canhamiana* and *Cattleya autumnalis*, the former being a beautiful hybrid between *C. Mossiæ* and *Lælia purpurata*, with large richly coloured flowers, and the other is small-flowered *Cattleya* of pleasing colour, the crimson lip having a fine white throat and contrasting well with crimson purple sepals and petals.

The present is not the best time for seeing the attractions of Orchids, and unfortunately the three or four days' heavy fogs experienced recently have seriously affected many that were in flower, yet Messrs. Veitch have still in their houses a pleasing display and abundant promise of a finer one later on. The *Odontoglossums* of the *O. Alexandræ*, *O. Pescatorei*, and *O. Andersonianum* types are bearing scores of flowers of good varieties, while the bright little *Sopronitis grandiflora* imparts a most welcome colouring suspended from the roof. *Cypripediums*, including the form of *Sedeni* already mentioned, the useful and handsome *C. Leeanum superbum*, *C. niveum*, *C. marmorophyllum*, and *C. reticulatum*, are also flowering freely. The last named is an interesting species of the *C. longifolium* section with pale green flowers faintly veined with a darker shade, and having the petals narrow, tapering, and twisted corkscrew fashion. It will probably prove the progenitor of some distinct hybrids. Of *Dendrobiums* *D. Wardianum* is attractive in several houses, and some very distinct varieties are included in the collection. *Calanthes* are abundant, but the fogs have somewhat affected the colour of *C. Veitchi* and other bright-coloured forms. *Phalaenopses* are showing flower buds in hundreds, and with favourable weather will shortly provide a grand show.

Nine *Amaryllises* have been certificated, but it is unnecessary to refer to them individually, for the general character of the Chelsea varieties is

now well known. So great an advance has been made that it is surprising new forms can still be obtained surpassing in some points those previously raised. By exercising extreme care and forethought in the crossings, however, it is evident that the capacity for improvement in the *Amaryllis* is by no means exhausted, and every season we confidently look for some new break amongst the innumerable seedlings raised. In form and size it does not seem possible to make any further advance, but the colours are being enriched and diversified, and by crossing with *A. reticulata*,

is said to have been one of the parents, but its influence is scarcely perceptible. There are now several of these and other varieties in flower at Chelsea, and quite recently the handsome double forms were very attractive.

It would be unnecessary to refer to all the miscellaneous plants which have been certificated, but prominent amongst those of sterling merit is *Amasonia punicea*, which has been repeatedly noted as a useful addition to our flowering stove plants. It is easily grown, readily propagated, and

Fig. 85.—*CYPRIPEDIUM GODEFROYE*.

a group is being formed which greatly extends the flowering season of these noble plants.

Rhododendrons of the greenhouse hybrid class are still commanding the attention they deserve as useful and beautiful flowering plants. The introductions and hybrids which have been placed in cultivation from the Chelsea Nursery are very numerous, and this year they have been increased by ten more, which comprise some of the best that have yet been obtained. The scarlet forms are *Apollo*, *Cardinale*, and *Militaire*, all different shades, with large blooms on compact heads. *Indian Yellow*, *Minerva*, and *Teysmanni* are yellow-flowered varieties; most welcome additions to the list. *Incarnatum floribundum* has buff and rose-tinted flowers, and *Cartisi* is brilliant crimson. *Pearl*, white and rose-tinted, and *Manglesi*, white with purple dots, are hybrids in which *R. Aucklandi*

lasts in good condition for so long a time that it cannot be too highly commended. It is, moreover, very distinct in appearance, the bright red bracts with yellowish flowers thickly clothing the gracefully arching branches. A very bold and imposing Fern is *Cyathea divergens* with its large drooping bipinnate fronds, and another good distinct Fern is *Davallia retusa*, which is capitally suited for baskets, the fronds being sometimes over a yard in length, with angular pinnules somewhat like *Adiantum trapeziforme*. *Lomariopsis buxifolia* is also a distinct and pretty Fern, which is of a climbing habit, and is seen to great advantage when clinging to the stem of a Tree Fern. The specific name refers to the pinnules, which bear some resemblance in form and colour to the leaves of the Box. *Nepenthes cincta* is a fine Pitcher Plant of interesting origin, the seeds having been imported with those of *N. Northiana*, but it is believed to be

a natural hybrid between that species and *N. albo-marginata*. It is of strong habit and bears leaves 18 inches to 2 feet in length, with pitchers 10 inches long, of a deep red colour, with darker spots and blotches. Tuberous Begonias have now become very numerous, and it is not easy to obtain new types amongst them. This is, however, being effected by crosses with *B. socotrana*, which was introduced from Socotra a year or two since. One of these hybrids, named John Heal, has been certificated, and gives much promise of being a useful Begonia, especially as its rich rosy flowers last a great time, either on the plant or cut and placed in water. Others, of a similar character as regards habit, have been raised and flowered, and probably will be seen at the shows during the coming year. Several varieties of *Chrysanthemums* and other plants have been equally honoured, but those named will suffice to illustrate the Veitchian novelties of the year.

THE CULTURE OF THE APPLE.

[The following practical paper was read by Mr. G. Picker before the Members of the Lincolnshire Gardeners' Association.]

THE Apple is a national fruit, and when we have a small crop we seem to be short of almost everything for the kitchen in the way of hardy fruits, because the Apple can be used in so many different ways. I believe that if one-third of the Apple trees in England were grubbed up and burnt the country would not suffer any loss; indeed, there would be a great gain instead. In some cases there is good ground occupied by worthless varieties of Apples that are only thrown to the pigs. If good sorts were planted in their place it would be a gain in several ways. It would benefit the owner or occupier, also the nurseryman in a small way, and, in fact, the country at large.

It is impossible to grow Apples on wet ground without underground drainage. It will produce unripened wood or shoots, inferior fruit, and little of that. The first severe frost will kill the ends of the young growth, which is, I think, one cause of canker, and the stems and branches will be covered with moss, &c. Therefore, I consider wet land in its natural state useless for fruit-growing. If it can be well drained that will alter the case. Three feet 6 inches to 4 feet is a useful depth of drains for fruit trees. In some cases we have to be ruled by outfall; 14 to 18 feet is a reasonable distance, according to the tenacity of the soil.

ON THE IMPROVEMENT OF THE SOIL.

If the soil is unsuitable we ought to do our best to improve it. Lime is a grand improver in many ways, by opening and sweetening, killing insects, and making the ground dryer and warmer. Give strong, raw, cold land six tons per acre, put it on unslaked, and work it in at once. Try one piece as mentioned, leave the rest without giving any lime, and note the difference. It will be easy to see which had lime and which had not, especially in the working of the ground. Three tons of lime per acre is a fair dressing for land which is in good order as to working and fertility. I also consider burnt earth a capital improver of all soils. I have used, with the best results, one-fourth of burnt earth incorporated with the natural soil. Where there is plenty of burnt earth incorporated with the natural soil the trees make less wood, more fruit buds; they have heavier and better coloured fruit, the soil works more freely, and the whole growth of the trees is sturdier. Road parings and scrapings, ditch parings, carted into a heap, a good dressing of hot lime, all well mixed together, the heap turned over in six months, give a little more lime if required, and then let it rest for three months; then turn it over again, and in the meantime, if there is any liquid manure to spare, throw some over the whole heap. In twelve months' time from carting together it will be found a valuable help in planting trees of every description. The soil to be planted ought to have a depth of 18 inches to 2 feet if possible; less will do, but not so well in hot weather. It is better to raise the soil than to take out any stone or clay from under the top soil; lowering it makes it colder and damper; raising it makes it dryer and warmer in wet weather. The ground should be well worked and cleaned before there is any attempt at planting. If the land is poor or unfertile it should have a good manuring to begin with, sixty tons per acre will not be too much for poor land. The manure ought to be kept as near the surface as possible, as that will keep the roots there also.

PLANTING.

What do we want? Profit, ornament, or a few fine fruits to show? My idea is that if we want profit we should plant standards on the Crab stock; for ornament, and, for a few fruits to show, plant bushes on the Paradise stock. Pyramids will do well on the Crab stock, but they do not bear one-sixth part as well as the standard. One standard at thirty years old, if properly planted, will bear more fruit than ten bushes of the same age, even if they live as long as thirty years. To be successful we must make a good start. If for an orchard of standard Apple

trees, mark out the rows or lines 30 feet apart each way. Thirty feet is quite close enough to be useful or profitable. The distance to plant dwarfs or bushes on the Crab stock is from 10 to 12 feet, according to the soil and the variety, whether it be a weak or a strong grower. For dwarfs on the Paradise stock 8 to 10 feet would be a useful distance. If the subsoil were stony, I should not trouble to do anything to the bottom of the hole except to ram all down firmly. If there were clay or marl I should put in 6 inches of drainage at the bottom. First I should put in 3 inches of rough drainage, and then 3 inches of finer material on the top; then ram all down firmly, leaving the top of the drainage convex to draw the water to the sides of the hole.

For standards, make the holes 8 feet across or 8 feet square. We will say that there are 18 inches of good soil, all of which we have taken out. Take out 6 inches of the lower or bad soil, placing in the drainage. The drainage being all in, mix with the natural soil some fresh compost. The heap mixed with lime and turned over will be useful now. Fill the hole to within 6 inches of the top, tread it down as it is put in if in working order, otherwise leave it for a few days. Drive down a strong stake in the centre of the hole, put the tree to be planted against the stake, give one tie round the tree and stake to keep all steady, spread out the roots evenly, and cut off all decayed and bruised portions. Cover all the bottom layer of roots, then lay out the top layer of roots, cover them, and tread down firmly. Leave the collar of the tree bare 1 inch and the soil concave, for top-dressing and holding water; stake securely. Drive down three stakes at equal distances from the stem; fasten three wires round the stem, first placing some old carpet to prevent injury; then take one wire to each stake; fasten securely; drive down each stake 1 or 2 inches to make all tight; give 6 inches of long manure for a mulch to keep out the cold, then all will be safe. The holes for the dwarfs ought to be 6 feet across and served the same as for standards. One stake will be enough for dwarfs, put at an angle of 45°. Drive it into the ground 3 feet from the stem, then bring it close to the stem and tie it.

TIME TO PLANT—PURCHASING THE TREES.

The end of October and the beginning of November is the best time in the year for planting fruit trees. Those properly taken up and planted again in October and November grow the following summer very little the worse for their removal. We may plant from October until February, weather permitting. Trees planted late will cause much more care and trouble in watering and will not make nearly so much growth.

It is better for purchasers to go to the nursery and choose their own trees. It is cheaper in the end to pay more for having the pick of the trees than to have what other people leave.

THE WRONG WAY TO PLANT FRUIT TREES.

Make a start on some ground that has been worked 6 or 9 inches deep. Dig out a hole 2 feet square and 3 feet deep, get some fresh soil and mix with the natural soil; never mind the subsoil. Fill in the hole with the mixed soil up to 1 foot of the top, plant the tree, cover the neck 6 inches to save staking, the trees waving to and fro with the wind; the planter waiting two or three years; the trees doing very little good. The only person blamed for things not going on as well as was expected is the nurseryman for sending out bad trees, just as in the same way the honest seedsman is blamed for sending out bad seeds, when in nine cases out of ten the fault lies with the sower.

ROOT-PRUNING.

There are several ways of performing this operation. The way that I have found the best is to take out a trench 4 to 6 feet from the stem, according to the size of the tree, digging down as deep as the roots go. I generally cut all the roots off where I start, except three or four small ones that run near the surface; these I leave for the support of the tree after the shortening of the stronger and deeper roots. It is easy to lift the trees nearer the surface if required. When so treated I work out the soil from underneath the tree; if the drainage is bad I add more, and beat all down firmly, then add one-fourth of good fresh compost, fill in the hole with some of the compost mixed with the soil taken out. Lay out the bottom tier of roots, cover them over with good soil, then lay out the next tier, cover over 5 or 6 inches, make firm, mulch with 4 inches of long manure from the stable. I have raised up trees 9 to 12 inches in the operation, changed trees affected with the "yellows," and which produced only very poor fruit, into trees bearing beautiful and green foliage, and fine fruit, after the treatment described.

I have seen root-pruning done with a vengeance—chop off the feeding roots, leaving the robber or robbers safe. Then I have seen trees that have been root-pruned that required propping

up after the ordeal of root-pruning. That kind of cure is worse than the disease.

MOVING APPLE TREES.

In the first place we must look what kind of tree we wish to remove, then we must see where we wish to place the tree after removal. We must make the hole for the new tree before it is taken up, or else have both operations going on at the same time. If a tree of from 10 to 12 feet high, then we must begin 7 or 9 feet from the stem, and take out a trench. Take out the soil with a steel fork to avoid injuring the roots. If there are any roots that go straight down, they should be cut off. Leave as large a ball of soil as there is strength to get the tree out of the hole. When the tree is undermined and ready for removal, of course the new home should be ready—that is, prepared the same as for standard trees, only larger if required. Planks should be put underneath the ball, lift it out of the hole, if not too large. If too large make an incline down to the roots. I also make an incline down to the side of the new hole, run a low truck down, ease the tree a little on one side, get the truck underneath, get loaded, draw out, take to the new hole, run down the incline into the middle of the hole, unload, draw out the truck; lay out the roots carefully in tiers the same as they grew before removal. When the hole is half filled, about 30 or 40 gallons of water is a capital addition in the way of fastening the tree. Let the water settle, then fill in the rest of the soil; mulch, and stake as advised for the standards.

FEEDING THE TREES.

In ninety cases out of a hundred, big things are not so easily overlooked as small ones. Apple culture is no exception. It is generally known that a great many Apple trees only bear every other year. I think the cause of that, in a great many cases, is want of food for the support of an annual crop. How can we expect fruit trees to produce a crop every year without being in a wonderfully productive soil without feeding? If trees are properly planted at first, and the roots still in good order, they will readily respond to any little help they may receive. When trees are annually bearing heavy crops without assistance, the soil must soon become exhausted through overcropping. Give abundance of liquid manure, the colour of Burton's shilling-per-gallon beer. Bearing trees want feeding all through the winter with plenty of liquid manure, provided the drainage is good. Trees well fed start away so much stronger in the spring than trees that are not so treated. The frost does not seem to have the same effect on well-fed trees, as those on stunted growth. I do not mean trees making a growth of 3 and 4 feet in one season or more, 10 to 15 inches is quite enough for bearing trees to make of new growth in one season. When the trees have got into an exhausted state through overcropping in arable land, take off 4 inches of the top soil as far as the roots extend, then add 6 inches of good decayed manure in its place. If on grass land, add the manure as a top-dressing. The autumn is the best time for that kind of renovation. In the following summer pour plenty of house sewage or liquid manure over the manure. I think that would be a remedy for debility if the trees are not too far gone or worn out. My idea is a good constitution, work well, and feed well.

PRUNING THE BRANCHES.

I can only say a few words on this subject. We cannot be too careful with the knife and saw. I do not mean that we ought not to use them—we cannot get on without them, but we want to have an idea of what we are going to prune. In the first place, we ought never to allow one branch to cross another if it is possible to avoid it. It is possible to prevent branches crossing if we take it in time. Begin with young trees, keep the branches thin enough, so as to allow the lateral branches to be no nearer than 12 inches, six main branches are quite enough for standard heads, and the main branches. Never allow any long rambling shoots to run away from the body of the trees, cut them clean out. We ought to try and keep every kind of tree as evenly balanced as possible. This plan is not difficult if we go the right way about it. Rub off all the shoots that are not wanted, stop those that are out-growing their limits or getting out of bounds. October is the best time to thin out branches where crowded. We can see much better how much to cut off when the leaves are on. November is the best month for ordinary pruning. Always cut to a bud pointing the same way you wish the shoot to grow. Nine inches is quite close enough for laterals to grow with small leaves; 12 inches is close enough for varieties with large leaves. Where trees are pruned early the buds break much stronger in the spring than trees do which are pruned late. It is a good plan to go over the trees the end of May or the beginning of June, and rub off all useless buds and

shoots that are not wanted for the formation of the trees, also to go over the trees every fortnight throughout June, July, and August to stop the branches or shoots so that they do not rob the weak ones or weak branches. Sawing off branches is a kind of pruning in which I have taken great interest, both in fruit and forest trees. I believe the worst kind of pruning to be where a branch has been sawn off a few inches from the stem, and left in that way. After a few years the snag generally dies and carries decay into the tree, whereas if the branches are cut close to the main stem, and evenly finished off with a carpenter's chisel, then dressed with a mixture of soot and cow dung, the wound will in time heal if the tree is healthy. The best way, I think, when a branch has to be sawn off, is to saw it in two pieces; cut the first portion of 18 inches or 2 feet from the stem to save accident to the tree. Cut one-fourth through on the under side first, then commence on the upper side, cut through; then cut the remaining piece through in the same way, on the under side first as before; finish off with a carpenter's chisel, make the cut quite smooth, and paint with soot and cow dung. Sometimes very large branches want cutting off at from three to six different places, or perhaps more, to save breakages.

GATHERING THE CROP.

There is great care required in gathering and storing fruit. Fruit is scarcely fit to look at when all the stalks are broken off in gathering, and this is not all. A great many fine fruits are first decayed at the junction with the fruitstalk through the rupture caused by the careless gatherer. I believe often one-third of the Apples and Pears are spoiled in the gathering and storing. What is the use of going to the expense of producing good fruit if there is not a suitable place to store it in when gathered? It is as though a man bought a horse and then had nowhere to keep it. To keep fruit well we want a place similar to a good cellar, with a regular cool temperature of from 40° to 45° Fahr. as near as we can get it. The time to gather the fruit is when it will part freely from the tree with lifting up, also when good fruit falls off without the wind blowing it down.

CANKER AND INSECTS.

Frost may cause canker when the wood does not get properly ripened. I know that when the roots get into a bad subsoil that will cause it. Lifting the roots out of bad soil and putting drainage and fresh soil, plenty of burnt earth, and old turf if it can be had will cure it if it is not too far gone—that is, the branches not eaten half through with it. The woolly aphis or American blight is a troublesome pest to deal with. I have found 1 oz. of petroleum mixed in one gallon of water, kept well agitated and syringed on the infested branches, checks its operations. The trees will want syringing about four times during the summer and autumn. When one tree is finished commence to syringe off the oil at once, then no harm will occur to the trees. Methylated spirits of wine is a great help in keeping it down. Get a small brush, dip it into the spirits of wine and just touch the insects. This will make short work with them. Bare a few of the large roots, and let them remain so most of the winter. Give a good dressing of hot lime, that will help to get rid of them as well for green fly. Give a good dusting of tobacco powder at night when the trees are damp, or syringe them. Syringe the powder off again next morning; in about four days dust again; that will also generally check green and black fly.

The following is a list of a few good varieties of Apples:—

Dessert Varieties.—Kerry Pippin, Red Astrachan, Irish Peach Cox's Orange Pippin, Ribston Pippin, Margil, Blenheim Pippin, Golden Winter Pearmain, Fearn's Pippin, Court Pendu Plat, Scarlet Nonpareil, Dutch Mignonne, Lord Burghley, Sturmer Pippin.

Culinary Varieties.—Early Julian, Domino, Lord Suffield, Stirling Castle, Golden Noble, Warner's King, Small's Admirable, Cellini, Alexander, Blenheim Pippin (one of the best), Dumelow's Seedling, New Hawthornden, Gloria Mundi, Alfriston, Rymer Yorkshire Greening, Bess Pool, Striped Beefing.

MUSHROOM CULTURE—CHRYSANTHEMUMS.

NOTWITHSTANDING all that Mr. Wright has done to show how easily Mushrooms can be cultivated, and that others have also shown repeatedly through the gardening press, as well as practically, how this can be accomplished, it is astonishing how many still believe that a supply of Mushrooms without the aid of an orthodox Mushroom house is a fiction. When in Leamington not long since I called to see Mr. Crump at the Ranelagh Gardens, and I found some excellent crops of Grapes there too, but I allude to Mr. Crump here because of his success as a cultivator of Mushrooms under very easy circumstances. In his Cucumber and Melon houses, and, in fact, any other house where he can make up a bed, he

utilises such space for his Mushroom beds, simply covering them with a little hay, and he gets a large quantity through the winter from these beds, and finds, what would alarm so many, that the light admitted through the glass roofs is a decided advantage to the Mushroom in size and quality. A few days since I met with another example of highly successful Mushroom culture in a cool greenhouse underneath a plant stage. The space was boarded off into divisions about 3 feet square, and about 18 inches of ordinary stable manure, the straw being taken out, was placed, after being prepared in a shed. As soon as ready the manure was spawned, and 2 inches of ordinary soil placed upon it, and a wood shutter placed in front. Mr. J. Crook, who is gardener to W. Millward, Esq., Edgbaston, Birmingham, has adopted this plan yearly for a supply throughout the season, and obtains a wonderful lot of fine Mushrooms, and is rarely without them by spawning and working the beds in succession, and begins cutting from six weeks to two months after spawning. He uses Barter's Mushroom spawn, a very excellent stock, which appears to rival in quality the well-known milltrack spawn. Really the cultivation of the Mushroom is so very easy that it is to be regretted that so many more do not try it, as it can be done in cellars, outhouses, and so many odd places not really wanted for other purposes.

Mr. Crook is unquestionably one of the best amateur Chrysanthemum cultivators in the Midlands, and has made his mark at the Birmingham Chrysanthemum exhibitions. I was much pleased with his pyramidal Pompon plants, which were well grown and flowered. For such plants he cuts down his half-standards after blooming, and takes away all the suckers, leaving only the young shoots on the main stem. The plants will shortly be turned out of pots, shaken out, repotted, and tying and stopping will be attended to. I shall be very glad to see at our Chrysanthemum exhibitions a much larger number of naturally grown plants, but to get exhibitors out of the old groove of growth special classes must be made for them. I have seen many beautifully grown plants this year which were stopped in May and made comparatively dwarf well-grown plants with well-developed foliage to the pots and exceedingly well flowered.—GUILLAUME.

THE DIFFICULTIES OF LIFE

THE obstacles to be surmounted while we journey through life are many, and gardeners have their share of them. What is the gardeners' position? Have they been exempt from the almost universal distress? No, certainly not. Have not many of our finest establishments been reduced, while others are now sending part of their produce to market? a course that has considerably affected the price of garden produce to the disadvantage of many a struggling hard-working man who is depending entirely on this industry.

Many of the youths who enter gardens in country places find in their limited education their first difficulty. They find botanical names and other technical terms strange, and without assistance are a long time before they become familiar with their pronunciation and meaning. The next may probably be the difficulty of books, for out of a very small wage there is generally not much to spend in standard works the first year or two. Thanks to our many horticultural papers, there is no want of useful reading within the reach of all. This is one advantage our young men of the present have that was not enjoyed fifty years ago. When several young men are together there is always to be found amongst them a few books, and in some bothies the employer kindly provides a stock of books and also of the periodicals, which is a very commendable practice. A young man who finds himself favourably situated, and is inclined to study, may soon improve his defective education, and at the same time pick up a knowledge of many things necessary in connection with gardening. A great number of our young men are not thus favourably placed. It is a great disadvantage to be housed in a miserable hovel and without a companion, as many are, and still worse to be so placed with a bad companion. If one is alone and has access to books he can study at peace, though at a disadvantage, as there is no one to assist or exchange ideas; but when a lad is placed with one who has no interest in his work he is apt to be led away or otherwise deterred from study by noisy amusements and frivolity.

Many young men think that when they get a "head place" their difficulties will come to an end; but they soon find their mistake. Their masters are not prepared to give them all the hands they may think necessary to keep everything in order, while the lady of the establishment may be very particular about this or that being done just so, and at once, regardless of what her gardener may have on hands or its importance. Again, his master may not be disposed to build new houses and spend large sums of money for plants to fill them to suit the demands for cut flowers and plants for room decoration, &c., though the one may be altogether out of proportion to the other.

Some ladies are very particular about having their conservatory, which may be in connection with the house, always full of flowering plants; but they do not consider whether the accommodation for keeping up a supply is sufficient, and are often so inconsiderate as to cut flowers from them, thus giving endless extra labour for the gardener in continually bringing fresh plants to take the place of those cut from. This is often a gardener's grievance, but if the matter was better considered by ladies it would not be of such frequent occurrence. If they are fond of having their conservatory gay, they should look about other houses first for blooms, and they will generally find them, and right willingly will most gardeners see them cut and assist in getting any that may be out of reach, so that it saves cutting from plants specially grown for conservatory or house decoration. It is a delicate point for a servant to protest against even in

the most polite manner, as it may lead to the conclusion that the gardener is averse to cutting anything. Quite the opposite is generally the case. I, for one, like to see ladies cut and arrange their own flowers if they would do so judiciously, so as not to disfigure or injure the plants cut from, nor from groups specially arranged for effect. A good understanding between a gardener and those who like to gather their own flowers would remove one of the gardener's difficulties.

Gardeners sometimes have a difficulty in supplying vegetables in sufficient quantity to satisfy the demands of a large family or an extravagant cook. His garden may be too small crop it how he may, or the soil may not be very favourable for certain things standing the winter, and often those are just what is most wanted. Some cooks have a craze for Spinach all through the winter months, and nearly all want an endless supply of Parsley, two vegetables not very plentiful at certain seasons, but as sure as the supply is short the demand is certain to increase. Another difficulty is in knowing what to grow in quantity. A cook may want an extra supply of some vegetable, but before you get it grown she may be gone and another in her place, who may not use it, but wants a lot of something else for which the puzzled gardener is not specially prepared to supply. When a man has plenty of ground and hands to work it, no difficulty need be experienced; simply grow plenty of everything. But when a garden and other means are limited, and he wishes to grow only what will be used, it is no easy matter to do so without running the risk of coming sadly short of something else when brought face to face with a new cook. Again, some cooks will be satisfied with a very few herbs for flavouring her soups, while another will have a bit of everything in the garden in that line, and regrets that you have not got so and so. "Soup is nothing without it, you know," they will tell you.

There is also the difficulty of growing too much, which some have to contend with—by no means an agreeable side of the question—which has grown more so and of more frequent occurrence of late years. Give a good-sized garden, which will produce more than a small family will or care to consume. We are probably told that times are bad, and that we must make the most of fruit and vegetables that is to spare by sending them to market. You have very likely never been called upon to do this before. The first difficulty will be to find anyone to take your small quantities sent at indefinite periods. Such perishable fruits as Peaches, for instance, may all be used up one week, but not the next. You disappoint the man you sent them to a few times in this way, he looks elsewhere for a more certain supply, and probably when you send a larger lot than usual he will write to say he is "overstocked" and can only give so and so—half the value of fruit very likely. Your master sees the list of prices in Covent Garden, or may have occasion to be in a first-class fruiterer's shop, and have the curiosity to inquire the price. He compares that with the prices he has been getting and cannot understand it. He comes home convinced that he is being cheated in some way. If he is a straightforward gentleman he will speak about it at once, have it talked over with his gardener, and come to a proper understanding. But some gentlemen will not do this, but keep brooding over it, generally putting all the blame on the gardener, and sometimes even going as far as to question whether he is altogether honest. This marketing business is generally unsatisfactory to both employer and gardener. The former thinks he should have more for his produce. The latter thinks so too, but with a limited quantity, and that at the best irregular, he fails to see how he can do better. He also feels that fruit, &c., thrown thus into the market is a serious injury to market growers.

Amongst many difficulties, the weather is often unpropitious, and presents obstacles to overcome. When we begin to think "Gloomy winter's now awa," &c., she suddenly returns, carrying in her wake devastation amongst the tender fruit blossom. In the summer he has the drought to contend with—water, mulch, shade; and next thing will be a downpour of rain, battering his flower beds, splitting his choice Plums and Gooseberries, &c., and making weeds spring up in thousands in every direction.

"When biting Boreas fell and dour
Sharp shivers thro' the leafless bower,"

he has to think of many things. Shutters for various plants, flowers, and vegetables, not very plentiful sometimes, and fuel sometimes not very cheerfully given. There is the difficulty of enemies innumerable, small and great, and at all seasons. Bullfinches eat his fruit buds in winter; sparrows devastate his seed beds, his rows of Peas, &c., in spring and summer; and the thrushes and blackbirds devour his fruits. Amongst the creeping things there are slugs and snails, there are weevils and wireworms, and centipedes and caterpillars, grubs, green fly, scale, and bugs. In the face of such a host of enemies his policy must not be one of "peace at any price," but one of war.

But with all his difficulties has not the gardener many pleasures in the pursuit of his profession? Has he not one of the healthiest occupations, pursued in pleasant places, surrounded by Nature's choicest treasures from various parts of the globe? Does not the gardener have an equal pleasure and pride in seeing his master's table adorned with the choicest of fruits and flowers? Is it not a pleasure to have the confidence and respect of a good master, as thousands of gardeners have, enjoying a comfortable home away from the influence, the turmoil, and ups and downs of trade and commerce? And it is encouraging to know that many a worthy man is well provided for by a liberal master when he is bowed down with toil and age, and who enjoys a well-earned repose in the autumn years of his life, with but few difficulties to mar his meditations. Let us hope there are but few masters who would part with a good and faithful servant because of his years. But, at the same time, let each and all do something for themselves in their early manhood, and by doing so

help others, and then may expect some return in his declining years as a right, not of charity. Let me close these rambling thoughts by enumerating one more pleasure a gardener has—at least, I have a special pleasure, and am sure many more have—namely, the pleasure of reading the Journal every Thursday evening. To its Editor and its many readers I wish a happy New Year.—A WORKING GARDENER.

A USEFUL MANURE.

I WISH to bring before the notice of your readers a valuable manure too often neglected—viz., night soil. When properly prepared I know no manure to excel it in effectiveness, not even excepting the famous guano. It is more regular in its action than the former, and there is no risk in the use of it, like guano when used as a liquid manure. For Cockscombs, Gloxinias, Celosias, and Chinese Primulas it is excellent, and the latter seem to be especially at home in whatever soil the manure is mixed with. They can be grown easily to 18 to 20 inches span of foliage, producing large blooms snperb in colour. I find it best to use very little leaf mould with this manure for Primulas, as they have a tendency to produce too much foliage. We grow all our Zonal Pelargoniums in 4-inch pots only, and with this manure they do extra well. On such kinds as Rev. A. Atkinson, Masterpiece, &c., I have had at one time six fully expanded trusses of bloom measuring from 15 to 19 inches in circumference, and that continuously through the season. One plant of Monroe's Little Heath Melon grown in a box containing one pailful of turfy loam and one of this manure produced four fruits 14 lbs. in weight; and one plant of Daniel's Duke of Edinburgh Cucumbar produced seven fruits from 24½ inches in length and 8 in circumference to 27½ long and 9½ inches in circumference, and straight as a ruler, with splendid bloom, and all the former receiving pure water only.

In preparing the material to mix with the night soil proceed as follows:—Procure some clay soil as heavy as possible, and let it dry, then get as many branches, old pea stakes, or any refuse of that kind, and make a good ring of them to begin with; then put on a layer of earth and sticks alternately, keeping the whole well together, leaving only a small aperture at the top to allow the smoke to escape and prevent it from blazing. If some bog earth be added it will be a benefit to the mixture, and when burnt out it may be watered and mixed. It is then ready for use in the closet, to which it is conveyed by a tin pipe with two stops in it similar to that in a powder flask, for regulating the supply. The calcined earth and charcoal, prevents the various gases from being dissipated in the atmosphere; the rough portion falling to the sides secure the phosphoric acid, potash, &c., contained in the urine. Or if having a quantity of night soil on hand, mix it with half the bulk of the earth, and leave it in some dry airy place for eight weeks or so. It will be found in a condition for mixing in any compost, being minutely sub-divided by the action of the earth and perfectly inodorous. I do not advance this as anything new, but as a simple means of securing all the good contained in so valuable a manure.—J. SWAN, *Kilmalcolm, Renfrewshire*.

WRITING in reference to the note on page 539, Messrs. JAMES CARTER & Co. observe that the prizes offered by them are open to all amateurs and gentlemen's gardeners, and that the error pointed out on the page quoted was corrected before any great number of copies of the "VADE MECUM" had been printed.

THE ROYAL BOTANIC SOCIETY'S EXHIBITIONS FOR 1886 are fixed for the following dates:—Spring Exhibitions March 24th and April 14th. Summer Exhibitions May 19th and June 9th. Evening Fête June 30th. There will be an exhibition of American plants daily during June. Promenades take place every Wednesday from May 5th to July 28th, except May 19th and June 9th and 30th. Lectures at 4 P.M. on Fridays May to June.

THE ANCIENT SOCIETY OF YORK FLORISTS held their annual dinner on the 23rd inst. at the White Swan Hotel, York, the City Sheriff, Mr. Samuel Wright, presiding. A number of toasts were proposed and honoured. Three silver cups, which were given as special prizes at the recent Chrysanthemum Show, held under the auspices of the Society, were also presented to the winners. The first—the City Sheriff's prize—was given to Mr. R. F. Jamieson, Hull, for the best thirty-six Chrysanthemum blooms. The next was the officers of the Society's prize, awarded to Mr. John Fielden, High Sheriff of Yorkshire (gardener, Mr. H. J. Clayton), for the best six bunches of Grapes, three varieties. The third prize—

given by the Mayor of York—was taken by Mr. Robert Baker, of The Retreat (gardener, Mr. J. Doe), for the best group of Chrysanthemums.

A PROOF extract from the annual report of the METROPOLITAN PUBLIC GARDENS ASSOCIATION has been forwarded to us, and from it we learn that much good work has been performed during the year. Taking the three past seasons the following are given as the expenditure in improvements of various kinds:—1882-3, £849 3s. 2d.; 1883-4, £1159 11s. 3d.; 1884-5, £6587 1s. The total being £8595 15s. 5d. It is said that to carry out the work in hand about £4000 will be required. A considerable sum (£3642 2s. 6d.) was raised to be expended as wages to the "unemployed," and £864 remains to the credit of the Society, but additions are much needed to the General Fund, which is kept separate.

MESSRS. H. CANNELL & SONS, Swanley, send us a large plate representing varieties of DOUBLE TUBEROUS BEGONIAS, of which so many greatly improved forms have been obtained in recent years. Some of them are most symmetrical in outline, with the petals as evenly arranged as in a Camellia or Ranunculus. A variety named *Pæoniflora* with globular drooping flowers is particularly useful for suspending in boxes or baskets.

THE seed catalogue of a Continental firm gives a description of a SEMI-DOUBLE PELOX DRUMMONDI which is said to be "of dwarf compact growth with double and semi-double flowers. This new variety is not yet quite constant, the scarlet colour excepted." Judging from the woodcut the flowers are not unlike those of the double *Bouvardia* in form.

ON Thursday evening, the 24th inst., a large and influential gathering of gentlemen took place in Carmichael's Temperance Hotel, Bridge of Allan, for the purpose of presenting A TESTIMONIAL TO DR. PATERSON in appreciation of his long and valued services as a doctor in Bridge of Allan and neighbourhood. Mr. Laurence Pullar, chief magistrate, occupied the chair, and the Rev. Dr. Ross performed the duties of croupier. There were also present—Dr. Haldane, Dr. Rogers, Colonel Blair, Messrs. T. Cumming, Wm. King, John Henderson, H. Robertson, Wm. Reid, R. Greenhorn, Wm. Cousine, Wm. Haldane, J. H. Henderson, and many others. In the course of several speeches, Dr. Paterson's services as "father and founder of Bridge of Allan" were referred to in flattering terms, his experience as a medical man and his knowledge as an antiquary and amateur horticulturist also receiving appropriate recognition. The presentation consisted of a cheque for £340, enclosed in a silver casket, bearing the following inscription:—"Presented to Dr. Alexander Paterson, along with a cheque, given by 260 subscribers over the whole country, in testimony of their regard for him as a successful physician, a kind friend to the poor, and a public benefactor to the inhabitants of Bridge of Allan."

GARDENING APPOINTMENT.—Mr. W. Swan, who has been gardener at Oakley, Followfield, Manchester, for many years, and has lately been Honorary Secretary to the Manchester Horticultural Improvement Society, has now left the district, having been appointed head gardener to E. G. Wrigley, Esq., Howick House, Preston, Lancashire. Mr. Upjohn of Worsley Hall Gardens, Manchester, succeeds Mr. Swan in the secretaryship of the Society named.

THE second volume of the ILLUSTRATED DICTIONARY OF GARDENING, published by G. Upcott Gill, 170, Strand, continues the subjects in the same manner as in the preceding volume, from *Faba* to *Ozothamnus*, and contains a great number of illustrations from various sources, the majority being good representations of the respective plants. A commendable accuracy is observable throughout, and the cultural information is reliable. A coloured plate of *Snowdrops* forms the frontispiece to a neatly printed and substantially bound volume.

A CORRESPONDENT gives the following as the number of BEDDING PLANTS USED IN HYDE PARK during the past season:—One hundred thousand *Pelargoniums* in over 100 varieties. Amongst the favourites were: Henry Jacoby, Rev. Atkinson, Mrs. Turner, and *Eurydice*; 60,000 *Lobelias*, 70,000 *Alternantheras*, 5000 *Heliotropes*, 5000 *Ageratums*, 30,000 *Calceolarias*, bedding varieties, 60,000 *Echeverias*, 2000 *Begonias*, single, 1000 *Fuchsias*, 20,000 *Coleus*, 20,000 *Carnations*; *Pyrethrum* is not much used, but 50,000 *Spergula aurea*, 40,000 *Golden Creeping Jenny*, and 40,000 *Cinerarias*, besides *Celosias*, *Centaureas*, and other annuals and varieties of bedding plants.

WE learn that "ILLUSTRATIONS" is the title of a threepenny monthly magazine which, under the editorship of Mr. Francis George

Heath, will commence in January. It is designed "to occupy a position not yet filled," and will be "a pictorial review of knowledge of all kinds, comprehending amusements, art, domestic economy, inventions, literature, and science." The publishers will be Messrs. Wells Gardner, Darton and Co.

— AN American writer wishes that "the name CHRYSANTHEMUM could be shortened, as it causes some trouble to those who are not familiar with botanical names. We hear them called Cassanthiums, Chrysanthiums, as well as Chrysantumbums, Chrysants, and Chryschianthems." To these might be added a daring abbreviation in common use amongst English growers—namely, "the Mums."

— WE have received a copy of SUTTON'S POCKET GARDEN CALENDAR FOR 1886, a neat little production, giving with the ordinary calendrical matter, condensed instructions in garden operations for each month.

— THE *Journal des Roses* for December gives a coloured plate of the Hybrid Perpetual Rose, GLOIRE DE BOUCHET, which is said to have been raised at Bouchet, the residence of M. Maxime de la Rocheterie, the President of the Orleans Horticultural Society. It appears that the gardener, M. Pignard, sowed a number of seeds selected from the best varieties, and amongst the resulting progeny the variety named was almost the only one which attracted much attention. It was subsequently tried by M. Scipion Cochet at Suisnes, where it proved quite satisfactory. In colour it is described as approaching Margottin's Maréchal Forey, and in general characters as resembling Gonod's Madame de Moreau, but with larger flowers and of a more lively colour, a bright reddish scarlet.

TRAINED SPECIMEN CHRYSANTHEMUMS.

ON page 546 Mr. Iggulden says he should not be grieved if these were altogether excluded from shows, and that he believes many share in his opinion. I am inclined to think that he is only one in a thousand. I say, as before, that a flower show is nothing without good specimens, whether they be Chrysanthemums or any other plants. Your correspondent wishes to know if they are profitable. We do not grow them for profit; they are grown for the pleasure of their owner. Mr. Iggulden also wishes to know how they look at home; they look equally as well as at the show, and I think a little better, because they are more effective by being mixed—incurved and Japanese, and Pompons together—grouped as Mr. Iggulden prefers; but they are all trained specimens, and they are greatly admired by my employers and their many friends. Our visitors give me great praise for the training. Mr. Iggulden says they require much more house room than they deserve. In my opinion they well deserve the house room they require, and if this cannot be had no one ought to attempt to grow and train them as specimens; nor should persons who have not the time nor the skill. I admit if they lose their foliage and show the stakes they look very unsightly, but well-grown plants are not in that condition.

Mr. Iggulden may think because I grow so many of these that I have nothing to cut from. That is not so. I have been cutting Chrysanthemum blooms in abundance from the middle of August up to the present time for home decoration, and many boxfuls have been sent away to other places. It may "grieve" Mr. Iggulden more when I say that my employers want me to grow a larger number of these specimens than I have ever done. It may please your correspondent, perhaps, if I tell him that I had thought of giving up showing, and it may be so, but the plants will be grown just the same and more of them. I have nothing to say against grouping as your correspondent prefers. I like the style very much, and should like to see more of it at the shows; but for all that I am in favour of trained specimens when well finished. I should like to know what the Committees of the different Chrysanthemum Societies have to say about trained specimens being admitted at their shows—do they prefer them or not?—W. MONK.

THE cultivation of the above should be encouraged, and liberal prizes offered at our annual exhibition for competition, and should include every variety. Among the pleasing but beautiful varieties, some of them extremely novel in character, exhibited by Messrs. H. Cannell & Sons of Swanley, many could be found that would prove highly interesting on the exhibition table, would not require so much staking, and would be a source of attraction at home as pot plants. My friend Mr. Monk and myself can recall a period of thirty years ago, when some grand specimens were shown with healthy foliage and abundance of flowers. They were selected on account of their adaptation for pot culture. I have listened to the throng of horticulturists who would admire and discuss the merit of those marvels of productions as exhibited by Messrs. Scruby, Wetherall, Ward, Holmes, Wiggins, and George—the majority of which enthusiastic cultivators are gathered to their fathers. We have seen some fine blooms this year, requiring superb skill to produce them, but we should not forget all tastes are not alike.—J. F. McELROY, *Camden Hill, Kensington.*

COOK'S EARLY CABBAGE.—I see in the *Journal* that Mr. Inglis and Mr. Oliver have each sent you a packet of Cabbage seed for trial. I take

the liberty of sending one also of what I consider the true stock of Cook's Early Cabbage, having grown and saved the seed of it for twenty years, the stock being obtained from Mr. Cook. This is a good spring Cabbage, but to have it in perfection sow in July and plant in September, and Cabbages will be produced second to none for quality or earliness.—S.

[The seed shall be sown with the other in due time.]

THE MONARCH PLUM (RIVERS).

THIS Plum was raised from a stone of Cooper's Large Red, generally known in this country as "La Delicieuse" or "Lady Lucy" of some of the Kentish fruit-growers, and said by Downing to be raised by Mr. Joseph Cooper of New Jersey from a stone of the Orleans. The fruit of the Monarch is very large, and in shape roundish oval, a dark purplish blue in colour; it is freestone, with solid flesh of excellent quality. The young shoots are downy, but the down disappears on the older wood. The growth of the tree is very robust, forming a vigorous natural pyramid, and producing fruit spurs in abundance at an early stage. The fruit ripens about the 25th of September in the south, and is quite free from any tendency to crack. It is therefore likely to prove a valuable fruit for the grower, ripening after the glut of other Plums. Cultivated, on walls or as a cordon it will produce very fine specimens, and as a standard or pyramid it makes a very prolific tree. The Grand Duke, another large late Plum, also originated from the La Delicieuse.

STRAWBERRY PLANTS IN WINTER.

UNDER the above head your correspondent, "A Kitchen Gardener," refers to the winter treatment of Strawberries in pots for forcing, which is, without doubt, a subject well worthy of discussion at the present time. I think the majority who force these plants in any quantity commence operations long before March, and have by that date many hundreds of plants in different stages of development. Such must be the case in all establishments where the fruit is required early in the season, as it is possible to produce them, and a continuous supply maintained afterwards for use daily or to be packed two or three times a week until they can be gathered outside. This is the position of many, and perhaps at no season are Strawberries more welcome than during the early months of the year, when the number of dishes for dessert are somewhat limited.

I was under the impression that some of the ideas put forward by your correspondent on the treatment of the plants during the winter were obsolete. For instance, the system of storing the plants in a heap by packing row after row one above the other with straw, litter, or ashes amongst them cannot be too strongly condemned. The other plan advocated by "A Kitchen Gardener" of storing them under a wall on their sides and allowing them to become dry should not be practised. Both these systems are unnatural and prove exhausting to the plants. The Strawberry plant during the whole of the winter months is naturally moist at its roots, and why should the opposite extreme be practised with this plant when grown in a pot? Your correspondent knows that this drying system is radically wrong, for he says, "These are not kept so dry at the roots as those at the bottom of the wall," this having reference to those plants stored in a cold frame. The above clearly shows that "A Kitchen Gardener" does not believe that the plants are benefited by being kept dry, or he would practise the same treatment with those protected in a frame. It appears to me that he is prepared to sacrifice that which is of vital importance to the well-being of the plants for the mere purpose of protecting a few pots from being destroyed by frost. Not only does your correspondent practise this treatment, but he advises others to subject their plants to an unnatural system for the same purpose. If this is the only reason that can be adduced for keeping the plants dry the least that can be said for it is that it is a very poor one.

In no stage should these plants be dry at their roots, and all who may wish to preserve their plants in the best possible condition, whether they be few or many, should not adopt a system likely to prove injurious to the plants. The Strawberry is perfectly hardy, even when grown in pots, and has not been injured in the least when the temperature has fallen below zero during very severe winters; in fact, we have always found these plants start more quickly into growth after being exposed during a sharp winter. During the severe weather alluded to we have not lost more than perhaps a score or two of pots out of 1500 or more. This has generally been due to the pots being partially exposed instead of being covered with the material used for protecting them.

My advice to all is to keep their plants outside, for they will pass the winter just as safely as if in cold frames, and will start with greater freedom into growth. In order to protect the pots they should be plunged after growth has ceased in ashes or amongst leaves. In whichever they may be plunged the rim of the pots should be protected as much as possible. I am never particular about the pots being filled with the ashes or leaves used for plunging as long as the crowns are not buried. When the plants are plunged as thickly together as possible very few pots will be broken. If strong the plants will possess large leaves, which will extend well beyond the pots in which they are growing, and these assist in protecting the rim of the pots. If very severe weather sets in and is likely to last, mats are placed over the plants, or a little clean dry straw. This protection is given to protect the pots, the plants would be better

without it. During the whole of the time the plants are outside they are not allowed to suffer by want of water; should they show signs of being dry they are watered. Our plants remain outside from the time they are

not forced so early as those that have remained outside. This is only what need be expected if he closes the frame and protects them from frost, for the plants protected would not be so completely rested as those

FIG. 86.—THE MONARCH PLUM (RIVERS').

layered into their fruiting pots until they are removed indoors in batches to be forced.

Your correspondent states that the plants protected in cold frames do

exposed. If I placed my plants in frames they would be freely exposed to all ordinary frosts, and only protected by closing the frames during very severe weather, and then not for the benefit of the plants, but for the

purpose of preserving the pots. Cold frames and cold houses, such as vineries and Peach houses, should be avoided for these plants until growth has been brought to a standstill and the plants have rested, for after this no harm will be done even if they are brought gradually forward in such structures. But if placed in them before they have been exposed to a few sharp frosts they do not rest, but continue growing slowly, and when wanted to come forward quickly in heat they fail to do so.

However early runners may be taken in the season and ripened in autumn they fail to start quickly into growth when introduced into the forcing house unless they have been exposed to a sharp frost or two. A few early frosts in autumn are of the greatest advantage, and should be welcomed by all who have to produce ripe Strawberries as early in the season as possible. If a batch of plants are placed in the early Peach house or vinery when started before any frosts have occurred, and others are left outside a month longer to have a frost or two on them, and then introduced into gentle warmth, they will produce ripe fruit first. Frost sends plants completely to rest, and afterwards they will start freely and readily into growth under favourable conditions. Not only is this the case with Strawberries for early forcing, but with Rhubarb, Seakale, Lily of the Valley, Spiræas, hardy Azaleas, Rhododendrons, Lilacs, and many other plants.—A. NORTHERNER.

THE GARDENIA.

NOTWITHSTANDING what has been written against this popular plant, the great demand for Gardenia blooms at all times, and the high price they fetch, especially at this season, testify to its being a general favourite. With accommodation and forethought exercised in preparing or retarding the plants Gardenia blooms may be had during the six dullest months of the year, and in point of usefulness for decorations of every description they have few equals. Yet in few places do we see Gardenias get the cultural attention which their merits deserve or their requirements demand. Although they are very subject to insects it is quite possible to keep them clean. But seemingly some cultivators are under the impression that Gardenias breed insects spontaneously. This reminds me forcibly of a certain writer some few years ago, and, if I mistake not, in the pages of the *Journal*. To use his own words he said he kept a few mealy bugs on his Vines merely for the sake of experimenting with. But my advice to all who have to deal with either Vines or Gardenias is, if possible, to keep no insects—no not even to experiment upon. However, I have more than once been obliged to experiment with a cheap and effectual insecticide on Gardenias that were badly infested with both scale and mealy bug. This insecticide is petroleum, used at the rate of two wineglasses to the gallon of water. The principal point is in keeping the oil thoroughly incorporated with the water. While the operator is applying the insecticide with a syringe, another man should be mixing the oil and water in a pail with a syringe. The plants if in pots can be laid on their sides on a hand-barrow and thoroughly drenched, allowing the insecticide to remain on the plants for about ten minutes, and then syringe it off with clean water. When Gardenias are planted out we only use one glassful of petroleum to the gallon of water, and never find it to injure the roots.

The Gardenia may be propagated by cuttings at almost any time, and although they are not difficult to strike they often remain callused for a long time before emitting roots. Consequently we prefer striking them in February, the cuttings being made in the usual way, then are inserted singly into thumb pots in a compost of peat and sand. They are then plunged in bottom heat in the propagating pit until they are well rooted, when they may be shifted into 4-inch pots; and if encouraged on with a little bottom heat, by the month of July or August they will be found ready for shifting into a 6-inch pot, which will be large enough for the first season. The pots should be clean and thoroughly drained, with a little moss or sphagnum laid over the crocks. The compost we prefer is equal parts of the best fibry peat and loam, with a little leaf mould, and an 8-inch potful of bonemeal to the barrow-load of soil, and sufficient river sand to keep the whole porous. The loam used should not be of a calcareous nature.

In potting press the soil firmly, and keep the house in which the plants are growing close and moist for a few days until the roots take to the new soil. If properly attended to in watering, pinching, and syringing they will make good bushy plants the first season. But should the object of the cultivator be to have specimen plants in a short time, it is advisable to remove all flower buds the first year and keep the plants growing on in a little bottom heat. Plants intended to bloom should not be pinched after August. In regard to potting established plants there is a diversity of opinion as to when this should be done. Some growers hold that the best time is when the plants commence to set their flower buds, while others are of opinion that they ought to be repotted when blooming ceases, and this is the time we generally cut back all straggling shoots and repot if necessary. When well supplied

with liquid manure, while making their growth and swelling their flower buds, repotting every season may not be found requisite.

The Gardenia delights in a warm moist atmosphere, and should be kept well syringed daily, unless when in bloom, with sufficient light and air, which will solidify the wood, and insure a good set of flower buds.—A. SMITH.

CELERY—SPECIAL VARIETIES.

WHITE PLUME.—Certainly the present time must be admitted as seasonable for expressing opinions respecting some of the many varieties of useful vegetables. White Plume Celery especially has of late come in for a large share of attention, and the opinions are rather condemnatory; but this is probably due to the expectation that the heads would be, as its name suggests, perfect white plumes, requiring no earthing. The first was extremely improbable in my mind, and the latter impractical, at least in our climate, which is damp and subject to severe frosts, and most readers will agree as to how the most perfect White Plume would fare with 16° of frost on Nov. 17th and over 20° on Dec. 7th; yet I must admit that some heads left unearthed as an experiment have proved hardy under such trying circumstances, but are entirely unfit for use in every way, nor do I think it will anywhere, independent of climate, prove of good quality as recommended. I consider it has been wrongly described; treating it, however, as other kinds are treated in all respects it has proved with us a valuable addition, growing from 18 inches to 2 feet high, very stout, well blanched, and solid. In flavour it is not quite equal to Sandringham Dwarf, nor quite so early. For cooking it is equal, if not superior, to any I have grown.

Wright's Giant White does well here. It is especially hardy, much more so than Major Clarke's Solid Red. Tait's Superlative is also an excellent late variety. Williams' Matchless Red is most bardy and a better keeper, but is apt to be rather hollow. Of the other varieties mentioned we have not had an inferior stock for some years. To keep up a constant supply I consider it good policy to grow several varieties, and fully intend to add more of the American next season. I hope I have done justice, and only justice, to White Plume. Your correspondent, "A Thinker," may safely excuse himself of any stubbornness by giving it a trial.—LATHYRUS.

WHITE PLUME CELERY.—Finding this novelty last spring recommended as an acquisition to the kitchen garden, I procured a packet of seed. It was sown in March at the same time as that fine red kind Major Clarke's Solid Red, pricked off the end of April in the open air, and transplanted again in June to its permanent position. I had seen it recommended that planting on the level and not earthing it up would do for it; but while making trenches for our established red kind I thought it as well to make three trenches for the White Plume and earth it up the same; but I also had one row planted in well-manured ground on the level. Altogether over 300 plants of this novelty were planted, but I am sorry to say I am quite disappointed with it. It has not been, I think, one of the best of summers for the well-doing of Celery, but White Plume planted on the level ground and not earthed has been no good at all; not a plant of it will be used, but a few dozens of it from the earthed-up rows have proved useful for cooking, but for salading it is not to be compared with the red variety above named; in fact, I consider it not worth growing at all for that purpose. As to its bardiness, it stood a few degrees of frost very well, but last week's winter weather, with 13° or 14° of frost, appears to have spoilt it, for all exposed leaves look putrid. The leaves of the red Celery look very little the worse for the frost. Major Clarke's Solid Red, if true, is an excellent kind. I usually plant about two thousand of it, and find it keeps well till March and April. When well bleached its crispness and flavour are all that can be desired.—A. HARDING.

STRAY NOTES.

As the year 1885 closes we are looking forward with pleasure to the new year's address, and now is a fitting opportunity to acknowledge what a great amount of pleasure, instruction, and gratification our *Journal* has afforded me, and how eagerly its contents are read. Certainly the *Journal* has progressed and kept pace with the times, and this is saying much in these days of enterprise. While we still keep the old standard writers the new and younger ones are not wanting in spirit, as their contributions show. To my mind the *Journal* is a storehouse of information useful for all. Let me specially commend to my younger brethren the several articles that have appeared on their behalf.

Turning to our garden products, it is remarkable what an increase has taken place in the consumption and culture of the Tomato. The varieties are much too numerous, or at least so-called varieties, and I would advise growers when they get a good suitable variety to select their own seed. The Vine has come in for a good share of attention, and quite a revolution has taken place here, more especially in the late varieties. The troughs and bottles are going to do away with very early forcing, and rightly, too, when good late Grapes can be put on the table up to the end of April or the beginning of May, Grapes that the Black Hamburgh cannot equal for flavour. I shall never forget the Grapes at Longleat which I had the pleasure of seeing in November. The Muscats were of course the sight, because without disparaging the good quality of the Alicante, Lady Downe's, and Mrs. Pince, they were not so fine in comparison. All the more honour to Mr. Pratt for keeping the Muscats to the front

I now also thank Mr. Taylor for his very hearty welcome and for his useful hints.

The allotment question has found a place in the Journal, and I have pleasure in stating that in this village we have some two dozen allotments, which give useful employment to a number of intelligent labourers; but I have had several reliable statements made to me that there is very little profit attending it, if labour and everything is to be paid. Large allotments would be an evil, not only to the man but also to the employer.—STEPHEN CASTLE.

FERNS—THEIR HISTORY AND HABITATS.

[A Paper read before the Paxton Society by Mr. J. G. Newsham of Sheffield.]

(Continued from page 565.)

To give you a descriptive account of our British Ferns I should occupy a large space, and perhaps prove rather tedious. I have classified them into groups according to their strata. Each separate British species has its own birthplace, or supposed birthplace, and almost any of the authors on Ferns will give the place, date, name of the discoverer, and in fact the whole pedigree of the plant. I am not aware that any attempt has been hitherto made to arrange them into stratagorical groups—if I may be allowed to coin a word. In the first place it will be evident that the main features governing the localities which Ferns inhabit are moisture, shade, protection from cutting winds, and, generally speaking, drainage. There are exceptions to this rule, but the number of Ferns which can bear exposure, and of those which inhabit our bogs and marshy swamps, are so few that the exceptions in this case will prove the rule. The Ferns who dwell in high places and revel in the free mountain air, although apparently exposed, receive more protection from cutting winds than a casual observer would suppose. The deep fissures and crevices of rocks afford them a far greater amount of protection than they appear to possess. Moisture, too, is even highly essential to the well-being of these mountaineers. Amateurs and professionals, too, in many instances omit to observe that this is so, and consequently lose many plants of this class by the dryness of the atmosphere which surrounds them under cultivation. The heavy dews and passing clouds at high elevations are continually feeding such plants with an abundance of moisture.

However, I am perfectly justified in asserting that the real home of our Ferns—speaking generally—is in localities abounding in moisture, places hidden from the scorching rays of the sun—the shaded mountain slope, the banks of the rushing stream, the quiet glen, the deep ravine, the tree-protected rocks, the hollowed caves by the sea, where the action of the waters have for centuries gone formed suitable homes for the growth of many of our maritime plants, and to these localities we must ever look for the most successful results in the gathering of Ferns.

One accustomed to observe such habitats, and who has studiously observed the relations which exist between localities and varieties, would tell you that the strata all have their special productions. I know that the question has been raised by pteridologists as to whether the strata possess any virtue in producing or fostering the various species, and I do not for one moment wonder at this, because we invariably find Ferns which are said to be indigenous to one locality growing upon rocks or in localities of quite a different nature. For example, the Hart's Tongue (*Scolopendrium vulgare*), the Brake Fern (*Pteris aquilina*), *Lastrea dilatata*, commonly known as the Male Fern, and a few others which I could name appear to have no specific home. The *Scolopendrium vulgare* is considered by some authors to be strictly a calcareous plant, but how often is it found upon sandstone, ironstone, and other formations? The same remarkable feature exists with reference to the common Polypody (*Polypodium vulgare*). This in my estimation may be accounted for in various ways, more especially from the fact that the ripened spores have been wafted by winds or carried by streams, and have found lodging upon substances which have contributed to their propagation and development in the shape of rich soil favourably located. Spores when once ripened may be propagated in entirely different soils to that in which it originated, but the ultimate results fall far short in foreign substances. My opinion is that the natural home of a Fern is that in which it loves to sport. I have found *Scolopendrium vulgare* growing upon a slate formation, but upon examination of the locality for miles, in which I found it growing, no other traces of that Fern could be found. Consequently I considered it in that case to be an alien, and I have in many instances noticed similar illustrations of our most conspicuous truants.

I give it upon my own authority, based upon my own con-

victions, that a Fern in its native element must be one that is watered with that peculiar water which issues from the strata which originated its production.

The most prolific habitats, referring to the strata, are limestone and red sandstone. Slate formation stands inevitably low in production, although in suitable soil, we find many varieties growing in a healthy condition. Of the forty-eight British Ferns, we have twenty-one rock Ferns, twenty-one which inhabit rich soils, and six marsh Ferns. Out of the twenty-one who are indigenous to decayed vegetable matter I make a sub-division, and select thirteen of that number which are watered by the various strata. Thus we possess eight species only which are entirely at home in rich decayed leaf mould or loam. Of the twenty rock Ferns we have nine limestone, nine sandstone, and three slate. Of the thirteen which are to some extent dependant upon the strata, we have five on the lime and eight upon the sandstone formation. This in the total shows—Limestone, fourteen; sandstone, seventeen; slate, three; and marsh Ferns six; rich decayed vegetable matter, eight. Total, forty-eight.

CULTURE OF FERNS.

The popularity which Ferns command is attributable to their adaptability for almost all positions and situations. The treatment required by them is simple, and is within the power of all. They may be termed good-natured plants—plants designed to bear a large amount of neglect and cruel treatment before they actually succumb. Hence it is that we find them almost everywhere; in the windows of our cottages, upon waste patches of ground, upon stony and ill-fed rockwork, looking miserably poor, and to a practised eye positively famishing, or grown in cases and under bell shades, or in various other ways, affording small pleasure to the owner, even if a few delicate yet green fronds remain to indicate the beauty which they once possessed. Often have I looked upon such plants with sorrow and regret. It must be that the owners of such plants are not ignorant of their simplest requirements, but positively careless and indifferent. Then, again, we often find Ferns growing under quite different circumstances, having all the care and attention which such persons can bestow, perfectly clean and tastefully arranged, yet in poor health, and in this weakly condition they exist for long periods, affording but little satisfaction. We require to have a love for the plants we grow, and unless this can be done it would be well to abandon the attempt. Let me ask all who may have a desire to follow the cultivation of Ferns to remember that old proverb, or maxim “Whatever thine hand findeth to do, do it with thy might.”

We see many methods adopted, some in baskets suspended in windows, others in old walls, others on rockwork in the open air, or in greenhouses, vineries, or ferneries specially constructed, boxes on window sills, while by far the greater majority of amateur growers prefer the bell shade or Wardian case. Taking all these methods into account, they may be classified as Ferns protected and unprotected. I will endeavour to deal with both, and so far as my own experience bids me, render such assistance as I am able. Dealing first with Ferns unprotected—that is, grown in the open air, it will be quite obvious that in removing Ferns from their natural home, and bringing them under the hand of a cultivator, many dangers will be encountered which may be surmounted. Two of the main features to be observed for an outdoor fernery are position and formation. That Ferns love shade is an acknowledged fact. They will, it is true, for a time exist under exposure, yet under such circumstances they are dwarfed, and never even give a glimpse of their bright and beautiful nature, being devoid of all interest, robbed of their charms, and the grower cheated of his expected pleasure. Let the fernery most certainly have the best protection from the scorching rays of the sun, and from cutting or drying winds. Both are equally destructive to root and branch alike, drying up the former and robbing the latter of its natural gracefulness and colour. By a due observance of the main or essential habits of the Ferns you wish to grow, failure may be easily prevented.

(To be continued.)

CANKER IN FRUIT TREES.

THE discussion on the above subject must be interesting to all growers of fruit, especially those who earn their living by so doing, and any discoveries of the cause of this mysterious disease are most welcome, especially if they afford a prospect of cure. The directions sometimes given for curing the disease, like those given for planting fruit trees, although, no doubt, applicable on a small scale, must often cause a smile on the face of those who grow for market, as following them would simply mean ruin.

I have some young Pear trees which developed canker after a severe winter made fresh growth after a hot summer (the cankered part being

cut off), and again cankered after the next winter. I have also some young Apple trees which were healthy until the hot summer of 1884, after which they were badly cankered, and more so after this late hot summer. The first is quite a different-looking disease to the last, and appears to be caused by rupture of the sap vessels by frost. The last sort of canker I attribute to the drought sending the roots down deep after moisture into an unfavourable subsoil, and the disease eats right into the wood. Our top soil is a rich fertile loam interspersed with *débris* of the limestone called Kentish rag. The subsoil is red and clayey, likewise full of stones, and the natural drainage is good. The subsoil I believe contains a good deal of iron, which I regard as a cause of canker, and which opinion is corroborated by the interesting information given by "Thinker" on page 536. This subsoil is called locally "red-pin." Since reading in the Journal the observation of the late "Single-handed," that the acids always present in humus act as solvents on the mineral plant-food present, and when they reach the iron, which binds some subsoils into pans, it is dissolved, and the pan put an end to," the manures which I have applied have been principally those which furnish humus, and which always attract and hold water best of all soil ingredients, and would therefore tend to keep the roots from going into the subsoil after water. It is a fact that the red soil in the neighbourhood is deficient in humus, and fruit trees growing in it are more subject to canker, while the opposite is the case with the more loamy soil. Varieties which flourish in the latter, even if full of springs, are killed with canker in the former even where there is good natural drainage. The deduction is that much iron in the soil causes canker, and that a plentiful application of the humus will cause the iron to dissolve and get washed deep down from the roots, but I have not had sufficient time to prove it on my own ground.

I remember Mr. Bunyard telling me that a gentleman cured canker by a plentiful application of wood ashes round the roots. I have often wondered what was the reason of it. First, if it was due to the large quantity of potash they contain, and either it or phosphorus or other mineral supplying the tree with some element needed to sustain a healthy growth; humus or decayed vegetation would also mean plenty of potash and similar minerals, only unburnt. Second, if it was due to the action of these minerals in dissolving iron in the soil; or, third, if it simply caused the production of surface roots in the good soil, but this would not bring the lower roots up. Perhaps Mr. Bunyard can give us some further information as to whether the tree or trees were dug up and replanted, &c.—WALTER KRUSE, *Maidstone*.

MR. HIAM has done well to draw special attention to this subject, which, in spite of our professed improvements in fruit culture, still appears to be rather on the increase than otherwise. He may have somewhat overshot the mark in ascribing this malady solely to insect agency; notwithstanding, it is highly probable that a very large per-centage of the cases classed as canker have originated from and increased by insect ravages only. In support of this belief I knew of one special and striking instance where an old, long-neglected, and much-cankered orchard of Apple trees was completely restored to health by thorough periodical dressings over stems and branches, and where the roots received no attention beyond a light annual surface-dressing with well-decomposed manure. I should say, however, that the soil, if not the situation, was considered favourable to their growth, and so rapid was their improvement that in a few years afterwards scarcely a trace of the disease could be discovered. It may be said, indeed it is stated in your last week's impression (page 529) that such cases "are not canker, as the term is generally understood." Such may possibly be so, but to discriminate between them and say which is real canker engendered by internal ailment, and which is produced by external agency, be it animal, atmospherical, or other cause, is indeed difficult to decide. There cannot be a doubt, however, but that in some unsuitable situations and soils canker is exceedingly prevalent, and the difficulty, in some instances the impossibility, effecting a cure, or of even checking its increase, seems to point conclusively to other than insect agency as the cause of the evil.

That some few kinds of soil seem to exert a prejudicial effect on fruit trees by inducing canker and disease some time after they have been planted therein cannot be disputed, but it is not improbable that this evil is often more due to unsuitability of position rather than to any hurtful chemical constituents of the soil. By this I mean that if planted in the same kind of soil, but in a drier, warmer, and more elevated position, the trees would in all probability grow less luxuriantly and continue altogether free from the disease.

It is this over-luxuriant growth, enforced by too damp positions and by too stimulating treatment, as well as by the frequent mutilation, sometimes mis-called pruning, that we have most to fear. This strong growth is for a time very promising, and will perhaps continue to be so as long as favourable springs and, what is still more important, suitable autumns for thoroughly ripening it continue, but the first unfavourable autumn, succeeded by a severe winter or spring, will produce such evil results as will quickly and permanently develop into canker in almost every branch, except perhaps on a few trees possessing hardier constitutions. How plainly does the instance mentioned by Mr. Warner (at page 540) of one variety of Apple being free from canker while another, although growing on the same stem, is diseased, point to this conclusion.

Could we but impart the constitutions of Cox's Orange Pippin and Wellington to Ribston and Golden Pippin, or that of Beurré de Capiaumont and Dunmore Pears to Glou Morceau and Easter Beurré, we should have but little to complain of in respect to canker, even in this unsuitable and changeable climate. Some few kinds of soil may, without the presence

of any other predisposing cause, possibly produce canker, but they are, I think, few indeed. That soil highly impregnated with iron may and sometimes does have an injurious effect on Apple trees in some positions is also possible, an instance of which I believe I once saw; but when these trees were removed to a higher position a short distance away, where the soil was equally impregnated with iron, and where they quickly outgrew the disease and afterwards continued free from it, I was compelled to change my belief. In respect to the canker or gumming peculiar to many kinds of stone fruits referred to by "An Old Gardener" (page 529), whatever may be the precise physiological disarrangement in the tree which engenders it seems likely to be veiled in mystery, but there can be no doubt whatever that unsuitability of climate is the main predisposing cause. When this can be remedied and other details of cultivation are reasonably and judiciously carried out, canker or gumming almost wholly disappears, thus showing most plainly that unsuitable climate, and not soil nor insects, is the worst factor in producing canker.—T. CHALLIS.

COVERING SEAKALE CROWNS.

IN the "Work for the Week," page 525, it is recommended that the soil from between lines of Seakale be put upon Seakale crowns to bleach them. I have found that where soil is used alone, and is at all adhesive, it cripples and sometimes breaks the Kale in its struggle to get through the soil. To avoid this we mix coal ashes, old leaf-soil, and sometimes seasand with the soil. Either of these materials will do to lighten the soil, but having leaf soil and seasand at hand, we find useful for working into the soil for future vegetable crops.

A few words as to our practice may not be out of place at this season, as where this vegetable is appreciated most gardeners are now busy taking up the old crowns for forcing. In taking up the plants many of the large roots will be broken off, and others that are not necessary are broken as the work of lifting proceeds; these are all saved, and covered either with sand or soil until a wet or unsuitable day for outdoor work comes; they are then taken to house and made into cuttings about 4 inches in length, the top being cut quite flat, and bottom slanting for the purpose of knowing the top from bottom, as we find that when cuttings are planted the wrong end up the crown starts from the bottom, consequently is some time reaching the surface of the soil, and is very weak. After the cuttings are made they are again covered with soil or sand to keep them fresh until a suitable piece of ground is made ready in early spring by deep trenching, and at the same time working in well-decayed manure, seaweed, and sand. A line is then put down in centre of double line; we make holes with dibber on both sides of the line at 6 inches from it, and alternate. These double lines are 3½ feet apart, thus giving us ample room to mix the material above described with the stiff soil to put on the crowns, which are covered 1 foot deep. In this way we get very fine heads, many 1 lb. weight, from spring cuttings, and of good quality. Our early supply is taken up in the usual way, and either forced on slight hotbeds of leaves, or in boxes or pots under stages of any heated house, but our best quality Kale is got by covering where it grew.—W. O., *Fota Island, Cork*.

NOTES ON CHRYSANTHEMUMS.

AMONG gardeners no other flower, not even excepting the Rose, can lay claim to such popularity as the Chrysanthemum, and every season adds hundreds to the lists of growers. The Chrysanthemum season serves to bridge over some of the months which at one time were usually the duller in the year.

The season of 1885 cannot by any means be said to have been highly favourable to the production of high-class blooms in great abundance, and never before probably were there so many disappointments. The excessive heat of the summer, coupled perhaps with a scarcity of water, left its mark on great numbers of plants, and then to make matters worse we in the south experienced severe frosts before the greater portion of the plants were housed. This appeared to have been most injurious to the very forward and latest buds. The effect of first the hot weather and then the early frosts was less apparent, I might say was unobservable, in the classes for cut blooms, but the specimen-trained plants, as far as my experience goes, told a very different tale, many being shown that were very poor indeed. Only a few being grown, the exhibitors had no choice in the matter; but plants to provide cut blooms being more numerous much less difficulty was experienced in selecting the required numbers. The frost, however, quite spoilt the chances of several intending exhibitors, some of whom I hope to see well to the front next season. A friend in the extreme north of England informs me that their plants were uninjured by frosts, but we dwellers in the "sunny south" would be surprised to hear that the bulk of his Chrysanthemums were not yet at their best, and as this was about December 10th this grower should put in appearance at the January Show of the National Chrysanthemum Society. Chrysanthemum shows do not appear to be at all numerous in the northern counties, but there is, I should imagine, no reason why there should not be many of them, only they must be held in December instead of November.

There were naturally plenty of disappointed exhibitors in this district, but as a rule I heard but little grumbling at the awards of the judges. The greatest bother was about synonyms being included where distinct varieties are stipulated for, while doubt existed in some quarters as to the sections to which some varieties rightly belonged. I was somewhat surprised to find that Mr. Hobbs, one of the best known Bristol amateur exhibitors, should have felt justified in including Empress of India and Mrs. Cunningham in a stand of twenty-four distinct large-flowered varie-

ties; but those who are acquainted with the veteran grower will agree with me that nothing unfair was contemplated. Mr. Hobbs evidently considers them distinct, and he acted accordingly. At Taunton, where I had the assistance of Mr. Lock in judging the numerous well-filled classes for cut blooms, we were "taken to task" by an experienced exhibitor for not disqualifying a stand in which a Japanese Anemone was included with the ordinary Japanese sorts. In another class, that for reflexed varieties, *Triomphe du Nord* and, I think, *Salteri* were included, and these again we did not disqualify any more than we did the stands of Anemone-flowered that included Japanese Anemones. No; I hold that unless the rules expressly forbid the inclusion of Japanese sorts in certain classes, the judges are not justified in disqualifying where they are so included. If hybrids are admitted in one class, why not in another? and, unless forbidden, Japanese Anemones have as much right to be shown with the ordinary Japanese sorts as they have with the old Anemone-flowered. Whether this will meet with the approval of such experts as Mr. Molyneux, Mr. Orchard, and others remains to be seen; but I may add that Mr. Lock has had advice (not from a lawyer though), and we are supported in our decision. Let me impress on the framers of schedules to be very careful in the wording of certain rules, and this will prevent much future dissension. The definition in every case should be clear, especially as regards the admittance or non-admittance of Japanese hybrids in Japanese and other classes, as well as hybrid Pompons in the classes nominally for pompons. Supposing the National Society will issue a fresh catalogue. Why not take their arrangement of sections as a guide? further adding that the synonyms bracketed must be abided by; then if copies of this official catalogue are placed in the hands of the judges no mistakes need be made in the matter. This may not be so imperative in the districts where the *Obrysanthemum* is so well known, but the case is very different when we leave these centres, and what we have to consider are those parts where societies are newly formed.

It is somewhat surprising how few novelties there are in the incurved section, those few that are added to the list being principally sports. The most noteworthy exception is *Jeanne d'Arc*, and this grand sort soon attained to the front rank. I found the crown buds of this variety were too early, and several fine blooms were of no service whatever. Much patience has to be exercised in dressing the blooms owing to the petals being thin in substance and very numerous. *Bendigo* or *Mabel Ward* was disappointing at first, but the crown buds may have been injured. Latterly we have cut lovely blooms resulting from terminals, and the same remark applies to *Jardin des Plantes*, crown buds in this case being followed by large blooms with split centres. *Lord Wolsley* still proves a trustworthy sport, and is quite distinct from its parent *Prince Alfred*. *Queen of England* was shown grandly at Bath, and if Messrs. Carter's bronze sport from it is fixed and possesses the good qualities of its parent it will prove a grand acquisition. *Golden Queen of England* gave us some immense blooms, but they would not incurve properly, and I believe many have experienced the same difficulty with it. The best bloom I have yet seen of it was shown at Yeovil by the Messrs. Drover. *Lord Alcester* is deservedly most popular, but this and *Golden Empress of India* proved very "tricky" this season, many of the largest blooms developing several centres, "all the dressing in the world" failing to whip them into shape. I thought we had overfed them, but when I saw others in the same predicament, and when Mr. Molyneux rather doubted if I had hit upon the right solution of the difficulty, a fresh cause had to be found. Was it the hot weather? was it the frosts? or what was the cause, eh, Mr. Molyneux? I had hoped to have included quite a new sort in what few stands of incurved I exhibited, but the frost upset my calculations. This was none other than an incurved sport from Mrs. Forsyth, and which I have dubbed "*John Bradner*," this noted Bristol grower having discovered and fixed this sport, but why he has not pushed it I cannot explain. It exactly resembles Mrs. Forsyth in its growth, the colour of the flower being also the same, but the somewhat imperfect blooms that I had incurved beautifully, and I still hope to see Mr. Bradner derive some benefit from its introduction.

Japanese sorts, beautiful as the majority undoubtedly are, are really becoming too plentiful, the lists of novelties being quite bewildering. Luckily, our "headquarters men," notably Mr. L. Castle, are well able to discover and point out which are the best, and this serves to guide many of us in our selections. At one time I purchased certificated varieties and others with glowing descriptions. These included *Salteri*, M. *Henri Jacotot*, *Roseum superbum*, M. *Boyer*, *Comet*, *Gloria Solis*, and M. *Moussillac*, but none of these proved of any service for exhibition purposes, being either too early or too small, while many of the sorts I passed over in favour of those just mentioned have been popular with exhibitors, and this, to say the least, was rather aggravating. Of the sorts flowered with us for the first time this season I give the preference to *Val d'Andorre*, *Madame de Sevin*, *Duchess of Albany* (Jackson's), M. *Ardene*, and *Belle Paule*. The latter I grew on the recommendation of Mr. Mease, who had already given it a trial, and on the whole I consider the most distinct and most beautiful novelty of recent introduction. It was somewhat late, crown buds only being expanded in time for exhibition, but blooms resulting from terminal buds were the most attractive.

Cullingfordi I have not yet grown, but from what I have seen of it should say that it is a valuable and most beautiful addition to the reflexed section, where I hope it will be definitely quartered. All the Japanese Anemone-flowered are most attractive, but unless they are divided from the old Anemone-flowered varieties the latter will be at a decided disadvantage, and will soon be lost to the exhibition table. In a few instances Pompons have been very prettily shown, being bunched up with a little foliage intermingled. As a rule they present a very insignificant appear-

ance not at all pleasing to their by no means limited number of admirers. Why cannot they be shown in the same manner as single Dahlias, or at any rate in good-sized bunches, disbudding being permitted in order to have them at their best?

The mania for a collection of a large number of varieties is still rampant, and that, too, in spite of the frequent warnings against it expressed by those who well know how great a mistake this is, unless it happens that the cultivator is not ambitious to figure conspicuously at the shows. The inexperienced seem to imagine that the more sorts they can collect the better chance they have of winning the prizes, whereas quite the contrary holds good. Those who read the various reports of shows will observe that much the same varieties are to be found in the prize-winning stands throughout, and it is these that should be preferred, growing as many plants of each as circumstances will permit. The advantages attending this practice will be obvious enough when show time arrives, as the grower will then have plenty to select from, whereas when only one or two plants are grown the blooms on these may be too early or too late, or from various causes may not be up to exhibition form.—W. IGGULDEN.

JUDGING FRUITS.

THE discussion on judging which is being carried on in these columns will lead to some definite result, I have no doubt, or a great deal of time and thought will have been wasted. I wish to offer my quota on the subject, especially in support of what I advanced in your issues of September 10th and 17th. I also have to notice the slight criticism to which it has been subjected, partly complimentary and partly adverse, but so little of it as to suggest the notion that after all things are not so bad as to require any change in the system of judging, or any necessity to formulate a fixed scale of values for the various exhibits in mixed collections. Possibly there are some who write on this who are fussy individuals, always dissatisfied with things as they are, or they may be disappointed exhibitors endeavouring to cover defeat by the advance of a few imaginary irregularities, yet many of your able correspondents have engaged the subject. If we allow a fair proportion of them to be earnest writers, anxious to have anomalies put right, how many might they represent anxious and desirous of seeing correct rules laid down, and antiquated notions put aside, but who have no desire to ventilate their ideas publicly. That there are many ways of procedure in awarding prizes no one will deny, and some of them are very strange. No further back than September last, at one of the most prominent shows in Scotland, the plan pursued throughout the collections of fruit, as explained to me by one of the judges in that department, was this—In the first-prize collection of eight varieties three points were given to a dish of *Madresfield Court* Grapes, supposed to be the best of its kind ever shown. The same number to each of two dishes of Peaches, the same to a dish of *Nectarines*, a like number to a dish of fair *Green Gage* Plums, two to a dish of *Black* *Hamburgh* Grapes, two to a dish of *Apricots*, the remaining dish, *Figs*, going for nothing. Those who followed this three-point rule are the most experienced judges, and probably the best horticulturists in North Britain. No doubt they would be able to give a satisfactory explanation of the plan they adopted, although it is difficult to perceive how. I fail to see how this mode could be satisfactorily performed, unless the whole opposing dishes were the same varieties, then every collection would share alike. In this case all the varieties in the three-prize collections were different, except two or three.

I would now refer to the few remarks of "*A Thinker*" on the system proposed on page 221. He attributes mistakes in judging to various causes (page 313), all of which may have a tendency in that direction, but which are superficial and could be easily remedied. The mistakes I consider of most importance arise on the part of the exhibitor through miscalculation, and misapplication on the part of the judge. If exhibitors were fully alive to the value the varieties would receive in competition, they would know what to produce with any chance of success, then their place in the prize list would be determined by the degree of perfection to which they had been brought. Then, again, a fixed value for the different sorts should be established in order that a proper estimate of worth might be applied in accordance with the respective merits of each, thus making judging more uniform and simplifying the adjudicators' labours.

I will now refer to the objection taken to the system mentioned above as being too elaborate and taking up too much time. The time wasted would be less than your correspondent seems to imagine, as it would be necessary to apply it only in close competition. And this is where the disputes come in, and where men are mystified and led to exclaim, "Well, I don't see how this or that has been preferred." Here the cards referred to would come in with full details to unravel the mystery. No necessity for publication. Moreover, the judges ought not to object to the results of their labours being exposed, but rather favour the opportunity afforded to show the faith that is in them, and nullify the criticism to which they are often subjected, as on the occasion of a great show held a few years ago north of the Tweed, where the critics were dissatisfied with the awards in the big collection of Grapes, supposing that the judges had been deceived with the large bunches in the grey of the morning, but that if judging had been an hour later the decision would have been different. I must still adhere to the declaration of the non-payment of judges until it becomes a profession; then I would say the better pay the better service we might expect, as the selection is generally made from the ranks of head gardeners, whose pay is never withheld when absent from home duty. The labour of the servant ought to be

and is considered by the employer as part of a contribution towards the promotion of high-class horticulture.

I am glad to be supported by "W. A." in an endeavour to supplant all rough-and-ready rule-of-thumb methods of judging in an enlightened and more consistent style to which all horticulturists could subscribe. Your correspondent disagrees with me only in the value of the mark, and the manner in which the figures are finally arranged. Simply changing the terms would meet his view in the one case. As to the other, the rule which guides the advance of our arithmetical notations in fractions, however convenient, must not interfere with any arrangement in fixing an estimate of value between sorts or varieties. I grant the system proposed may not be complete, but any modification of it that would admit of more points being allowed, and correct values given in collections, would meet the difficulty, unless they were to be judged according to evenness over the whole, which should not be, but let every variety stand or fall by its own merit.—W. WILLIAMSON.

In reading the "Committee side" remarks of Mr. T. Challis on this subject at page 565, I confess to being astounded at his teaching regarding the relative positions of "Judges and Committees of Shows," inasmuch as he gives to the latter a power which it is neither entitled to by law nor qualification—namely, that of altering the awards of the Judges. The latter, Mr. Challis says, are, like other men, fallible; but does he mean to say that the gentlemen forming the Committees of Shows, who are not always experts, are less fallible than the experts selected by them on account of their position and known ability to perform the duties of adjudicators? He says the Judges are the servants of the Committee. Nothing of the kind. They only accept an engagement to make the awards at the Show, and they do so to the best of their ability. Neither the Committee nor its officials have any voice whatever in determining the awards, and these awards, it is stated in the schedules of Shows, "shall be final." Therefore the Committee, by its own printed rule, has no power whatever to disturb the awards of its Judges, nor to indicate to them the manner in which they should make the said awards. Yet, in the face of this fact, Mr. Challis tells the readers of the *Journal of Horticulture* that the Committee is "morally and legally" justified in correcting (?) any mistakes which in its opinion have been made by the Judges. Morally and legally the Committee has no right, even if it had the capacity, to interfere with decisions of the Judges. Were it otherwise, engaging and paying Judges to make awards at Shows would be a mere farce! However, it is very rare that a case of this sort happens, but when there is one, and a gardener of Mr. Challis's position endeavours to justify the action of the Committee, it is therefore necessary to show that Committees, in point of fact, do not possess the power if they have the competency (?) to deal with such matters. However, the Committee of a Show would be acting within its right to draw the attention of the Judges there and then to any awards respecting which protests had reached it. Then the Show Committee would hear what the Judges had to say, and should act accordingly. But, on the other hand, it should take no notice whatever of the opinions gratuitously given by "irresponsible" individuals on such occasions.—W. S.

LONDON'S LESSER OPEN SPACES—THEIR TREES AND PLANTS.—No. 6.

WALKING along modern Westminster, a place, we might say, unsurpassed by any other in the British islands for historic interest, not even by London City, we can hardly fancy to ourselves it was ever an island. Yet such was the fact, and on examination we can manage to trace out its shape, for there was a stream, extant not many centuries ago, called "Long Ditch," which ran out of the Thames near the Abbey, and ended about Tothill Street, but which once, doubtless, by a curve joined the ponds of St. James's Park. That park gives us now water extending almost to Buckingham Gate, and we have only to suppose in the olden time that in the space between the park and the basin of the Grosvenor Canal (now Victoria Station) was intersected by a small, or perhaps a large, stream, and there we have the outline of the primitive Isle of Thorney, a spot much overgrown with Briars and Thorns. These were probably Brambles for the most part, some Blackthorns amongst them, it may be, and we shall have difficulty in finding representatives of these in Westminster now. It is seldom one sees the Blackthorn or Sloe in a London garden, yet I think this is a species that would grow fairly well, and if not within a very smoky district put forth its flowers which herald spring by their early display upon the nearly leafless branches. The Spindle Tree (*Euonymus europæus*), another May-flowering shrub, is also a species that should be grown about the metropolis; one of its recommendations, so far as appearance goes, is the beautiful tints it exhibits ere the fall of the leaf. The fruit, however, though ornamental, must be avoided, being somewhat poisonous.

I question whether the Hawthorn was one of the plants that formerly flourished in the Isle of Thorney, though Westminster can show us a few of rather sickly growth. This shrub, or tree, in London districts seldom attains to any size, and we do not see those fine specimens of gnarled and twisted Hawthorns that are noticeable in many parks and woods. It was for some time doubtful to me why the Hawthorn planted about London, after growing several years, gradually falls off and either dies or becomes stunted; at least, this frequently happens. At first I thought the atmosphere of the town was unfavourable, hurrying it perhaps too early into leaf, but I conclude now that it is generally the injurious result of prolific caterpillar foes. This and other shrubs often get little atten-

tion from the gardener, who is busy about his flower beds, and so the Hawthorn is infested with swarms of caterpillars, as, for instance, with those of the winter moth, the small ermine, and the vapourer, which exhaust its strength during the summer. Close to the Westminster Guildhall and opposite New Palace Yard there is a piece of enclosed ground, graced with a statue of Canning, and which contains some good-sized Sycamores and Elms along its edges, but the centre is filled up with a straggling company of badly shaped Hawthorns, Lilacs, and Limes, that must have been planted some years ago, and since, apparently, left to struggle for life as best they might. The Metropolitan Bonlevard and Public Gardens Association are endeavouring to get this space made free to the public, and, this done, I should advise the removal of most of the shrubs and half-grown trees now there and the planting of a few more suitable, while one side flanked by a wall could have creepers or a rockery to form a background.

Under the shadow of the venerable Abbey and nearer the river is the churchyard of St. Margaret's, not so many years ago a moist, melancholy, unwholesome spot, shunned by the pedestrian. It has been improved of late, some Sycamores planted along its sides, and the area, after levelling, has been laid down with grass—a better plan certainly, considering its position and dimensions, than attempting flower beds. Scattered round this churchyard, or occupying some of the angles of the Abbey, are some larger Sycamores. These, however, would not be older, I judge, than about fifty years. It was curious to see, nestling in the sheltered nooks under the Abbey walls, patches of the familiar Chickweed of fields and lanes, supplying to the town sparrows green food when they can obtain but few seeds or insects.

Dean's Yard, to which access is obtained under an archway from Broad Sanctuary, is an open space which is likely to be missed by anyone who is a stranger to the locality; yet it is of larger extent than the name might suggest, and the railed ground in its centre has long been used by the Westminster scholars for football and other sports. This is not particularly beneficial to the grass, nor to the Limes and Sycamores planted round the sides of the square in an irregular fashion; these also suffer maltreatment from the juveniles who congregate outside at times. In a corner of Dean's Yard, amongst the houses, a very large Sycamore stands alone, which has doubtless a history worth telling could one unravel it. An attempt has been made to form a bank of plants behind its venerable trunk, but the position is against their growth, though window-gardening is carried on successfully at several of the houses in the Yard. Curiosity or a kindly interest brings some persons to Dean's Yard from a distance to see the annual exhibition of plants cultivated by the poorer class chiefly in the Westminster district. These are somewhat assisted by the distribution of roots or cuttings which is made in the autumn, when the flower beds are cleared in the parks and some public gardens, but occasionally I have noticed this is deferred too long, and then the plants given away are partially spoilt, because they are touched by early frosts.

On the bank of the Thames, offering an agreeable prospect, and a blow off the water to invigorate the lungs, is an open space called Victoria Tower Gardens, not very extensive, yet one might have supposed it would have had its visitors at all hours of the day, drawn from the thickly populated streets of Westminster. True, the grass plats in the centre are forbidden to the public, but there are broad paths and seats beside them free to everybody, yet when I entered not a soul was there, nor did man, woman, or child afterwards appear. At the gate there is a box for the caretaker, and he sat therein sleeping "the sleep of the just," perhaps from too heavy a dinner, or wearied with the dullness of his duties. One of these is to prohibit "shouting," as appears by the table of regulations—not a frequent offence, seemingly. Nothing has been planted to intercept the river view, but on the east side of the gardens is a belt of shrubs separating this space from a less enclosure belonging to the Houses of Parliament. Some are evergreens, some deciduous shrubs, and being sheltered from the colder winds they are in a good condition, though set in that promiscuous style frequently observable in public gardens. As no access is permitted to the grass plats, a few shrubs that would look cheerful at all seasons might be placed here and there; but I am a hearty advocate of allowing the youngsters the pleasures of the turf, under supervision, where it can be managed, or at least a part of the space under grass might be free to all, while the growth was protected from the tread in other portions. It should be added that Vincent Square, Westminster, is another and larger open space, also a playground of the Westminster boys, and with an area of grass that might be turned to much better account than its present limited usage.

A district called South Belgravia, where early in the present century there were reedy fields and gardens devoted to the culture of succulent vegetables, amongst streets of uninviting aspect, has a few squares, which may be dismissed briefly, as they are not as yet open spaces benefiting others than the immediate residents, except in so far as they tend to purify the atmosphere by their trees and plants. Eccleston Square is about four acres, Warwick Square three acres, the oblong St. George's is a little larger than these. I think they have some well-grown Limes and Sycamores, but not of any size, the time since planting does not allow of that. Willows and Poplars, which would thrive here, are unfrequent, and their shrubs are of the usual London type, the Privet and Lilac being much favoured.—J. R. S. C.

NARCISSUS BULBOCODIUM VAR. MONOPHYLLUS.

THIS beautiful little Hoop Petticoat Narciss is one of the earliest flowering forms in cultivation, and worthy the attention of all who

admire this interesting race of plants. It is white counterpart of the well-known yellow type, but has very slender leaves like *N. tenuifolius*, though not so long, and usually only one is produced by each bulb. It was introduced from Algiers to Kew by Col. Playfair, and flowers were produced in January, 1870. It is, however, considered by some writers to be identical with one of the four varieties known to Parkinson, one of which is described as "The White Bastard Rush Daffodil or Jonquilla." It has also been named *Corbularia cantabrica*, which Mr. Burbidge says "Originated from its having been grown about 1588 by a 'Master Nicola Benson, sometime of King's College in Cambridge,' as noted by Gerard."

Fig. 87.—*Narcissus Bulbocodium* var. *monophyllus*.

It is a charming plant, its flowers possessing a delicate and most agreeable fragrance.

REVIEW OF BOOK.

Fruits and Fruit Trees, Home and Foreign. By LEO H. GRINDON. Manchester: Palmer & Howe, Princess Street; and London: Simpkin Marshall & Co.

THIS work, as the author states in the preface, "claims to be no more than an amateur's contribution to the literature of the very large and varied subject," and as such it will be welcome to many who are already familiar with Mr. Grindon's free and agreeable style of writing. The book deals chiefly with the history and origin of the principal cultivated fruits, and in this respect it might be compared to a popular rendering of M. Alphonse Decandolle's admirable work on "The Origin of Cultivated Plants." Much statistical matter is added respecting the importation of foreign fruits, and of English fruits, are given short lists of varieties generally useful for cultivation. Perhaps this may be regarded as the least satisfactory portion of the work, for, though the author acknowledges the assistance of some noted fruit-growers in preparing it, yet there are some varieties named that are not worthy of a place in small collections. For instance, under the list of Vines, at page 118, Ferdinand de Lesseps is

named as one of six white varieties, while the useful Foster's Seedling is omitted. Again, in the list of Pine Apples, page 242, Smooth Cayenne is omitted, though only four are named.

The nomenclature is generally accurate, and very few errors are observable. We notice, however, that under "Juvias," which the author adopts in preference to the better-known "Brazil Nuts," the generic name is given as "*Bertholettia*," instead of "*Bertholletia*." We commend the book to the attention of the public as affording much pleasant and instructive reading, and as an example of its style we give the following extract relative to two fruits very greatly in demand at this time of year.

"Widely dispersed over the world as the Vine is in itself, there are very few localities where the preparation of raisins can be accomplished successfully. Particular kinds of soil are necessary for the Vines, and the conditions of climate where the fruit can be cured are rare and limited. For perfect results, the Grapes must be dried in the open air, in contact with a dry and heated soil, in an atmosphere void of all dampness, secure from rain and dew, and saturated, for the time being, with the hottest sunshine. These conditions are combined in certain parts of Spain; at their best, it would seem, exclusively near Malaga. Round about that celebrated city the country is very rugged. Beyond about six miles from the town, every spot where it is possible to insert a Vine is utilised. Every hill is covered, especially near the sea, and every bunch is converted into the admirable sort we import under the name of 'Muscatels.' Muscatels are often called 'Raisius of the Sun,' because originally, it would seem, after the stalks of the bunches had been partially severed, so as to interrupt the natural flow of the sap, they were left upon the tree to dry in the sunshine before gathering. In Spain, at the present day, the more usual practice is to cut the bunches when properly ripened, then to dry them in the sun upon hard earthen floors, specially prepared, and which can be covered in case of rain. Two or three other parts of the world have latterly become important as producers of Raisius similar to Muscatels. Very good ones are prepared in Fresno county, California, by cutting and laying the bunches to dry in the sun, in shallow trays, for about a fortnight. Near Huasco, in Chili, there is a little valley, where many tons of first-rate Raisins are annually prepared, the seeds so small as to be hardly noticeable. Excellent Raisins are prepared also in some parts of northern Persia and Bokhara.

"Valentia or pudding Raisins are imported, like the Muscatels, from Spain. But while the latter attain perfection only near the sea, the Valentias are raised in the interior of the country, and from an inferior description of Grape, with a thicker skin. The bunches when cut are either hung upon lines or laid out upon the ground separately, turned over once, any of the berries that have spoiled being then picked out, and in fifteen days gathered up again. A lye of wood ashes and barilla, medicated with salt and oil, is then prepared, and into this the bunches are dipped. The action of the lye causes the saccharine element of the fruit to exude in part to the surface; hence the peculiar brown and varnished appearance of the pudding Raisin, as well as the stickiness which distinguishes it from the aristocratic Muscatel. The Spaniards are well recompensed for the pains and trouble they bestow, since their fruit trade with England alone, all sorts included, is worth annually no less a sum than £1,500,000 sterling.

"The very sweet and nice little Raisins called Sultanias, light in colour, and destitute of stones or seeds, are received from Smyrna, in the vicinity of which town they appear to have been cultivated for between two and three hundred years. There is no essential difference between the Vine which yields them and many other varieties producing small and seedless Grapes. The special character of seedlessness seems to be correlative with the diminished size of the berry, and may have been originally induced by special circumstances of soil and climate, leading to partially abortive flowers. The Vines are planted in rows 6 or 7 feet apart, and at intervals of 3 or 4 feet, and so trained as to form irregularly branching little bushes, which seldom attain the height of a yard. They are grown almost exclusively upon the hippurite limestone of the neighbourhood, up to an elevation of about 400 feet above the sea. The harvest commences about the middle of July, and occupies nearly a month in the gathering. The bunches are dipped, like those of the Valentia Raisins in Spain, into a lye made of wood ashes, to which has been added a small quantity of oil. They are then dried upon the ground, a process occupying nearly a week, after which the berries are stripped or shaken from the stalks, and packed in the drums in which they arrive for the shops. The quantity brought to England is about 10,000 tons annually.

"Another variety of the Vine furnishes the inestimable fruit so familiar, in the dried state, under the name of Grocers' Currants, or, when we are speaking of their uses for cakes and puddings, simply as Currants. Little or nothing is known of its earliest history, though the plant was certainly in cultivation before the time of Queen Elizabeth, Sir Walter Raleigh being said to have had some sort of monopoly of the importation into this country. These are the genuine and original "Currants," the word being a corruption of the epithet in *uvæ Corinthiacæ*, "Corinthian Grapes," by which name they were called when first brought from Greece, the native country. The geographical range of the successful culture, like that of the Muscatel Raisin, is very limited, and from similar causes. The metropolis of the district in which the plant flourishes is Patras, whence the fruit has sometimes the appellation of the Patras Currant. Of the 86,500 tons exported from Greece in the thrice-famous Currant year, 1876, when all the veg-table products of Greece were exceptionally abundant, 71,000 were the produce of the Morea, including a few grown in the neighbourhood of Missolonghi. The balance of 15,500 was despatched from the southern Ionian islands, including Zante and Cephalouia. Corinth, singular to say, produces none at all, though the Grape is successfully cultivated there for wine-making. The actual localities of the cultivation are confined to a narrow belt of country near the coast. The vineyards are mostly within 150 feet of the sea level; they rarely exceed 400 feet; the elevation is thus markedly lower than that to which ordinary Grape culture may be carried. The vineyards best cared for present a quite unusual air of neatness and finish. The Vines are planted in rows 6 feet apart. A single shoot is trained to a stake a yard in height. As soon as it is strong enough to stand alone, the stake is removed; the training of the branches is then so conducted as to give six or seven beautiful radiations of leafy shoot, which collectively produce, in due season, from fifty to ninety bunches. If an occasional prop should be

needed, owing to the weight of the fruit, this is supplied, but nothing more.

"Towards the end of July the fruit is ripe. The gathering extends over three or four weeks, the bunches upon the secondary shoots being somewhat later than those on the primaries. In six or seven days after being laid to dry, the berries begin to loosen themselves from the stalks, and in ten or twelve days all are free. Originally the bunches were laid out upon the bare ground, a piece being specially smoothened and cleaned for the purpose. Now the bunches are laid in wooden trays, 6 feet long by a yard wide, and just deep enough, say 3 inches, to hold a single layer. When the stalks have been winnowed out, the fruit is trodden into barrels ready for shipment.

"The botanical origin of this most interesting little fruit would seem to have corresponded with that of the Sultana. The diminution in the size of the berry ensued, we must suppose, upon some special local conditions, which led in the first instance to partially abortive flowers, accompanied by failure of perfect seeds. The seedless character of the great mass of the annual produce is, after all, by no means without exception. Individual berries often contain one or two seeds that will grow. In some localities there is a decided tendency to the production of perfect seeds. When, a few years ago, Currant culture was attempted at Leghorn, it failed through the plants, after three or four seasons, producing berries as well charged with seeds as the typical Grape. Similar disappointment has been experienced in Sicily and in Malta."

"The total imports of Raisins and Currants, taken together, into England, in 1880, amounted to 1,215,436 cwt., of the value of £1,801,860."

GREVILLEA ROBUSTA AND ACACIA LOPHANTHA.

THE Grevillea ranks foremost among the many useful foliage plants, being suitable alike for conservatory, table, and room decoration. Acacias are objected to as table plants on account of the leaves closing in the evening, or what is called sleeping by many people. This makes these plants most interesting to some, while to others it proves very distasteful, as in this state they present a very peculiar appearance. They are quickly affected by light, whether natural or artificial, for some observers have noticed when suddenly exposed to bright lamp or gas light, that the leaves would partially open, and then close again. Seed of both the above-named plants can be obtained of any seedsman at a very moderate cost, and is easily raised, provided a warm temperature can be given. The seed should be sown in finely sifted soil, with a good quantity of sand added, and stood in a propagating frame or under a bellglass, or failing this, some moss might be spread over the surface of the pot. Whichever plan is adopted, care must be taken that the seedlings are not left too long, or they may become drawn, this detracting from their beauty and usefulness for house decoration.

As soon as the plants are large enough they should be placed singly into small 60-sized pots, kept close for a day or two, after which they should be placed on a shelf as close to the glass as possible. When established in these they may be shifted into 5-inch pots. These will be found quite large enough for ordinary uses indoors. Plants can be grown in this size pot to from 1 foot to 3 feet in height, and this too in a very short space of time, clothed with foliage down to the soil. Neither Acacias or Grevilleas are very particular as to soil, but will grow in peat or loamy soil with a little leaf mould or decayed manure added.

In the flower garden in summer both the plants are frequently used with good effect for sub-tropical planting, and also for the more formal carpet or geometrical design. Either may be grown to sufficient size for the latter form of planting if sown in January and grown on quickly in a warm structure. When they become too tall they may be cut down to within 4 inches of the soil, and allowed to form a bush-shaped plant; these, if kept restricted as to pot room, would make serviceable plants for the conservatory. Old plants, or any assuming a sickly appearance, ought to be thrown away and replaced by younger ones; in fact, to keep up a good stock some seed should be sown every year. Acacia seed would be found to germinate more quickly if sowed for a time in warm water previous to being sown. Liquid manure and soot water are both good in promoting a healthy growth. Among artificial manures we have found fish guano most serviceable for many kinds of foliage plants.—S. B.

HARDY FRUIT GARDEN.

THE Pear Conference will probably lead to a more extensive culture of this popular fruit, and by cordons this can be done with remarkable facility. But we are bound to caution beginners not to be misled by published lists, for if anyone supposes that the list of the fifty Pears exhibited the greatest number of times contains the best varieties in cultivation they will be mistaken. Out of the fifty, experience has taught us to regard thirty as only second-rate sorts. Take, for example, the leading sort, Beurré Diel, of which 194 dishes were exhibited. It is undoubtedly very prolific of fruit, but we have never tasted a fruit of it that was worthy to take rank with our best Pears. It is, nevertheless, good. Of the fifty sorts enumerated, the best are Marie Louise, Winter Nelis,

Passe Colmar, Josephine de Malines, Doyenné du Comice, Beurré d'Aremberg, Beurré Hardy, Comte de Lamy, Knight's Monarch, Beurré d'Amanlis, Beurré Snperfin, Général Todleben, Conseiller de la Cour, Thompson's, Napoleon, Glou Morceau, Van Mons Leon Leclerc, Huyshé's Victoria, Gansel's Bergamot, and Baronne de Mello. We have grown almost all the Pears recommended by the Committee, and have found many of them good, but not all of them, and such would probably be a very general result. No fruit is so fickle as the Pear. Soil, climate, seasons, all affect it, and a Pear that is excellent one year may be almost uneatable the next. But we nevertheless plant every new sort we can get, for there is nothing more interesting in a garden than a collection of cordon Pears, and the inferior fruit can be rendered delicious by stewing. Depend upon it there is a wide field among Pears for the fruit-grower to explore, and many treasures rich and rare to be discovered among sorts little known. Fondante de Charnéu is one of our most delicious Pears; the tree is very hardy, robust, and of free growth, but how seldom is it met with! The delicious little Dana's Hovey is another somewhat scarce sort, but it is making its way. Summer Beurré d'Aremberg is indispensable, and why do we not more often see those fine sorts Red Doyenné, Doyenné Defais, Jewess, and Comte de Flandre?

Greater attention should lead to better results. Really fine Pears are by no means so common as they ought to be; plenty of fine fruit of the best sorts must be our aim. The Pear Conference will do good work if it only shows something of our faults and failings, and points to the importance of a more general trial of sorts little known. To produce fine fruit we must have robust wood growth, and it is found to answer best if we first of all strive to bring our trees to an advanced state of development before suffering them to bear much fruit. They will then continue to yield full crops of really fine fruit if spur and branch growth is kept thinned and the fruit is also thinned. Deep, fertile, well-drained soil is indispensable to the production of high-class fruit. For cordons a border 4 feet wide and 2 feet deep answers perfectly, the whole of the border being made ready before the planting, as the cordons are only 18 inches apart and the roots soon meet and become interlaced. On lofty buildings they are trained vertically, on walls and low buildings diagonally, at an angle of 45°. It has been so clearly proved that fruit from trees trained against walls or buildings is superior to any other in appearance and flavour, that cordons should be planted in every available space, and it is surprising how many may be so planted if the sides of outbuildings are turned to account; and although it is undoubtedly picturesque to see Ivy-mantled walls and flowering climbers, yet most people prefer a supply of wholesome and delicious fruit.

FRUIT FORCING.

FIGS.—Early Trees in Pots.—When the terminal buds have fairly broken advantage may be taken of mild weather for increasing the temperature, as the Fig when fairly started into growth delights in a good heat, plenty of moisture, and all the light that can be secured to it. The increased temperature will be the more beneficial if it can be obtained from fire heat combined with solar influence by day in preference to making any great advance by night. The glass under any circumstances should be kept perfectly clean and as free as possible from condensed moisture by changing the atmosphere, especially in the early part of the day. Syringe the trees and walls twice a day according to the state of the weather, and damp the floors in the evening when the weather is dull and unfavourable to the afternoon syringing. See to the fermenting material, and if the heat exceeds 70° to 75° turn the material over as a means of reducing the bottom heat and setting moisture at liberty. Maintain the night temperature at 55° to 60°, give a little air at 65° when the morning gives promise of an increase from sunshine, and keep through the day under sun heat at 70° to 75°, closing sufficiently early for the house to run up to 80° after shutting up.

Early-forced Planted-out Trees.—If the house has been closed and a good body of fermenting material has been introduced but little fire heat will be required by night until the buds show signs of swelling, particularly when the trees have been started about the same time for a number of years; but in the case of young trees that have not been forced they will require a somewhat higher temperature to cause them to break freely. Syringe twice a day with tepid water or a few degrees warmer than that of the house, and if found necessary to repeat the watering at the roots use water at a temperature of 80° to 90°.

Succession and Late Houses.—Thin the wood that has reached the extremity of the trellis, wash the trees well with warm soapy water, and in the case of scale having appeared a wineglassful of petroleum to a gallon of water may be used with advantage. Thoroughly cleanse the woodwork and glass, and limewash the walls. Remove the old mulching if not already done, and supply a layer of good manure about 3 inches thick. Keep the house dry and cool.

Young Pot Trees.—Make preparations for potting young plants intended for forcing twelve months hence, using good fibrous loam, with a fifth of old mortar rubbish, and a little or sixth of thoroughly rotted cow dung. Train to a clean, straight, single stem, and allow the radiating shoots to form the foundation of a good pyramid. If wanted for early work another season they should be placed in gentle bottom heat by the middle of January in order that they make and properly ripen their growth by the early part of September, it being essential that they have a few weeks' rest before being again started into growth. Cuttings or eyes of kinds to be increased may now be inserted.

PINES.—In order to insure a supply of fruit during what is known as the London season, the plants which are to afford it should be brought together for the purpose of inducing them to come into fruit sooner than

they would under other circumstances. If this should be necessary provide a light pit or house, as the case may be, where they can have more heat both top and bottom than they would have in other quarters. This being effected, the fermenting material placed in, and the structure put into thorough going order, select a batch of plants from amongst the successional, choosing those which indicate signs of speedily showing fruit. These are quickly distinguished by an examination of the centre or heart of the plant. Those most likely to throw fruit soon will have few leaves in the centre, and it will be more open and stout than those which have growth to make before showing. The plants should be plunged in a bed constantly kept at about 90° to 95° at the base of the pots. If the plants are at all dry they should be copiously watered, but in no case ought water to be given until the plants become dry, which should be ascertained by the examination of each individual plant with the hand, and then a thorough supply given when needed. Maintain the top heat at 65° to 70° at night, and 5° more by day, with 10° to 15° rise from sun heat. Keep the atmosphere about the plants in an invigorating and genial state by syringing and damping as may be necessary.

PLANT HOUSES.

Allamandas.—One or more of the earliest rested plants should be started into growth without further delay if the flowers are required early in the season. It flowers profusely over a long period, and nothing is gained by starting them into growth late in the year unless flowers are required through the winter. If the plants to be started have not been pruned it should be done at once. The system to be practised depends upon whether the plants are large enough, and if so, they should be cut close back from where they started last year, leaving only one or two eyes on last season's wood. On the other hand, when necessary to increase the size of the plant, either for covering a trellis or for training up the roof of a stove, the shoots may be left several feet in length according to the ripeness of the wood and the space to be covered. If the plants are in pots turn them out and reduce the roots by one-half, and then, if dry, soak them in tepid water. After they have thoroughly drained they may be placed in the same size or larger pots. Drain the pots liberally, and press the compost firmly round the old roots. Care must be taken to leave plenty of room in the pots and a rich top-dressing during the growing season. After potting, plunge the plants in bottom heat that ranges about 80°, and where a night temperature of 65° is maintained. They will do without bottom heat, but they start more quickly by its aid. Syringe freely two or three times daily, but great care must be taken in watering them at their roots until they have taken possession of the new soil. Those in borders or tubs should have as much of the surface soil removed as possible, and fresh fibry loam and one-third of decayed manure supplied. One-seventh of manure will be sufficient to mix with the loam for those that are potted. If the loam is of a heavy nature sand may be added.

Bougainvillea glabra.—Plants that have been resting for the past two months in a temperature of 50° may now be pruned and started into growth for early flowering. In pruning cut out all the thin twiggy wood and leave the strong well-ripened wood instead. Nothing is gained by allowing the plants to become crowded with weak wood, for it will not flower. If those to be pruned are as large as required, whether grown in pots or planted out, the shoots may be spurred back and the main branches trained into position. These may be potted and top-dressed at pruning time the same as recommended for *Allamandas*, the same soil being also suitable. The conditions recommended above will be suitable for starting these plants into growth.

Stephanotis floribunda.—Plants with well-ripened wood that have been enjoying a good period of rest under moderately cool conditions may now be introduced into heat to start them into growth. If the plant to be started is in a good-sized pot, and it is not desirable to place it into a larger one, the surface soil should be removed and the plant top-dressed with equal portions of loam and manure. Above this a good surfacing of cow manure that has been stacked for some months may be placed and the ball of the plant well soaked with tepid water. Plants in large pots well filled with roots generally make short sturdy growths and flower profusely if grown in a light position close to the glass. If, however, the plants need potting they should have as small a shift as possible. The pots to be used must be clean and well drained. A portion of the old soil must be picked out carefully from amongst the roots without disturbing them more than possible. The soil used should be pressed firmly round the old ball, and may consist of fibry loam, one-third of peat and about one-seventh of manure, with a liberal dash of coarse sand added. If possible, plunge the pots or arrange them close to the glass, so that when they commence growing the new shoots can be trained close under the glass and exposed to every ray of light and sunshine. This plant should be thoroughly cleaned, if mealy bug or other insects exist upon it, before introducing it into heat.

appointed, and it seems a great pity that this rule does not hold good with us, as children are very much interested in anything that belongs to natural history. The Art and Science Department at South Kensington recognise bee-keeping as one of the subjects of minor agriculture, but it is rather an unknown land to most of the candidates.

How, then, can we best promote it? By articles in the various journals and by oral instruction; and we confess that we consider the latter the best means for starting people in bee-keeping, though when they once commenced the study nothing can be more valuable to them than to increase their knowledge by reading the various articles which appear in this and other journals; for although they may be rather puzzled by reading totally different views of the same subject by equally competent masters in the art, still they have to remember to prove all things and follow the best.

We can well remember the first time we tried to make an artificial swarm and what a dismal failure it was, but after having once seen it done by a bee-master we had no further difficulty. It is for this reason that the various shows which now take place all over the country, and perhaps still more the visits of experts to the various apiaries, have done so much good in advancing bee culture amongst us; and whether they belong to the British Bee-keepers' Association or not, they practically carry out its object, and it was with the view of having competent men to teach that they started the plan of having expert examinations.

Having had some experience as an examiner, we assert that no one who thoroughly understands practical bee-keeping can fail to pass the examination for the third-class certificate, though he may be unable to obtain the second or first-class certificates. All that is required of the candidate for the practical examination is to show his knowledge of manipulation, and as much of the theory as is contained in any of the elementary handbooks which can be obtained for one or two shillings. He has not to write his answers, as the whole examination consists in answering by word of mouth, so as to allow thousands of cottage bee-keepers who thoroughly understand apiculture, but who cannot explain it by writing, to pass the examination, and no one can get a second or first-class certificate without having first passed the practical examination. The second-class examination is a written one, and the candidate has to be well up in the theory of bee-keeping, while the first-class certificate is only given to those who know their subject thoroughly, and can give a lecture on any subject connected with bee-keeping which has been chosen by the examiners.

Last summer we had to reject two candidates, not because they did not know the life-history of the honey bee, but because they did not know how to handle the bees. We asked one candidate to find the queen in a bar-frame hive. He commenced by nearly suffocating them with the smoker, and having taken off the top carpet carefully, placed the smoker on the hive, and then, in trying to lift out one of the bars, knocked it down, crushing several of the bees, and, not content with this, he killed several of the bees when replacing the bars. Having failed to find the queen, though she was there, he tried to find her by shaking off the bees in the empty part of the hive at the back, and not finding her there, was going to look for her on the floorboard, and if we had not prevented him would have stepped on the queen, which was on the ground outside the hive, he having shaken her off the bar on the ground instead of into the hive. Needless to say, this candidate did not pass, though no doubt he still considers that he knows more about the practical part of bee-keeping than all the first-class experts as well as—
A SURREYSHIRE BEE-KEEPER.

USEFUL HINTS.

AFTER a few days and nights of rather severe frost we are again enjoying mild weather. Bees are abroad in great numbers searching after pea meal, and many of them sipping the water from a box of peat. The withdrawal of a sliding floor brought

THE BEE-KEEPER.

EDUCATION IN BEE-KEEPING.

In several countries bee-keeping is one of the subjects taught in the elementary schools, and the masters have to show a fair knowledge of this subject before they are

to view on the top of the *débris* numerous flakes of wax, proving that breeding has started. All my hives, except those in deep ones, have aired themselves; proving again that bees are more quiescent in deep but narrow hives than when in shallow ones.

THE MEMORY OF BEES.

On the morning of the 17th the thermometer registered 50°. The air was resounding with the hum of many bees, a fitting opportunity to give a nucleus containing about a gill of bees their freedom, as already a few were returning from the window to their little hive of 6 inches square by 4 inches deep. It stands upon the inside sill a foot from the glass, and has stood there for nearly two months with a loss of not more than four bees. Six weeks before I set them outside with the intention of giving them an airing, when a number of them flew out, but the sun became obscured and they immediately returned; so I removed them indoors, where they have been since, and where they have partly aired themselves. I now lifted the sash, and in a few minutes they made a rally, returning to their hive; but I observed a few of them flying about the place where I had previously attempted to let them have an airing, though the time did not occupy more than five minutes altogether, and the bees were not many seconds out nor many yards from their hive, showing how retentive their memory was. The moral is, Never shift bees short distances after summer weather is gone. One important thing I have omitted, but mention it now. A good deal of the shearings of the combs were lying in the front of the hive, which adhered to the bees, annoying and distressing them, I cleared away, which if I had failed to do would have caused the loss of many bees, as they will not return to their hive until their toilet is completed, and during wintry weather this cannot be performed before they are chilled. How valuable, then, are perforated floors that allow all *débris* to fall through, and keep the hive airy and free from damp.

BEE HOUSES.

That so few bees and their queen can live in good health and comfort during so cold a season is due entirely to the comfort afforded by the shelter of the house and free from draught by keeping the window closed unless when the bees are airing. This is all the difference between the right and the wrong ways of preserving the bees in health, or having them diseased, and thereby depopulating the hive. When kept in bee houses guard against draught by moveable side partitions or packing, as well as underneath, and have shutters, so that the bees may be confined in darkness, free from draught, but having plenty of air during severe weather, and better at night too; opening these only when the day is favourable until the season is advanced, so far that the bees will be unaffected by any change of the atmosphere.

FEEDING.

Where bees were attended to and properly prepared for the winter campaign no manipulations are necessary. If, however, any hive is in imminent want, prepare some syrup of a moderate thickness. Withdraw one or more combs from the hive, and first on the one side then on the other fill with the syrup, pouring it from a spouted vessel at a good elevation, then replace and cover up as speedily as possible. All that trouble may, however, be obviated if frame feeders are used, as the syrup is never away from the bees, and there being so little of it damp is not engendered, while the waxed trough is more natural than any other feeder. Straw hives will require to be held at an angle if the operation is necessary with them, or candy may be supplied, but syrup is better if properly applied.

DAMP FLOORS.

It is to be hoped that there will be few of these, especially amongst the hives of the readers of this Journal; but, if so, substitute clean dry boards at once.

FLOWERS.

It will be well from this onwards to take a note of all flowers that are most frequented by the bees and which yield most pollen, propagating the best for another season. *Arabis alpina* is a great favourite, yielding both honey and pollen, but of this there are many varieties. I have a seedling that never dies from the severest frosts; besides, it is more profuse in flower and lasts longer than the original variety. It continued in flower this year from February till October. Then I have another variety that is in flower now, and has been these two months past, which I would have preferred had it been a little earlier. Doubtless garden flowers can only assist the bees when there is a paucity of them in the fields, and this occurring in spring is the most necessary time to have them in flower and of the best varieties.

Nevertheless, it is both pleasing and interesting during the whole year to see the bees working on the garden flowers, and when these are absent much of the pleasure of bee-keeping is lost. To have flowers all the season for the bees should be the study of all. Some, however, have not ground to keep up a succession. Perhaps my plot of undug and untrod flower garden may be copied by some. It scarcely ever wants a flower and is often very pleasing. It is covered now with *Sedum acre aureum*, the plat is fringed with white *Primulas* and other low-growing plants of a hardy nature. The autumn *Colchicums* are still in bloom and have been for two months. I do not remember these lasting so long in years past. When January comes the *Aconite*, *Snowdrop*, and *Crocus* appears, followed by the *Scillas*, *Grape Hyacinths*, *Jonquils*, and *Tulips*; here and there a Dutch *Hyacinth* and other miscellaneous bulbs keeps up the display till May, when the *Hyacinthus Nonscriptus* of three varieties, white, pink, and blue of many shades, give pleasure to both bees and bee-master. When these are past several varieties of large-flowered but low-growing *Campanula* push up and spread, continuing in bloom till August. Meanwhile the *Sedum* has been kept under by pruning and by the action of its taller neighbour, and wherever a bare patch appears an annual of some sort or other is dibbled in, and thus the succession of flowers are kept up the whole year without much labour or expense. During the months of September and October the *Sedum* covers the surface, which sets off to great advantage and supports the slender stalks of the *Colchicums* lovely, yet modest, which at the time when other flowers are disappearing are very acceptable. —A LANARKSHIRE BEE-KEEPER.

THE BEST HIVE IN CREATION.

WILL you kindly tell me if the "Best Hive in Creation" is to be seen in London? Messrs. Neighbour & Son advertise the "Renfrewshire Stewarton;" is that "the best" according to "A Lanarkshire Bee-keeper's" idea or not? Your reply will greatly oblige.—L. BELSHAM.

[I cannot say whether Messrs. Neighbour have samples of the above hive at present; if not, they are likely to have them in the new year. Any hive can be used in the case, but square hives are more suitable than octagonal ones. The "Renfrewshire Stewarton" is one of the best type, and considered by many the best of all. One thing certain is that tiering hives are rapidly coming into more repute, and with persons that did all they could some years ago to disparage them in the estimation of those beginning bee-keeping. I may add that to get full benefit from the hive possessing reversible frames, it should be constructed so that the frames can be manipulated without interfering with the supers. This is accomplished by having the hive to open on the side. The frames rest upon a square frame made of angled iron, which slides upon the slide proper. For the purpose of giving slack between the supers and the hive, a wedge is wrought upon the under side of the outside of the frame, and another fixed on the inner, or side opposite the opening end. By this arrangement, whenever the bar on which the frames are suspended is drawn back a little, it drops and rises again when pushed in, similar to self-acting floors as lately described.—LANARKSHIRE BEE-KEEPER.]

G. H. Wilkinson, Commercial Road, Maritzburg, South Africa.—*Catalogue of Trees, Seeds, and Plants.*

TO CORRESPONDENTS

* * * All correspondence should be directed either to "THE EDITOR" or to "THE PUBLISHER." Letters addressed to Dr. Hogg or members of the staff often remain unopened unavoidably. We request that no one will write privately to any of our correspondents, as doing so subjects them to unjustifiable trouble and expense.

Correspondents should not mix up on the same sheet questions relating to Gardening and those on Bee subjects, and should never

send more than two or three questions at once. All articles intended for insertion should be written on one side of the paper only. We cannot reply to questions through the post, and we do not undertake to return rejected communications.

Errata.—In the eighth line from the bottom of the article on "Hotbeds," page 555, after the words "supplying fresh material," read "cover the frames at night," &c., and in the fourth paragraph, second line, read "sow the seeds."

Seedling Double Primula (Young Gardener).—It is not distinct from other double varieties already in cultivation.

Early and Late Peaches and Nectarines (W. W.).—Two good early Peaches are Hale's Early and Royal George. Late, Bellegarde and Sea Eagle. Nectarines: Early—Lord Napier and Elruge; late—Pine Apple and Victoria. These will give a succession of fruit, which is, we presume, what you require.

Golden Meg Merrilees Chrysanthemum (T. W.).—We are not aware that a golden sport from the popular Meg Merrilees has been exhibited by anyone. We trust you will be able to fix the sport, as it can scarcely fail to be a valuable acquisition. A good grower, who has carefully examined florets of both the parent and sport, describes them as "exactly alike in form, the colour of the latter somewhat like Thunberg, but a little softer, therefore all the more valuable, as being distinct."

Early Radishes (E. Wilson).—You say you have "plenty of leaves but no glass." Make a bed 3 feet or so high, and of any convenient size, covering it with 5 or 6 inches of light rich soil, supported by boards fixed on edge and resting on the bed like a rough frame. With a few strong laths laid across the bed for sustaining mats or straw shelters, and these taken off in favourable weather, you may have excellent Radishes long before they could be drawn from the open ground. In the London market gardens Radishes are accelerated by covering the open ground beds lightly with straw, which remains till the plants appear, and is then drawn off with rakes on fine days, and thrown on at night. Acres of Radishes are thus managed, and early crops are profitable.

Cannas (A. B. G.).—As you have only a greenhouse and frame you will err by starting the plants into growth so soon, as they would inevitably become too tall, and consequently tender, before you could remove them safely. They had better remain dry, or nearly so, until the beginning of April, then watered. They will then start freely, and in about a month will be dwarf and sturdy for placing in the frame. They will there need protection, and if well attended to will be in good condition for planting out towards the end of May or early in June, according to the position they are intended to occupy and the weather.

Imported Dendrobiums (D.).—The system you refer to can be successfully followed, but one which some of the most skilled Orchid growers prefer is potting the plants in a mixture of potsherds and charcoal. The principal advantage of this method is that water can be more freely supplied with less danger than in the other way. Imported plants require much care in this respect, for if they have suffered much in transit and are weak they are liable to decay before growth commences. You do not say from what district they have been obtained, but presuming they are East Indian forms, it will be better not to place them in a higher temperature at first; 50° to 55° will be sufficient until some signs of growth are perceived.

Keeping Grapes (C. H. Contich).—Your question—"Would thorough ripe late Grapes cut and bottled by the end of September keep well?" appears to be more interesting than practical. We have never found such standard late varieties as, say, Lady Downe's and Gros Colman "thoroughly" ripe—that is, with their flavour developed by the end of September, nor can we conceive how they could be profitably forced to be in the best condition then. If late Grapes that appear ripe were cut in September we should not consider they would improve in anything like the same degree as if left on the vines for two or three months longer, nor should we expect them to keep so long in consequence of the limited quantity of saccharine matter that they then usually contain. We have not tried the experiment suggested, and we shall be glad to hear what our readers have to say on the subject.

Cabbages Clubbing (E. T. H.).—The best thing you can do in order to prevent clubbing is to dig the ground deeply during suitable weather in the winter, and give it a good dressing of fresh lime in early spring, at least a month before the ground is planted. You may safely use for a dressing as many barrowfuls of lime as you would of manure if manuring the ground liberally. This should be wheeled on, a barrowful in each heap, then reduced to powder by applying a little water to it. When fallen to dust it may be spread on the surface and dug in, and the ground afterwards cropped in the usual way. The lime can be reduced to powder by covering the heaps with soil until they fall, but this takes up more time, and the weather may prove bad before the digging can be done, therefore the plan above alluded to is usually the best. During winter, or at any season when the ground is clear, it should be trenched as deep as the land will allow to more thoroughly incorporate the lime with the soil. As the work of trenching proceeds care must be taken to mix the lime and soil thoroughly, and not place the bulk of the former at the bottom of the trench as is often done in trenching. If labour is an object apply half the quantity of lime to the surface, and the remaining half may be applied again to the bottom soil when brought to the surface by trenching, but this should not be done until spring if practicable. This saves the labour of mixing the soil and lime well together when trenching; but if your land has not been trenched for years the mixing of the top and bottom soil should be practised. If you follow out this plan and apply a little lime yearly you will be able to grow Cabbages successfully on light soil.

Parsley Failing (Idem).—Parsley often fails when sown in the spring. We have experienced exactly the same difficulty as you describe, and now rely upon a supply of Parsley from seed sown from the last week of June to the end of the first week in the following month. For winter use we sow at the same time and cover with a frame in autumn, relying upon that sown outside for the following spring and summer supply. We have found it best to sow on ground that was well manured for a previous crop, working no fresh manure into the ground before the seed is sown. A week or ten

days before sowing the seed we work into the ground some soot and lime, and by this means succeed fairly well. When the plants outside do not look so prosperous as usual we sow a box or two of seed under glass in early spring and prick the plants out when large enough on a slight hotbed. About 4 or 5 inches of old potting soil is pressed firmly upon the surface of the bed, and in this the plants grow strongly, even luxuriantly, and never fail to give a good supply. The hotbed for a time is covered with a frame until the plants are established and growing freely, when they are hardened and the frame removed. We have not grown the variety to which you refer. If it is a strong grower it will be equally good both for summer and winter use. You had better sow in different portions in the garden, and you will possibly find a place in which the plants will flourish. For flavouring purposes the common or wild Parsley is as good as any, but not for garnishing, and it will grow freely in soil in which the curled varieties are liable to fail. This hint may perhaps be useful to others who experience difficulty in maintaining a full supply of this indispensable herb.

Concrete Walks (S. T. E.).—These if well made are both comfortable and durable. Late in March and all through April and May is a good time to make them; 4 inches, or, at most, 5 inches is deep enough for any walk whatever. The bottom should be formed into the same shape as the walk is to be finished, or say 2 inches higher in the middle than at the sides, before any of the materials are laid on. The old way of draining the centre of a walk, by drawing in the water from right and left, is radically bad in principle, and will not answer for the concrete system at all, as the drier the bottom the firmer the walk, and the longer it will endure. On very heavy clay land, where chalk and gravel are dear, burnt clay will make an excellent and enduring bottom to a walk; 3 inches of the burnt clay should first of all be put in the bottom and be well rolled in dry weather, then 2 inches of the concrete on the top, this to be well rolled also, and to be heavily watered the last thing in the evening; then the following morning a very thin layer of fine sifted gravel of good colour should be laid on the top of the damp concrete, and the roller passed over it several times until the good gravel is thoroughly embedded in the concrete and forms part of it, as it were. When the concrete is very wet and the good gravel over it too thinly put on, the weight of the roller will cause the white juice of the concrete to come up through the gravel, and that is the best sign. To hide that, put on a little more gravel and roll again, and when the whole is dry in two or three days a pick could hardly break the surface. On light dry lauds 4 inches is deep enough for walks, and the first 2 inches at the bottom may be laid with any of the rough materials, without chalk or lime, and the next 2 inches in concrete. The roller will press this sufficiently to allow a slight coat of clean good gravel on the top, without the walk being more than 4 inches deep in the whole. The concrete is made with any coarse gravel, with the largest stones taken out or broken, five parts or loads, and one part or load of fine chalk, all mixed well together and put on the walk, then well watered. In dry weather this is soon dry enough for the roller. The usual way is to begin this in the morning, and water every three or four yards in length as soon as the mixture is got in, and so on till towards four o'clock in the afternoon, when the whole is ready for the roller; or if it is not dry enough that day, to keep on till six o'clock, and roll it the first thing next morning, and then put the fine gravel on and roll again immediately. If the concrete is too wet it will stick to the roller; and after rolling, if it is allowed to get dry before the colouring gravel is put on, the fine gravel will not stick to the concrete, so that the state of the weather has much to do with the perfect success of the operation, and wet weather is much against it.

Names of Plants.—We only undertake to name species of plants, not varieties that have originated from seed and termed florists' flowers. Flowering specimens are necessary of flowering plants, and Fern fronds should bear spores. Specimens should arrive in a fresh state in firm boxes. Slightly damp moss or soft green leaves form the best packing, dry cotton wool the worst. Not more than six specimens can be named at once. (*G. S., Leicester*).—It is probable that the plant to which you allude is *Lantana brasiliensis*, from which an alkaloid has been obtained possessing qualities somewhat like quinine. (*B. R., Southampton*).—1, *Adiantum trapeziforme*; 2, *A. macrophyllum*; 3, *A. decorum*; 4, *A. farleyense*. (*W., Surrey*).—The Orchid is a variety of *Dendrobium Wardianum* of good size and colour.

COVENT GARDEN MARKET.—DECEMBER 30TH.

Market quiet, with light supplies.

AGRICULTURAL PROGRESS.

THE cultural details for laying down land to permanent pasture given in our last paper had reference only to foul land; and although it is neither the only nor best way of doing this work from a general point of view, yet it is undoubtedly the best course to take in the treatment of land that at one time would have been left idle as long fallow for a year. To farmers who intend laying down land next spring we say, Adapt your plans to the circumstances in which you are placed, only remember clean land is a *sine qua non*, and if your corn land is clean then by all means sow the mixture of Grasses and Clovers with a corn crop, for we can hardly recommend anyone to lose a year's crop in this work, nor is it necessary. It was only a week or two ago that we saw an exceedingly good piece of young pasture, the seeds of which were sown with Wheat last year. The yield of grain was fully 48 bushels per acre, and that, too, after close feeding off of the Wheat plant by sheep in spring. The gentleman upon whose estate we saw this admirable example of agricultural progress, has been actively engaged in laying down farm after farm in permanent pasture for the last twelve years, and an excellent pioneer is he in this work. He never allows such slovenly practices as letting land go out of cultivation and become just one bed of couch grass: he will have neither that nor any haphazard growth of native Grasses. The land has been cleaned and thoroughly stirred by steam cultivation, and then the Grass mixture has been sown either with or without a corn crop, as appeared most desirable. There has been no blind following of set rules, but each farm—or rather each field—has been treated on its merits. Winter Oats were sown in several fields with excellent results, full crops of straw and grain being obtained after the flock had been turned in to feed off the Oats closely in spring, the Grasses and Clovers coming perfectly well afterwards. Some of the young pastures have been mown from the first, but then this has been done intelligently, due care being taken to always mow early just as the Grasses were coming into bloom, and before there was any chance of seed development. All the seed has been procured from the best sources, no doubtful sample being allowed to pass muster. It may be mentioned that for the sowings of last spring all the leading seedsmen were invited to supply samples of seed subject to analysis by Professor Carruthers, but only a very few found themselves in a position to respond to it. This fact is mentioned as tending to confirm our statement of the extensive prevalence of adulteration in many of the mixed samples still brought upon the markets.

At each homestead upon the estate where such good work is being done, all the barns and outbuildings are being repaired and enlarged in readiness to afford shelter to the various flocks of sheep, for this estate will eventually become one huge sheep farm, in combination with the growth of herbage for hay and silage. No silos have been built, as preference is given to silage stacking, which next season will probably be tried extensively. The mention of sheep reminds us of the importance of the careful grazing of young pastures for the first two years. Sheep ought never to be turned into them then to roam at will, but to be passed over them in folds as often as becomes necessary, except in wet weather, when they should be kept off altogether, as trampling while the land is soft injures the young seeds. Nor must they be kept in the fold so long as to eat off the young growth too closely; but be passed over the entire pasture quickly, with plenty of wholesome nourishing dry food in troughs, no folding to be done, or sheep let on the young seeds after October till after the

second year. Some careful farmers will not suffer an old sheep to come on the seeds at all in the first year, only lambs being used for fear of harm being done to the plants. By the exercise of care in this matter we promote the growth of the young herbage, and we enrich the soil in the most economical way, avoiding heavy bills for manure. If sown with a corn crop the young seeds have the benefit of the dressing of artificial manure, which we have repeatedly advised to be given early in spring. It is really a half dressing for winter corn, the other half having been given in autumn. The half dressing per acre is $\frac{1}{4}$ cwt. nitrate of potash, $\frac{3}{4}$ cwt. nitrate of soda, $\frac{1}{4}$ cwt. steamed bone flour, $\frac{1}{4}$ cwt. superphosphate, and $\frac{1}{4}$ cwt. coprolite. For sowing with Grass seeds alone in spring or summer, 5 cwt. per acre of fish guano is frequently recommended. We have not tried it, but the gentleman to whose interesting work reference has been made has used it, and he has found the results satisfactory. It is by no means intended to recommend the laying down of the whole of a farm to permanent pasture; there must still be a fair proportion of arable land for the growth of roots and corn for feeding purposes, and for such green crops as Rye, Tares, Cabbage, and Thousand-headed Kale. About a hundred acres will be reserved for this purpose upon the estate we have mentioned.

(To be continued.)

WORK ON THE HOME FARM.

Many odd jobs are now in hand, such as trimming the sides of roads, carting gravel for repairs, tiles for drains, faggots, and timber. We seize every opportunity of doing all such extra work now, and hope to clear off arrears before spring corn sowing comes round again. There is still some ploughing to be done, but we only turn to this in favourable weather. Lime was also carted from the kiln during the frost, and we are now having our heaps of road sidings mixed with caustic lime, care being taken to turn over and mix the heap as the lime becomes slaked. Several men are now engaged in planting Holly, Yew, Box, Mahonias, and Laurel for game covert among the trees in ornamental belts and clumps; others are cutting down trees and underwood for faggots, poles, hedging wood, and other purposes. Hazel is now much in demand for making hoops, and of timber we find a prompt sale for Oak, Ash, Beech, and Willow. We have been cutting down many trees for estate purposes, especially for field gates and posts. Some large logs of Poplar will eventually be turned to account for weather-boarding, laths, and a variety of purposes inside buildings. It answers well for sides and doors of lodges if all exposed parts are at once tarred. The tar is put on hot and well rubbed in. We get tar from the gasworks at 3d. per gallon, and we are having every part of all wooden or boarded structures that is at all exposed to the weather well tarred. The condition of asphalt roofs should be looked into and hot tar put on where necessary, finely sifted sand being sprinkled thickly upon the tar immediately after it is applied to the asphalt. We have extensive repairs being done to farm buildings. This is work requiring special study, affording as it does scope for skill in improvements and any necessary rearrangements. Soundness, strength, connection, unity, and utility are among the chief features demanding close attention in such work. We may add that economy must not be lost sight of, for costly farm buildings cannot be undertaken lightly now.

REMARKS.

20th.—Dull and dark all day.
 21st.—Damp, dull, and warm.
 22nd.—Dull and hazy; cold clear night.
 23rd.—Fine bright morning; cloudy afternoon, much colder.
 24th.—Cold and bright till noon, foggy afterwards.
 25th.—Frosty morning, damp and dull after.
 26th.—Dull and overcast throughout.

A dull rainless week, with almost precisely the average temperature, and very high barometer.—G. J. SYMONS.
